From the timing of the effects on dawn and dusk, it seems clear that the episode of the *Iliad* recounts a shock by Mars in Northern Asia in 747 BC. The episode of the *Odyssey* recounts a shock by Mercury in North America in 686 BC, and thus experienced at nightfall in Greece. Electric contacts always happen at about noon local time, and thus at a location of Earth facing the Sun. The *Iliad* and *Odyssey* recount what happened at dawn and dusk, a quarter turn away from the location of the noon sun. With these details in place the respective compositional dates of the *Iliad* and the *Odyssey* can be determined as after 747 BC and alternately after 686 BC.

Note 13 --

See the article by Ralph Juergens, at [\[saturniancosmology.org/juergensa.htm\]](http://saturniancosmology.org/juergensa.htm). From this, by the look of the rilles of craters of the Moon, it might only take seconds for electrons to course through crustal material.

[\[return to text\]](#)

Note 14 --

With the second Earth shock in 686 BC the length of the year did not change at all, since we have no record anywhere of additional calendar reforms. I would suspect that the ellipticity of Earth's orbit might have changed. That allows a change in Kinetic Energy without changing the orbital period.

[\[return to text\]](#)

Note 15 --

More details and ephemeris data may be found in the Appendix "The Canopus Decree."

[\[return to text\]](#)

Note 16 --

The "Era of Nabonassar" actually starts on February 27th of the Julian calendar. Ussher relates:

"From twelve o'clock [noon], on the first day of the Egyptian month Thoth, from Wednesday, February 26th, in the evening, in the year 747 BC, all astronomers unanimously start the calendar of Nabonassar."

Ussher is here supposedly using the Julian calendar. The date matches the starting date of the Roman calendar (which we use today) as starting on March 1, the day after February 28th. The Olmec Long Count starts on February 28, 748 BC (-747), but on the Gregorian calendar. I suspect that in all these cases the actual dates are on a seasonal calendar, a Gregorian equivalent calendar.

"Starting at noon" has been the bane of Julian day chronology ever since Ptolemy. "In the evening" is the traditional Egyptian (and Hebrew) start of the day.

[\[return to text\]](#)

Note 17 --

Before 747 BC, when the Moon's orbit was 30 days, the Moon would have been on an orbit around the Earth which was considerably larger than today. There would not have been any

eclipses (lunar or solar) seen on Earth, for the hard shadow of the Moon, the umbra, decreases in size with distance, and at some distance completely disappears. This happens on occasion today because the distance between Earth and the Moon varies somewhat over time.

Ptolemy does not list all the eclipses which might have been available to him, even though certainly by AD 200 these could have been retrocalculated. Ptolemy lists ten lunar eclipses between 721 BC and 381 BC, from Babylonian sources, 5 eclipses from 201 BC to 141 BC, from Greek sources, and four between AD 125 and AD 136, from his own observations (at Alexandria). The number is certainly much less than the 400 or more eclipses which might have been visible in Mesopotamia (although, eclipses are visible only in limited and variable portions of the world).

Robert R. Newton, in *The Origin of Ptolemy's Astronomical Tables* (John Hopkins, 1985) (also, *The Crime of Claudius Ptolemy* 1977), questions the validity of many of these eclipses. Others are of a different opinion, although John M. Steele, in "A Re-analysis of the Eclipse Observations in Ptolemy's *Almagest*" in *Centaurus* 42 (2000), also questions the validity of some dates.

The point, however, is that both in Alexandria and China, records of eclipses start to appear only after 747 BC, although the earliest in both instances are in 721 and 720 BC. Some of the first eclipses of the Sun experienced in the 8th century BC were at times produced by Mars, and would have been associated with the destructive contacts by Mars. These solar eclipses would have struck terror in the people of the Mesopotamian region.

Alfred de Grazia has noted:

"When Velikovsky's Worlds in Collision appeared in 1950, many a critic leaped at it claiming that eclipses of the times before 700 B.C. were known and hence the skies had been orderly for long before then. Over the years he and his supporters put to rest this claim. No such historical record exists; there is no anomaly present."

-- De Grazia, *The Burning of Troy* (1984)

[\[return to text\]](#)

Note 18 --

In the previous era, 1492 to 747 BC, the year had been 360 days and the period of Venus was 225 days. The synodic period of Venus (the time of an apparent revolution around the Sun as seen from Earth) would be $(360 \times 225) / (360 - 225) = 600$ days.

The continued use of a 10-lunar-month calendar (from the previous era of 2193 BC to 1492 BC), after the year had changed to 360 days (and 12 lunar months of 30 days), would match the 600-day synodic period of Venus. Two rotations through 10 months would bring the year around to another heliacal rising of Venus. After six rotations through 10 months the heliacal

rising of Venus (which, I should point out, was absolutely spectacular in antiquity) would again fall on the same solar year day as 5 years earlier, $5*360 - 3*600 = 0$. Five 360-day years is 1800 days; six rotations of 10 months of 30 days is also 1800 days.

This explains why after 747 BC, when the period of the Moon no longer divided the Earth's year into equal and repeating segments, the "Venus calendar" was kept in use. Even though it fell behind a day every four solar years it was much more useful than a calendar based on the Moon.

[\[return to text\]](#)

Note 19 --

Ussher states:

"748 BC -- Rome was founded by Romulus according to the reckoning of Fabius Pictor, the most ancient of all Roman writers. This date is confirmed according to the account of the secular games held by the ancient Romans most religiously. This happened shortly before the beginning of the 8th Olympiad, on the feast of their goddess Pales, on the 10th day of April."

The 8th Olympiad is **776 - $8 \times 4 = 744$ BC**, shortly after 747 BC.

Velikovsky suggests that the changes in the Roman months were made following 747 BC, but this is not likely to be correct. Because it is certain that before 747 BC there were 12 months of 30 days in the year, the only reason to add two months to the year would be to correct the 10-month calendar held over from the previous era, when there were 10 months in the year.

Before 747 BC, all the months were 30 days, adding up to a 360-day year. In 747 BC the decision was made to start the year (March first) after the 28th day of February, since that day coincided with the disturbance (or the end of the disturbance) by Mars. But with the month of February now short by two days, and the new year five days longer, seven extra days had to be distributed over the 12 months of 30 days.

The extra days of the year were distributed to the first, third, and fifth months of the first five months of the old 10-month calendar (March, May, July) and in the same manner to the second five months (August, October, December), with the last additional day going to January.

Later Roman historians, noting the nearly symmetrical distribution of extra days to alternate months of the 12-month calendar, suggested that the emperor Augustus stole a day from February to be added to the month named after himself, August, just as Julius Caesar had done for his month, July.

The Julian calendar instituted by Julius Caesar included a provision for a leap day. February 24th was doubled, that is, used twice, to accomplish the leap day. Note that this is 5 days from the end of the month. It is five days before the day of the Earth shock by Mars.

But things are not as simple as all this. See, for example, the topic of "Roman_calendar" at Wikipedia, some of which is made up on the basis of uniformitarian principles.

[\[return to text\]](#)

Note 20 --

Assuming a 584-day synodic period for Venus based on the canonical values of the Venus calendar of the Maya *Dresden Codex* (dating at the earliest to AD 700), when the Earth's year changed to 365.25 days after 747 BC, the coincidence of an Earth/Venus calendar would have been $(5 \times 584) - (8 \times 365.25) = 2 \text{ days}$ -- representing a slippage of two days over 8 Earth years. A half period (4 years) would only displace the calendar by one day. This Venus calendar was in use throughout the world -- as for example, among the Egyptians and the Maya. It was used nominally also by the Greeks, who base their "Olympiads" on 4- or 8-year intervals, starting in 772 BC. Actual local calendars of the Greek city-states varied enormously, being based on local religious feasts and later on civil tax collection needs.

The Romans, by the first century BC, had done something similar, repeatedly shifting the start of the year by edict of the Senate so as to increase tax collection. Julius Caesar's reform in 40 BC was welcomed universally as a return to sanity. This is also why he was allowed to move the start of the year from March 1 to January 1, breaking a 700-year-old religious tradition.

[\[return to text\]](#)

Note 21--

In Mesoamerica only the Zapotecs of Monte Alban in West Central Mexico added a leap day. Apparently this was done in 607 BC, when a switch could be made to the Zapotec annual calendar without missing a day of the traditional Tzolkin calendar. See the chapter "The Day of Kan" for details.

[\[return to text\]](#)

Note 22--

The Mesoamerican Long Count calendar "completed a Baktun" on February 28, -747 (Gregorian), going to a count of six Baktuns, zero Katuns, zero Tuns, zero Uinals, and zero days (6.0.0.0.0 in Long Count notation), on day 11-Ahau, 8-Uo.

The year is the astronomical year of -747, which is actually 748 BC on the Gregorian calendar. (Astronomical dates include a "year zero," which is not used in BC/AD calendar notation.) I have quoted (as elsewhere) an astronomical date (like -747) as a historical date (747 BC, instead of 748 BC).

Additionally, because of the Mesoamerican concepts that a day does not exist until it is completed, the Long Count use of "day zero" actually signifies the first day of the new era, so that the actual era-ending date is February 27th. I should also note that I am using the Thompson "August 11" correlation for conversion to the Gregorian calendar in this instance. See the chapter "The Maya Calendar" for additional details. The "August 13" correlation

was, I suspect, instituted in the Valley of Mexico sometime around 600 BC or later. It spread to the coastal Olmec region, and most of the Maya in the Peten and the Yucatan, but not to coastal Guatemala where the "August 11" Long Count was retained to today.

[\[return to text\]](#)

Note 23--

The "Post Classical" Maya, after about AD 900, reduced their dating to a repeating cycle of 13 Katuns. This is the Maya "Short Count" calendar, where years rotate through a series of 13 Katuns (20-year periods of 360-day years), before repeating again (thus representing about 256 years). The 13 Katun periods are named after the name of the last day of the Katun on the Tzolkin day calendar. The series rotates, in turn, through the Katun names of 11-Ahau, 9-Ahau, 7-Ahau, 5-Ahau, etc., followed by a decreasing series of even-numbered Ahau days, and ending in 13-Ahau.

The texts of *The Book Of Chilam Balam of Chumayel*, translated by Ralph Roys (1932) insistently claims that Maya history starts with Katun 11-Ahau.

A Katun 11-Ahau ended on February 28, -747, Gregorian, thus starting a new era. Although we would hold that Katun 9-Ahau would be the start of the new era, in the languages of Mesoamerica it is the completion of a previous time period which marks a beginning. (See the chapters "The Maya Calendar" and "The Chilam Balam" for more details.)

[\[return to text\]](#)

Note 24--

As a comment on the validity of the date of February 26, 747 BC, for the Earth shock by Mars, Velikovsky wrote, "It is worth noting ... that the ancient inhabitants of Mexico celebrated their New Year on the day which corresponds, in the Julian calendar, to the same date [of February 26]." He quotes from J. de Acosta *The Natural and Moral History of the Indies*, which was translated in AD 1604 and re-edited in AD 1880. "The Mexicans" are the Aztecs, since the Maya celebrated New Year on July 26th when the Sun passed directly overhead in Central Yucatan. However, the quoted date is on the Gregorian calendar, not on the Julian calendar. In about AD 1550 there was a ten-day difference between the Julian and the Gregorian calendars. The date may have been converted from Julian calendar notation to Gregorian calendar notation by the translator or editor.

The information attributed to J. de Acosta does not match other sources for the start of the Aztec new year. Vincent Malmstrom writes, "the Spanish clerics Sahagún and Durán, disagreed: The first cited a beginning Julian calendar date of February 2; the second, March 1."

[\[return to text\]](#)

Note 25--

Linda Schele and David Freidel used the August 11 correlation in their 1990 book *A Forest of Kings*, but switch to the August 13 correlation with the publication in 1993 of *Maya Cosmos*.
[\[return to text\]](#)

Note 26--

Patten and Windsor quote from Louis Ginzberg, *The Legends of the Jews* (1928):

"When Rabshakah [the Assyrian commander in chief] heard the singing of the Hallel he counseled Sennacherib to withdraw from Jerusalem, as on this night -- the first night of Passover -- many miracles were wrought for Israel. Sennacherib however did not accept the wise counsel given him."

Egypt had been under Assyrian control for a number of years, an event not much recorded by Egyptians, when a revolt aided by the Sudanese king Tirhaka ousted the Assyrians shortly before 686 BC. Sennacherib's campaign was meant to retake Egypt.

[\[return to text\]](#)

Note 27 --

More than a "blast from heaven," the incident of this year (held to be either 686 BC or 687 BC) also has to be recognized for simultaneous worldwide earthquakes. But in those days no one paid attention to earthquakes.

Dwardu Cardona, in "Velikovsky's Martian Catastrophes" (Aeon 1990) wrote about this incident:

"If the sources are to be believed, the suddenness of the slaughter as the army lay resting during the night plus the 'burned' nature of the victims, with their garments remaining intact, do not imply the effects of a hurricane. But with so many contradicting reports, including that given by Herodotus, all of which invoke 'miraculous' phenomena, should any of these bizarre details be given credence? And if so, which?"

"Thus the aura of mystery remains attached to Sennacherib's last campaign but, as matters stand at present, the issue cannot be resolved by attributing any of this to a close Martian flyby which was apparently noted by no one."

The blast of wind happened almost directly opposite the location of the North American contact site of Mercury, not antipodal, but certainly in the northern hemisphere and at almost exactly the same latitude.

[\[return to text\]](#)

Note 28 --

Eric Miller, at the Saturnian Conference "Velikovsky -- Ancient Myth and Modern Science"

(1994, Portland, OR), introduced his talk with the following:

"I was going to go through Velikovsky, show that his dating of 687 B.C. for the second catastrophic event is probably an error, that Velikovsky's sources are incorrect as to his Chinese sources."

The "sources," however, are competent 19th century European astronomers.

[\[return to text\]](#)

Note 29 --

[Image: Semi-circle of compressed mountains centered on Northern Alabama. Courtesy of Dennis Cox, <http://sites.google.com/site/dragonstormproject/>]

The source is from Velikovsky and attributed to the Menominee Indians of North America. The Menominee are indigenous to Wisconsin, and thus located well away from the area of destruction. Velikovsky has, as an added detail from an original Ute source (S. Thompson *Tales of the North American Indians*, 1929), "... a huge conflagration enveloped the American prairies and forests as soon as the sun, frightened off by the snarer, returned a little on its way." The timing is absolutely correct. The event was also noted by Hawaiians and Polynesians, who recall (from their perspective) that at the onset the Sun rose and reversed itself before appearing again.

The North American site of the impact is clearly in Northern Alabama in the USA, centered on Huntsville. The particular shape of the compressed mountains follows the form predicted by consideration of the application of an initial compressive force. The "burning prairies and forests" were due to a path of electric arcing which traveled west from the "impact" location, and were noted by Plains Indian tribes.

It is quite possible that Venus played the role of Coyote in this tale. Venus was in the day sky

west of the Sun. As the skies darkened, Venus would have been seen with the cord of a snare (its plasma tail) in hand, extending away from the Sun.

Consideration of the applied torque (due to the electric contact with Mercury) in the northern hemisphere in North America, and the gyroscopic reaction torque, will support the movements of the Sun and Mars described in the text. (See Appendix B, "The Celestial Mechanics" for additional details.)

[\[return to text\]](#)

Note 30--

Velikovsky was initially uncertain about the date of the second close approach, but in the chapter "The Later Campaigns of Sennacherib," of the later unpublished text "The Assyrian Conquest," Velikovsky notes:

"In the last century scholars became aware that there were two invasions of Palestine by Sennacherib and that it is possible to discern in the scriptural record an early and a late campaign against Hezekiah. The first campaign to Palestine took place about -701. The second campaign is dated by modern historians to -687 or -686."

He sources Henry Rawlinson and, more recently, John Bright (1962), William Albright (1956 ?), and Edwin R. Thiele (1951).

Likewise Donald W. Patten and Samuel R. Windsor, in *The Mars-Earth Wars* (1996), use 701 BC as the year of Sennacherib's disaster, based on the chronology developed by Edwin R. Thiele in *The Mysterious Numbers of the Hebrew Kings* (1965, and 1951 above).

I am not at all convinced that either 687 BC or 701 BC should be used for a second Earth shock. The selection of dates hinges on the supposition that the catastrophe which befell Sennacherib at the gates of Jerusalem needs to be identified directly with an Earth shock by Mars. This is simply not so, since Sennacherib's army obviously was afflicted with a localized Ignis Coelis. Earth shocks are not required for that to happen, as subsequent history -- into the 20th century AD -- testifies. See Appendix B, "The Celestial Mechanics."

The *Chilam Balam* only has reference to the first and the last appearance of Mars. The first recorded appearance of 747 BC produced the Earth shock, and changed the orbit of the Earth. Earlier close passes of Mars (before 747 BC) were not recorded as significant, or were missing from the Day Books of the Long Count which was started in 747 BC.

Additional text of the Maya *Chilam Balam* states that some other planet showed up 9 times ("Bolon Mayel" -- Nine Fragrances), bringing flowers and perfumes. To show "flowers" the planet had to have a magnetic field. As I point out in Appendix B, "Celestial Mechanics," this was Mercury. Mars has no magnetic field. I will insist on the date of 686 BC, not 687 BC, and suggest that Mercury, not Mars, was the agent for the second Earth shock. Two

independent Chinese sources confirm the date.

[\[return to text\]](#)

Note 31 --

I will later suggest that the interactions with Mars stopped in 670 BC, when Earth's orbit became nearly circular (as noted by Rose and Vaughan), and thus Earth no longer came near the orbit of Mars -- which even today is still quite elliptical. See following text for details.

[\[return to text\]](#)

Note 32 --

It is likely that Isaiah addresses Mercury, that is, Phaethon, not Venus. Phaethon can be placed in 685 BC as Mercury. "Helel ben-Shahar," which is how Isaiah addresses Mercury, reads then as "Shining son of Dawn" (Eos), which is exactly how the Greeks addressed Phaethon.

[\[return to text\]](#)

Note 33 --

The *Popol Vuh* actually shrouds this in a narrative of the ball-playing twins Xbalanque and Hunahpu, and reads, "*And then the boys ascended this way, here [that is, toward Earth], into the middle of the light, and they ascended straight on into the sky. ...*"

The "eight days" of the inferior conjunction mentioned in the text -- the time after which Quetzalcoatl rose as the Morning Star -- are from the canonical Venus calendar. The Maya values are from the *Dresden Codex*, and were last recopied in circa AD 1200, from manuscripts dating to AD 700. The Maya values and today's values (from first eastern visibility through the following inferior conjunction) are as follows:

236 90 250 8 (Maya canonical values)

263 50 263 8 (Current Values)

both add up to a total of 584 days. The values above represent, in order:

- the visibility of Venus after first rising in the east
- the days Venus disappears after setting in the east
- the visibility of Venus after first rising in the west
- the days Venus disappears after setting in the west

After setting in the west, Venus would reappear in the east. Neither the 8 days nor the 50 days are hard and fast, since they vary somewhat with the elevation of Venus above or below the Sun, and the relative elevation of Earth. The total, which represents the synodic orbit of Venus, remains the same. The only differences in the values are due to the ellipticity of the

orbit -- which will not change the orbital period. The critics of Velikovsky should have understood that, but remained ignorant of basic astronomy.

The canonical Venus calendar of Mesoamerica is only marginally different from current observations. Of note is the longer time of the superior conjunction. The finely tuned tables of Venus predictions of the *Dresden Codex*, for which the Maya have gained some fame as astronomers, consist entirely of observational corrections to this chart. From this we could guess that the canonical values were derived at an earlier time -- long before AD 700.

William Douglas, in *Kronos* (1982), supplied the visibility and disappearance of Venus in the seventh century BC from the *Tablets of Ammizaduga*, as follows:

240.2 90 249.4 7 (total 586.6) (Section I)
245 90 245 7 (total 587) (Section II)

As the data shows, the synodic period of the orbit of Venus has decreased by 3 days since the 7th century BC. Since at that time the Earth's period was 365.25 days, the orbital period of Venus was only slightly longer than today, 225.1 days, as can be found from the formula for the synodic period, $(365.25 * 225.1)/(365.25 - 225.1) = 586.6$.

Also note that the Maya canonical values are close to the 7th century BC values. It would suggest that Venus was still on an elliptical orbit at the time when the Maya (or their Olmec predecessors) first collected this observational data.

[\[return to text\]](#)

Note 34 --

See for instance the collection of references to "a prodigy in the sky," and other notable displays of Venus, by Velikovsky in *Worlds in Collision*. Velikovsky, however, often places events in the wrong era and at times he also identifies celestial bodies as Venus and Mars, when it is obvious from the quoted texts that the references are to Venus and Mercury or Venus and the Sun.

If the flaming up of Venus and Mercury was due to a massive plasma expulsion by the Sun (as seems very likely from the follow-up reaction by Jupiter), then the Earth also would have ended up doing the same thing, but because of the Earth's magnetosphere and enclosing atmosphere, the Earth might have been spared the creation of thousands of electric burn craters. There is the contemporaneous statement by Assurbanipal, king of Assyria, about Ishtar (Venus) "raining fire over Arabia" (quoted in the text). Later Roman writers make the same claim of the Earth burning up because of the close approach of Phaethon, as did Plato.

[\[return to text\]](#)

Note 35 --

It had been assumed that the "ball" in the celestial ballgame of 776 BC was the Moon. This

was partially based on reports by Velikovsky from Roman sources that the "month" varied greatly around the time of the founding of Rome, circa 747 BC. However, the Roman "month" was a calendar measure, not the orbital period of the Moon. It was an attempt by the Romans to adjust the calendar to the new length of the year after 747 BC. It is just doubtful that the orbit of the Moon would be affected, especially repeatedly. There is also no information on this from any other sources.

Considering that Mercury shows up repeatedly during the period of 806 BC to 686 BC (as it had for periods after 3067 BC and after 1936 BC), it is more likely that it was Mercury which is to be understood as a participant in the foot race.

[\[return to text\]](#)

Note 36 --

The Olympic Games were said to have been founded by Hercules (Mars) at Pelop's tomb at Olympia in the northwest Peloponneses. An ephemeris shows a near conjunction of Earth with Mars and Venus in 776 BC (assuming Mars to be within the orbit of Earth, rather than without). Notes on this may be found in Appendix B, "Celestial Mechanics."

The Chinese Book of Shih King, the *Book of Odes*, lists a "celestial event" for 776 BC. In the 19th century it was reputed to only be an eclipse of the Sun. As a book of collected poetry, the Shih King is not concerned with celestial events. It is the only "celestial event" which entered the book. Since the Moon was on a slightly larger orbit at that time, it is unlikely that the eclipse was caused by the Moon. (No hard shadow would be cast on Earth.) Thus it might have been a planet on an inner orbit.

Another source for celestial phenomena during this period of time, the *Spring and Autumn Annals*, compiled by Confucius and completed about 480 BC, lists some 35 eclipses, almost all of which were verified in the 19th century, but includes no dates significant to conjunctions with Venus or Mars.

The games have to be understood as religious. Mars set the example in the skies of what activity among humans would keep punishments away.

[\[return to text\]](#)

Note 37 --

In the 5th century BC Herodotus placed the Trojan war in 1200 BC, a date later taken up by Eratosthenes. However, the date has been in controversy since the time of Herodotus. The Trojan War should be placed in the 8th or 7th century BC -- not in the 11th century BC. The testimony of the Asiatic Greeks, who traced their ancestry to the heroes of the *Iliad*, agrees on this. Velikovsky also makes a good case for placing the war in the middle of the 8th century BC, after 747 BC.

Following is a footnote from an unpublished document by Velikovsky on the later dating of the Trojan war. The footnote was added by Jan Sammer. The actual document expands on this considerably:

A. R. Burn, *Minoans, Philistines, and Greeks: B.C. 1400-900* (London, 1930) pp. 52-54: *"It cannot be too strongly emphasized that the traditional date of the Trojan War, 1194-84, adopted by Eratosthenes and more or less tentatively accepted in so many modern books, is absolutely worthless"* being based on Eratosthenes's *"wild overestimate of the average length of a generation."* Cf. idem, "Dates in Early Greek History," *Journal of Hellenic Studies* 55 (1935) pp. 130-146. Cf. also D. Page, *History and the Homeric Iliad* (University of California Press, 1959) p. 96, n. 159: *"(the date) given by Eratosthenes is nothing but a guess proceeding from flimsy premises which could not possibly have led to a scientific calculation."* Another writer adds: *"sober historical judgment must discard the ancient chronological schemes in toto; they are nothing more than elaborate harmonizations of myths and legends which were known in later times and have no independent value whatever for historical purposes."* (G. Starr, *The Origins of Greek civilization: 1100-650 B.C.* (New York, 1961) p. 67.

-- Velikovsky (Sammer) unpublished document at www.varchive.org

The actual dates of the war do not matter. The war was probably a fiction. It is the retelling by Homer and others which weave into the tale the doings of the planets in the 8th century BC that is of interest.

Alfred de Grazia suggests that the characterization of the heroes as berserkers, pirates, and incompetent warriors and sailors corresponds to the expected reaction of survivors of calamities of enormous scope, which removed all prior institutions of government, religion, history, and literacy.

[\[return to text\]](#)

Note 38 --

The new period of the Moon after 747 BC did not fit evenly into a solar year of 365.25 days. In the previous period, 12 months of 30 days had equaled a year of 360 days. Actually, it is my suspicion that the Roman people of Italy were still using a 10-month calendar cycle, left over from the calendar of an earlier epoch (when two 10-month periods exactly matched the synodic period of Venus). Romulus, mythological founder of Rome, instituted a 10-month calendar, says Ovid (de Grazia). There is also a claim by Roman historians, however, that the second king of Rome, Numa, added two months, January and February, at the end of the ten-month civil year, whose original names ended in October, November, and December, which translate as eighth, ninth, and tenth.

Juergens, Published in *Pensee Journal*, 1974, in two parts and available locally as [\[saturniancosmology.org/juergensa.htm\]](http://saturniancosmology.org/juergensa.htm) and [\[saturniancosmology.org/juergensb.htm\]](http://saturniancosmology.org/juergensb.htm) [\[return to text\]](#)

Note 40 --

There is a clear reference to the Olympic Games in the *Iliad*, about a chariot race, recounted by Nestor, which was recognized as an anachronism by the Greek editors in the sixth century BC. This anachronism, one of a number of instances, would date the authorship to well after 680 BC, when chariot racing was added to the foot races.

[\[return to text\]](#)

Note 41 --

Despite the universal use of the ballgame by many diverse societies in Mesoamerica over a 2200-year time span, we do not have a single description of how it was played. It was banned by the invading Spanish. All the information which has been gathered is inferential.

The Tablets of Ammizaduga

For such significant events as described in the previous chapter, we have surprisingly few accurate written records. From Mesoamerica we have the story that Quetzalcoatl set himself on fire. We do have dates from late Maya sources (the *Books of the Chilam Balam*), which can be verified against the alignments of Mesoamerican ceremonial centers (detailed in the chapter "Olmec Alignments"). Other than that we have the Phaethon legend from the Mediterranean and a few other curious documents. I'll discuss calendar dates in the year of this event later in this chapter. First I need to establish the year.

Among Mesopotamian sources we have, almost as a coincidence, the most curious and frequently misread, *Venus Tablets of Ammizaduga* -- a 21-year Babylonian record of the appearances and disappearances of Venus. Velikovsky had used the information from the *Venus Tablets of Ammizaduga* to demonstrate the erratic behavior of Venus in the era of the Exodus of Moses in 1492 BC. The *Venus Tablets of Ammizaduga* have traditionally been assigned to 1900 to 1000 BC. But an investigation by Lynn Rose and Raymond Vaughan in 1974 (and through 1980) determined that the *Venus Tablets of Ammizaduga* belonged to the 7th century BC, as others have also suggested earlier. Additionally, despite claims that the tablets represent completely confusing and erroneous data, Rose and Vaughan revealed the data for Venus to be inherently consistent.

The *Venus Tablets of Ammizaduga* are clay tablets found in the library of Assurbanipal of Nineveh, which burned down in 612 BC. Some 20 copies have been found (including some at other locations). Assurbanipal was a king of Assyria, the grandson of Sennacherib, and a collector of ancient literature. The tablets record the first and last visibility of Venus in the east and in the west, what we today call the disappearance before showing up as the Morning Star or the Evening Star. It is important to realize that the tablets record when Venus

disappeared and when it reappeared -- nothing else. They read (for example), "Venus disappeared in the east on ... remained absent ... months and ... days and reappeared in the west on..." [\[note 1\]](#)

Dating these tablets has been a problem. The only clue has been an insertion on a line of the tablet which should show the record of the second half of the cycle of year 8 (year 9 of my tabulation). "Venus was not observed for a period of nine months and four days." The data is missing and instead we find the words "The Golden Throne." [\[note 2\]](#)

"... this phrase meant 'year of the golden throne' ... a year-formula that had been used to refer to the eighth year of the reign of Ammizaduga [what an amazing coincidence], the next-to-last king during the first Babylonian dynasty [circa 1500 or 1900 BC]. ... it is located in the space that would originally have contained the rest of the observational material for the eighth year [the 9th year as shown on my tabulations]. As it is now, we have only the date of Venus's disappearance [in the east], not the interval of invisibility and not the data of reappearance [in the west]."

-- Lynn Rose and Raymond Vaughan, Kronia Conference, Portland, (1994)

The tablets are at times dismissed as "omen tablets" because the data for each year are annotated with what is thought to be omen information, like "... and there is war in the east" or, "the harvest is good." But omens traditionally read as "if-then phrases," like, "if earthquakes last all day, then there will be destruction in the land." The *Venus Tablets* do not read like this. Of course there are also problems distinguishing tenses, but the few I have seen read like contemporaneous observations.

Separate tablets have small errors of a day or so between them, as if we are looking at a collation of separate observations. But the tablets had to be important. They may have been used in a scribal school, which generally copied only important documents. And they are unique. No other planets were observed closely at that time. The movements of Venus must have been regarded as very significant.

But the biggest problem with the tablets has been the fact that the data -- the times of visibility and invisibility -- do not match the observations of today. That has been very disconcerting to astronomers who expect that the orbits of the Earth and all the planets have remained the same since the beginnings of the Solar System, 4 billion years ago. If the orbits had always remained the same, the risings and settings of Venus could be calculated back to the eighth century BC or even earlier, but backwards calculations do not match the Babylonian data for Venus. This is disconcerting because the same Babylonians plotted the stars accurately to within a few seconds of a degree, measured the length of each day of movement of the Sun against the stars during the year, kept detailed records of the travels of other planets, knew the length of the year to within 20 minutes, and could measure the latitude of cities to within a fraction of a degree. Something was wrong. [\[note 3\]](#)

The *Tablets of Ammizaduga* have been investigated and discussed in archaeological and astronomical literature repeatedly since AD 1865. A number of these studies held that the data was in error, or suggested that it was made up. The studies all assumed that the orbits of Venus and Earth were nearly perfect circles in the past, as they are today.

From 1974 through 1980 the tablets were investigated again by Lynn Rose and Raymond Vaughan, but without the bias of academic astronomy which, over a century of investigations, had simply removed data which did not fit (variously reported on in *Kronos* in 1980).

Rose and Vaughan hold the data to be from the eighth century BC, not from the reign of Ammizaduga nearly a thousand years earlier as had previously been assumed, although exact dates were not determined. (However, *I did* determine the exact dates, for which see further below.) Rose and Vaughan used the fact that the orbits of Venus and Earth did not intersect. This was an unneeded assumption based on the "collision" of planets proposed by Velikovsky in *Worlds in Collision* which could be dropped.

Schiaparelli in 1906 also dated the tablets to the 8th century BC, but based on mention of an invading Asiatic tribe which could be dated to the eighth century BC.

What Rose and Vaughan did was to normalize the data with respect to planetary orbital eccentricities. (Eccentricity is a measure of how much an orbit deviates from the circular.) That process removed the variations in actual day counts, yielding dimensionless units related to planetary eccentricities. In "normalized" form, the data tells very little about actual orbits, but it does tell of changes in eccentricities, and changes in perihelion. There is a change in the perihelion of the Earth's orbit after year 9 (year 10 and later), and a rather radical change in the eccentricity of Earth (from 0.10 to 0.0) after year 19.

Normalized, the data looks little different from today's observations. The large remaining discrepancy is the missing second part of the data of year 8, and the insertion of the phrase "The Golden Throne." [\[note 4\]](#)

The Golden Throne

I think the tablets record planetary events following the destruction of the temple of Marduk at Babylon in 689 BC, and its subsequent restoration in 680 BC. To point up the disruptions of the seventh century, Velikovsky had written that Babylon "did not celebrate New Year's day for a twenty year period" from 687 BC to 669 or 667 BC. "Eight years under Sennacherib, twelve years under Esarhaddon," Velikovsky quoted from the records from Nineveh, a sum of twenty years. He fit this period to what he thought to be the Earth shock of 687 BC as the starting date and the death of Esarhaddon in 668 BC as the end date -- also a difference of twenty years. However, it adds up to 21 years if different end points are counted -- 689 BC, the destruction of the temple at Babylon, instead of 687 BC (the second shock to

Earth), through 668 BC, the crowning of a new king of Babylon. Velikovsky never connected the 20-year hiatus of New Year celebrations with the 21-year record of the Venus tablets which he had quoted earlier in his book.

Additionally, Velikovsky does not mention that Babylon, occupied by Elam, was destroyed under an Assyrian siege in 689 BC, the temple compounds at the center were razed and left unoccupied for eight years, and not rebuilt until 680 BC. No wonder there were no New Year celebrations.

In about 695 BC, Sennacherib, king of Assyria, who later lost an army in the siege of Jerusalem (686 BC), had attacked the kingdom of Elam on the Persian Gulf, by sending ships and troops down the Tigris river from Syria. Elam, although an Iranian nation, at that time held most of Babylonia (Mesopotamia) from south of the city of Babylon to the Persian Gulf. Elam struck back with an overland expedition which took the city of Babylon from Assyrian control.

By 693 BC the Assyrian army had made its way back north to Assyria, having defeated the Elamites (in six campaigns) throughout Babylonia, except for the city of Babylon. Sennacherib spent the next 4 years on other punitive expeditions throughout the Assyrian empire, and finally in 689 attacked Babylon, then still held by the Elamites.

Babylon was taken and sacked. Some 60,000 lives were lost in the siege, according to the records of Sennacherib. The city fortifications were destroyed and the temple compounds leveled. The God Marduk was removed to Ashur in Assyria. A canal off the Euphrates was rerouted to flood the central area of the city. The center of Babylon, where the temple had been, stood empty for eight years.

Babylon had become important a thousand years earlier, in the time of Hammurabi (circa 1700 BC, in revised chronology), and, although at different times it was under the rule of different tribes, Babylon represented all of Mesopotamia. The whole region, once known as Akkad and Sumer, had become known as "Babylonia." The city God of Babylon, Marduk, had become the "King of the Gods," replacing the much older Mesopotamian God Enlil of Nippur as the region-wide God who would approve kingships and settle border disputes. Marduk had originally been a god of thunder and lightning, and can be identified with Jupiter.

Kingship in Mesopotamia had been secular since the very beginning and the concept of a "King of the Gods" was an attempt by the priesthood to impose some control over the city-states of Mesopotamia and their individual kings. The priests of Enlil at Nippur had attempted to gain control over the kings of the individual cities at an earlier time. When Hammurabi unified the country after circa 1700 BC and made Babylon the most important city, the priests again saw an opening. They elevated Marduk to the status of a region-wide God and wrote a new creation epic, the *Enuma Elish*, around the exploits of Marduk -- based on the celestial events of 2349 BC (the fall of the Absu).

At the time of Sennacherib, Marduk had been the primary God of Mesopotamia for a thousand years. He was recognized throughout Babylonian Mesopotamia, in Elam in the south, and even in Assyria in the north. Even later, Cyrus, the Persian, paid homage to Marduk when he took Babylon in 539 BC. All the Gods of Mesopotamia came to Babylon ("The Gate of the Gods") to honor Marduk, reminiscent of the state councils often employed by the earlier earthly kings of Sumer and Akkad. The *Enuma Elish* related this new theogony, with Marduk even elevated as Creator God. On New Year's day (Spring Equinox) the *Enuma Elish* was recited at the temple of Marduk. The celebration of New Year was the most important festival of Babylon, in which the king himself participated, playing the role of Marduk.

Sennacherib's very long struggle against the Elamites, and his failures at Jerusalem three years later, added to his growing unpopularity among the Assyrians. His kingdom apparently suffered from crop failures also. His removal of Marduk from Babylon was seen as the cause of his misfortunes.

"Even many Assyrians were indignant at this, believing that the Babylonian God Marduk must be grievously offended at the destruction of the temple and the carrying off of his image."

-- *Encyclopaedia Britannica*, 15th edition

Attempts were made by the Assyrian court to rewrite the *Enuma Elish* to show Marduk at fault. The politics came to a head in 681 BC. There was a revolt and Sennacherib was killed by two of his sons. The two sons had to flee the country and were pursued by Esarhaddon, the son of Sennacherib's surviving wife. He was subsequently crowned as King.

Esarhaddon immediately made amends for his father's behavior and in 680 BC rebuilt Babylon and the temple compounds, although the statue of Marduk remained in Ashur. He continued to maintain good relations with Babylon, spending part of the year there, but calling himself only the "Governor of Babylon." In 677 BC he installed one of his own sons, Shamash-shum-ukin, as Crown Prince of Babylon, but the prince did not assume kingship of Babylon during Esarhaddon's lifetime. [\[note 5\]](#)

Esarhaddon spends the remainder of his reign maintaining his father's kingdom. He worried much about his failing health and, at times of impending lunar eclipses, installed temporary substitute kings of Assyria so the Gods could not find him. Esarhaddon died in 669 BC while on a punitive expedition to Egypt, which was then again in revolt.

In 668 BC his third son, Assurbanipal, took the crown of Assyria and Shamash-shum-ukin was crowned king of Babylon. In the following year the Babylonian New Year festival was again celebrated. The statue of Marduk had been returned. It had been twenty-one years since the destruction of the temple. It is in Assurbanipal's archives at Nineveh that the *Venus Tablets of Ammizaduga* were found 2500 years later. [\[note 6\]](#)

There is a remarkable coincidence between the 21 years of observations recorded by the *Venus Tablets of Ammizaduga* and the 21 years without a New Year celebration in Babylon. If we place the end points of the 21 year record at the beginning and end of the period when no New Year celebrations happen in Babylon, then the year of "The Golden Throne" falls in 680 BC, the year the temple of Marduk was rebuilt.

It was the phrase, "The Year of the Golden Throne," which caused the initial researchers of the 19th century to date the tablets to 1900 or 1500 BC. However, what the insertion "The Golden Throne" strongly reminds me of is not Ammizaduga, a minor king in the declining days of the First Babylonian empire in 1500 BC, but the "Lowering of Kingship" at the start of time before the flood and again with the first king after the flood. As always, the Mesopotamians look backwards to the beginnings. [\[note 7\]](#)

"After the ... [missing text] ... of kingship had descended from heaven, after the exalted crown and throne of kingship had descended from heaven, the divine rites and the exalted powers were perfected, the bricks of the cities were laid in holy places ... "etc.

-- Ziudsura tablets, segment B, (some parts missing) circa 2700 BC.

To the Babylonians the rebuilding of the temple of Marduk must have seemed like the "Kingship of God" had again descended to Earth, and in the same manner as at the beginning of time. Most likely the Venus data was compiled to these tablets for the sole purpose of declaring how the "Kingship of God" had returned to Babylon by the will of the Gods. The data for Venus was used because the sudden blazing of Venus in 680 BC (astronomical year -685) clearly declared the event.

The beginning point of the Venus Tablets follows the destruction of the temple precincts by Sennacherib in 689 BC. A central panel which recorded the phrase "The Golden Throne" corresponds to the rebuilding of the temple in 680 BC. The end point of the data follows the coronation of Shamash-shum-ukin as king of Babylon in 668 BC following the return of Marduk.

The long delay in celebrating the New Year was due to the fact that there was no acknowledged king of Babylon until Shamash-shum-ukin was crowned and because Marduk was missing. Esarhaddon, son of Sennacherib, had taken the title of "Governor of Babylon," for political reasons, and his son had remained the "Crown Prince of Babylon." Only after 668 BC was there again a "King of Babylon." [\[note 8\]](#)

The Blazing Star

What was the year of the Golden Throne like? The account from Mesoamerica, that Quetzalcoatl "set himself on fire," suggests an absolutely astounding sight. After having set in the east early in the year and a month late (I'm not certain what calendar month), as noted

by Rose and Vaughan, Venus became visible after having passed from behind the Sun and started to appear in the day sky, following the Sun across the sky for some 60 days, blazing for 40 days, together with Mercury which suddenly became visible in the daytime sky. It was as if Venus was on fire, an apparition as bright as the Sun, climbing up with the Sun on rising in the east, blazing through the day skies, initially trailing the Sun and progressively moving away from the Sun, until it "lit up the western night sky" at dusk after the Sun had set.

Normally after disappearing in front of the Sun in the west, Venus remains out of view, caught in the glare of the Sun, for about 8 days. After disappearing behind the Sun in the east, however, Venus remains invisible for an extended period of time. This is both because of a longer path it has to travel behind the Sun, and because the Earth keeps moving, making the disappearance even longer. Today Venus remains hidden for about 50 days (it varies somewhat with the inclination of its orbit). At the time of the *Venus Tablets of Ammizaduga* it varied wildly and inexplicably. Velikovsky quotes some figures from the *Venus Tablets* which range from 2 months to 9 months. Even the passage in front of the Sun is at times far too long. But, with both the Earth and Venus on elliptical orbits, this is to be expected. Under the concept that the orbits of Earth and Venus were the same in the 7th century BC as today, this becomes inexplicable. Records from Hindu sources apparently concerning the same dates show the same inexplicable variation -- the *Panchasiddhantika* tables, transcribed 200 years later and published in AD 600. There are Egyptian data also concerning the changes in the sky (the *Ramesside Star Tables*).

Today Venus is on a nearly circular orbit. We do not know when the orbit changed, for over the next 1000 years, the Babylonians had stopped looking, the Europeans had no interest, and the Arabs had not started observations yet. Only in Mesoamerica were observations made. These show up in the *Maya Dresden Codex*, a 13th-century AD document which uses observational values dating to AD 700. The *Dresden Codex* lists the disappearance of Venus behind the Sun as lasting 90 days, not the 50 days of today.

Venus extinguished, I suspect, by July 26th of 685 BC. Its coma and tail may have disappeared somewhat later. No record was made of its disappearance in front of the Sun because Venus indeed did not disappear in the west (expected in December), but rode through the skies above the Sun by a large amount, about 8 degrees. This is not an unusual condition, but it is a very large amount. Venus in this instance went almost directly from being visible in the west as the Sun was setting to being seen in the east as the Sun was rising -- without the 8 days of hiding in the glare of the Sun. For a few days it was seen both in the west after sunset, and in the east before sunset. Rose and Vaughan did not take the altitude of Venus into account, as a matter of keeping their model reasonably simple. [\[note 9\]](#)

Sources describing the blazing of Venus abound, although most cannot be dated. In a Greek "legend" Phaethon (Phaëthon), the planet Mercury, borrows the chariot of his father the Sun and goes on an uncontrollable ride through the sky. His ride ends when he is struck by a thunderbolt from Jupiter (Zeus) and placed in the sky as the Morning Star. Augustine notes the same as a secondary recollection from other sources, relative to Venus. Being changed to

the "Morning Star" is a confusing concept, for this is usually understood to be a condition of the planet Venus, although even today Venus can be seen traversing all of the sky during daylight hours. But with Mercury placed on an orbit much closer to the Sun, so that it would show as the Morning Star for about a half hour before sunrise (and also seen as the "Evening Star"), it would make more sense for Mercury to be called the "Morning Star." [\[note 10\]](#)

Once we understand the stupendous eruption of 680 BC (685 BC), we should be able to recognize other mentions of this event. As a matter of fact, Isaiah, who had asked, "How art thou fallen from heaven, O Lucifer, son of the morning!" continues on with:

"For thou hast said in thy heart, I will ascend into heaven, I will exalt my throne above the stars of God" -- Isaiah 14:12-13

It is thought that Isaiah is addressing Venus (Lucifer) as a self-willed animate phenomenon. But it seems much more likely that he is addressing Mercury, "son of the morning," as Hesiod also called Mercury, even though this condition (of being the son of Dawn) was only a year old in 685 BC. His text recognizes that the apparition rose high in the sky (as also noted by other sources) and expresses his contempt for a spirit who would rival God by setting up a throne above the stars. These lines would have been written after 680 BC (in Eastern Mediterranean chronology).

I should add a note about the "Golden Throne." A "throne" in antiquity is not the high-backed armchair we think of. It is, after all, a coma and plasma tail we are looking at. It would perhaps look like the presentation of the mountain of Horus between 3100 BC and 2700 BC - a vertical section of a truncated cone in profile and perhaps with distinct legs, depending on how the Sun illuminated the coma and the plasma outpouring.

Because Venus or Mercury orbits between the Earth and the Sun, for part of the time when either appeared close to the Sun, the plasma tail would be directed toward Earth and foreshortened, and the planet with its plasma would have looked more like an inverted bucket than a blazing ball with a tail stretching halfway across the sky. The rationalization of the image, of course, depends entirely on expectations. Once you see a throne in the celestial display, it will remain a throne through any amount of distortion.

The Persian Zend-Avesta (written contemporaneously, or within a generation) is filled with offers of supplication and sacrifices to Tistrya (Venus), and also evokes an image of light similar to Isaiah's text: [\[note 11\]](#)

"For ten nights ... Tishtrya, the bright and glorious star, mingles his shape with light, moving in the shape of ... [a boy, a bull, a horse]". [this phrasing is repeated three times]

"We sacrifice unto Tishtrya, the bright and glorious star who from the shining east moves along his long winding path, along the path made by the Gods."

-- *Zend-Avesta* II, "Khorda Avesta" Section 8, "Tishtar Yasht" James Darmesteter, translator (1880)

The description matches what we would expect. At this time, when Venus was still regularly seen in the daytime skies, the "long winding path" describes the loop traveled by Venus around the Sun in the daytime. This would loop and advance to the west over the course of some months. It is "long" because Venus extends some 40 degrees from the Sun as seen from Earth. The "path made by the Gods" is of course the ecliptic. Despite the "winding path" Venus stayed mostly near the ecliptic.

The ten nights (actually, days) are repeated for three different shapes. This is a total of thirty days. In the "Khorda Avesta," after a lapse of 30 days, Tishtrya engages a demon in battle, but loses during the first three days. An appeal is made to Ahura Mazda [Jupiter] for intervention -- a sacrifice to give Tishtrya strength. This happens, and on the last day, Tishtrya proves stronger. Thirty-four days have passed (there may be additional days at the end of the hymn). The time span is close to being correct. I will get back to this. [\[note 12\]](#)

There are similar descriptions of a blazing apparition among Hindu sources, describing it as a "horse without hips." Assurbanipal, the king of Assyria who reinstalled Marduk to the temple at Babylon, also witnessed the event, and wrote about Ishtar (Venus):

"... who is clothed with fire and bears aloft a crown of awful splendor, raining fire over Arabia."

The "raining fire" is noted in a number of other contemporaneous and later sources. It is the "Ignis Coelis" which will continue to fall sporadically on regions of Earth far into the future.

With this display in the sky in 685 BC, we should find similar activities among humans -- as ever in imitation of the spectacle in the skies. And we do. There are two recorded instances, dated to the seventh century, of kings in Western Anatolia committing suicide in their burning palaces -- Rusas I of Urarta, and Midas of the Phrygians, both after attacks by the Cimmerians. In Mesopotamia we have two Assyrian kings who are reported to have gone up in the smoke of their besieged palaces -- Shamash-shum-ukin in 648 BC, after a three-year siege of Babylon by his brother Assurbanipal, and Sin-shar-ishkun in 611 BC, after a siege by the Medes under Cyaxares. Ussher writes about Shamash-shum-ukin (under the identity of Sardanapalus):

"... he made a huge pile of wood in his palace court and set it on fire, which burned himself, his concubines, his eunuchs and all his riches. The palace itself was also burned to ashes."

-- James Ussher *The Annals of The World* (1650)

Croesus is reputed to also have been burned to death when Sardis was taken by Cyrus in 546

BC, although Herodotus has it that he was taken prisoner by the Persians.

As always, a touch of the supernatural is added to history. I have not found earlier instances of this, except as detailed below.

In China the last emperor of the Shang dynasty is said to have similarly set himself on fire. The Shang ends in 1125 BC, but the report is from the Chou dynasty, and may be apocryphal, in which case I would presume it was created by the Chi or Eastern Chou, and dated after the eighth century BC, when extensive historical records first appear.

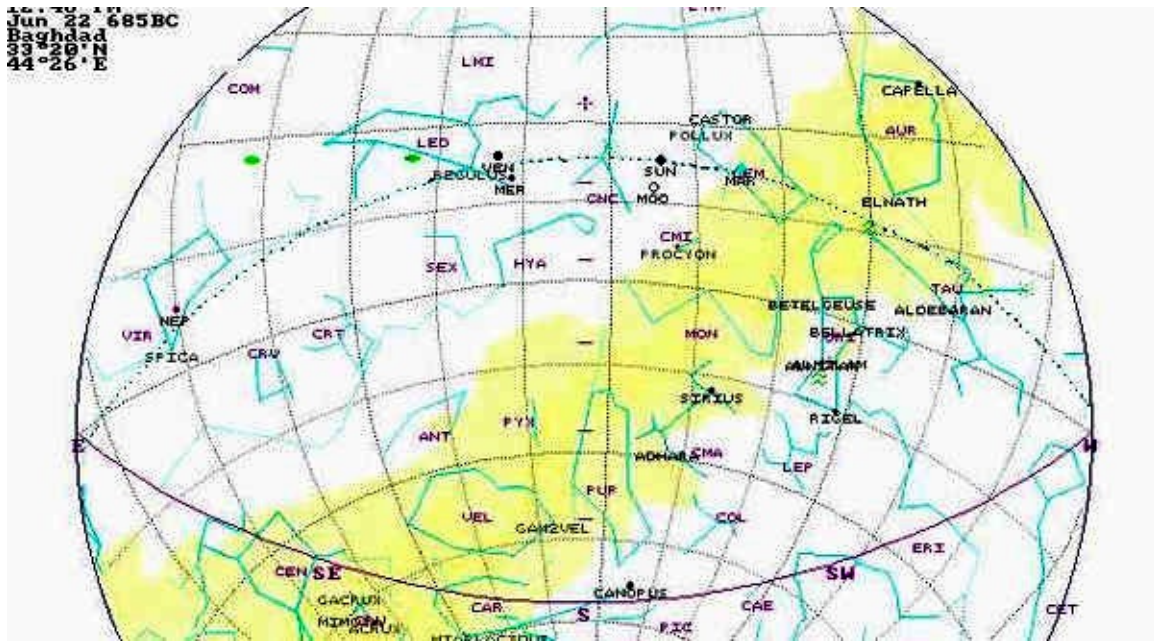

Lastly, Hercules of Greek and Roman mythology, who represents Mars, but especially the destructive visits by Mars in the 7th and 8th century BC, similarly sought deification through self-immolation. [\[note 13\]](#)

The Bolt from Jupiter

Having established the year of these events (-685 astronomical), I should at this point indicate the likely dates, the sources for which I will discuss in the next chapter in more detail. The following seems the most likely sequence of events for the year 685 BC. I'll embellish the chronology with some quotations from various sources, which I will cover in more detail later.

- In spring of the previous year Mercury made electric contact with Earth (a shock), which may have changed the shape of Earth's orbit, and radically altered Mercury's orbit. (But Rose and Vaughan did not detect a change for Earth until the following year.)
- Mercury may have altered Venus's orbit, for it would have passed Venus much closer at least twice. At the end of the year Venus disappears behind the Sun some 30 days early from what was expected, as Rose and Vaughan have noted. This has to be seen as a change in ellipticity, for the orbital period apparently remained the same. (Rose and Vaughan, however, did not detect a change.)
- On June 15 (Gregorian equivalent) the Sun went into high activity, for a one-and-a-half-month-long series of continual Coronal Mass Ejections (CMEs), hurling billions of tons of material, mostly as protons, into the surrounding space. It caused unusual auroras on Earth, would reinstate the polar plasma columns, but would not change its orbit, except that the polar axis would start to incline to a different value.
- On June 15 the Olmecs note that the Sun was not setting in the proper location. "It changed its path," states the *Chilam Balam*. This condition would last for some 40 days, through July 25th.
- On June 15, a day of the new Moon, Venus and Mercury, located close together in the sky and east of the Sun and Moon, started to blaze like suns. "Two suns were seen battling in the sky," China records. Franz Xavier Kugler, interpreting the *Sibylline Oracle Books* of AD 115, which retells the same display seen in the skies (but written about 800 years later), assumes the Earth was met with two large blazing comets.

- Since Mercury was likely invisible in the daylight sky until it also started to blaze like Venus, it looked as if Venus gave birth to Mercury, who is called Phaethon in the Eastern Mediterranean. Because of the spikes of flames reaching across the sky, and with a later knowledge that Phaethon was the planet Mercury, Roman philosophers later developed a theory that comets are produced when two planets clash in the sky.
- Because Mercury in the role of Phaethon was obviously new, and probably smaller than the blazing Venus, another theory (or myth) developed that Venus (here as Aphrodite) had taken a young boy as a lover, but soon destroyed him with a blast of fire, a thunderbolt. Hesiod mentions the first, but not the second. [\[note 14\]](#)

[Image: Daytime sky at noon, June 22, 685 BC. Image from SkyGlobe 3.6.]

In the Guatemalan *Popol Vuh*, Hunahpu and Xbalanque, Venus and Mercury, sacrifice themselves in order to defeat the lords of the Underworld, and start creation.

"Watch! they said, then they faced each other. They grabbed each other by the hands and went head first into the oven."

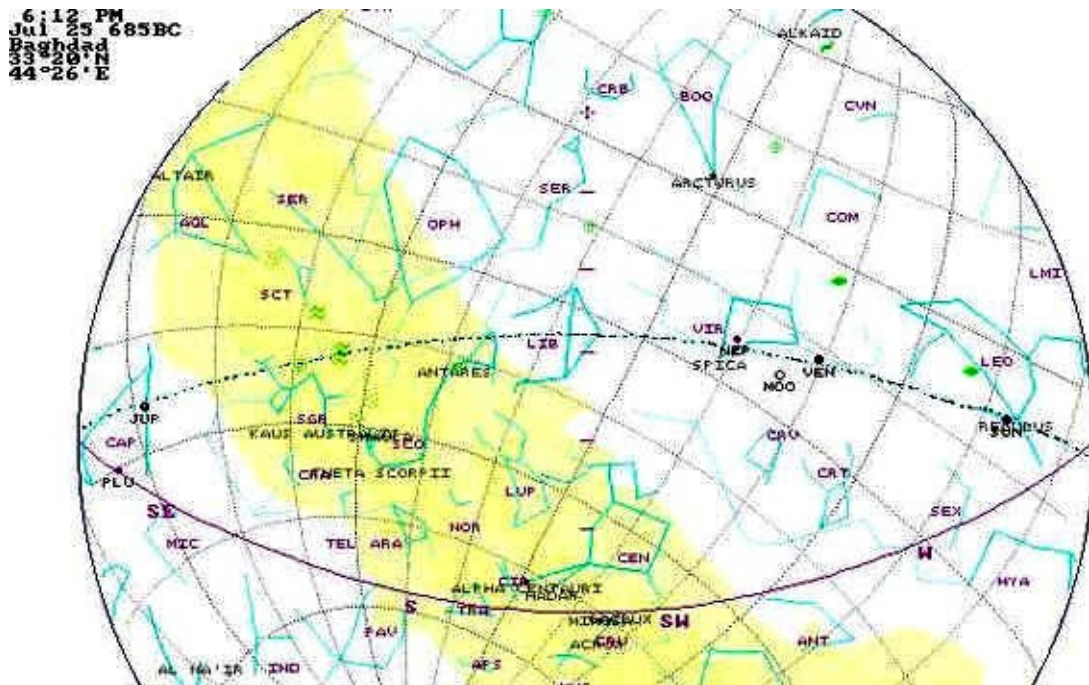

-- *Popol Vuh*

It is this phrasing from the *Popol Vuh* which allowed me to pinpoint the starting date of this event. Dennis Tedlock, translator of the *Popol Vuh*, inadvertently pointed this out when he proposed that there should be a relationship between Hunahpu and Xbalanque and the Sun and Moon.

- Immediately after June 15, Mercury, on a much smaller orbit than Venus, starts to reapproach the Sun, and passes above the Sun and on toward its west side on about July 9th. The *Sibylline Oracle Books* recall the movements of the Sun and the two planets

during the 40-day period. I'll discuss this in the chapter "The Sibylline Star Wars."

- Jupiter also received the plasma outpouring of the Sun, but because it is much larger and much further away, did not flash into a visible coma immediately. Jupiter switched to a glow mode on July 9th, producing a large coma, a three-pronged plume at its north (upper) pole and a gigantic split outpouring at its south pole (which is its magnetic north pole) -- recalled in the *Chilam Balam* and graphically recorded by the Olmecs at La Venta. In fact, on this date, the Sun, Mercury, Earth, and Jupiter were all in line. (At this time Mars was almost directly behind the Sun, and Venus was at a right angle to the lineup.)

[Image: Late afternoon sky July 25, 685 BC. A south by southwest view to show Jupiter and the Sun. The travel path of the plasmoid followed the ecliptic, and it may have looked as if Venus was hit. Image from SkyGlobe 3.6.]

- On July 14th Jupiter responded with a return lightning stroke, directed at the Sun. A massive plasmoid was released, seen and recorded worldwide. Its travel was followed for 11 days. Asia and Europe saw the plasmoid as it was approaching. The people of the Americas got a full broadside view of the plasmoid as it passed by Earth at a distance of some 30 million miles (48 million km).

On July 25th the plasmoid hit the Sun. The people of the Eastern Mediterranean saw the plasmoid again after it had passed by Earth but only saw it in the early morning (two days later), saw the east horizon light up as it landed at the Sun, and assumed that Mercury (Phaethon), which preceded the Sun in rising, had been hit -- or that Venus was the target. Mesoamerica saw nothing of the final splashdown, and assumed that the lightning bolt was meant for Mars, the nemesis during this period, located just west of the Sun in the sky. But

here, too, some opinions held that Venus had been hit.

The lightning bolt from Jupiter was, as I will show below, 1.5 million miles (2.4 million km) in diameter -- twice the width of the Sun -- and 15 million miles (24 million km) long. It would have taken some 9 hours to complete the landing at the Sun. It would have lit up both the day and night sky. The *Popol Vuh* suggests that the planets near the Sun, Venus and Mercury, were not seen for the next four days.

With that the blazing of Venus and Mercury apparently came to an end. At least, in Mesoamerica July 25 was held as the end of the event. It is possible that the arc mode plasma displays of Venus and Mercury simply diminished, switched to glow mode, and then to dark mode. Jupiter may have continued with its glow mode display longer, since a single spark will not likely "discharge" a massive planet. Apparently there were additional, lesser, plasmoids released by Jupiter. [\[note 15\]](#)

The *Popol Vuh* relates that Hunahpu and Xbalanque, after they jump in the oven of the Xibalbans, are seen by people as catfish in the river where their ashes were deposited. The river is the ecliptic, which was still aglow certainly at this time (it lasted to AD 1840). They "*looked like catfish.*" These are likely the lesser bolts from Jupiter. As will be recalled from the narrative of Egyptian predynastic history, catfish is an apt description for a plasmoid.

When I first came to a realization of the above events, I simply could not believe it, and was reluctant to put together this narrative. It is absolutely unimaginable that a planet could have bolted its star with an electric arc which had to travel 480,000,000 miles (773,000,000 km) to reach its destination. I was familiar with the plasmoid imagery of Rome and Babylon, as well as the numerous "model plasmoids" in Asia, shown in *Thunderbolts of the Gods* (2005) by David Talbott and Wallace Thornhill. The plasmoids are depicted on coins also. These images were all from late antiquity, none from before 650 BC. That was a troubling fact, for the previous depiction of a plasmoid was nearly 3000 years earlier, the predynastic Egyptian king "Catfish-drill."

I was also familiar with the "rigid bar" insignia of Maya rulers in the Classical Era (AD 400 to AD 900), but it was only when I started to look at the iconography of the Olmec site of La Venta, which can clearly be dated to before 650 BC, that I was forced to accept the fact that I was obviously looking at a depiction of Jupiter in glow mode plasma discharge (easily recognizable because of Jupiter's reversed magnetic field), and a massive plasmoid lightning bolt shaped exactly like the classical laboratory forms. The sculpted or engraved god-figure is holding the plasmoid in his arms, as all later chiefs among the Maya will also. At La Venta the first pyramid of Mesoamerica was constructed, called a "red mountain." It is an image which reflects the contemporaneous form seen in the sky at its period of creation and which recalls the much earlier celestial mountain form from thousands of years earlier.

The diverse imagery suddenly came together to explain the connection between what the Greeks considered the "mythological past" and what they and we consider the "modern

world."

The plasma bolt launched from Jupiter is the "lightning bolt of Zeus" which toppled Phaethon from his father's chariot. The myth of Phaethon is thus the last "mythology" from antiquity. In 685 BC, before releasing the plasmoid, Jupiter must have expanded and again assumed the size of a mountain. The bolt traveled over 480 million miles to the Sun. It is little wonder that Jupiter, despite its diminished visual display since 2150 BC, continued to be held as the chief God everywhere in the world.

[Images: Left: Plasmoid lightning bolt shown in its full extent. Illustration by J. Cook. Right: The end form is based on viewing the denser edge of the cup-like form and a dense central core. After David Talbott and Wallace Thornhill, "Thunderbolts of the Gods" (2005).]

We have to ask how this could have happened. What would normally happen to cause lightning between planets, is that a conductive path has to pre-exist and that the voltage difference has to be sensed. That would happen if the plasmaspheres of two planets touched.

[Image: The Plasmoid lightning bolt depicted as the "Rigid Serpent Bar" in Maya illustrations, meant as a token of office. Two Gods are coming out of the distended mouths of the serpent. The two Saint Andrew's crosses on the body denote the "vernal equinox" and "autumnal equinox" of the ecliptic. After Linda Schele and David Freidel "A Forest of Kings" (1990).]

Although the existence of a long tail would have furnished the electric path for a return lightning strike, it is just not likely that the plasmasphere tail of Venus (or Earth) would have

reached 500 million miles (800 million km) into space, through the Asteroid Belt, to Jupiter. But there is an entirely different condition which fulfills the need for a conductive media between Jupiter and the Sun, and for sensing the voltage difference.

It already was my suspicion that the "Venus nova event" was in actuality a month-long coronal mass ejection of the Sun. It lit up Venus and Mercury like suns. It was at this time that both planets ended up becoming pockmarked with craters and electric scars. It altered the spin axis of the Earth.

And it provided a highly conductive path between the Sun and the far reaches of space, certainly to the location of Jupiter -- a distance of 5.2 AU. A continuous plasma expulsion of the Sun would extend the high-voltage inversion layer which is normally relatively close to the Sun, far out into space. Rather than having to breach 500 million miles (800 million km) of a very large voltage difference, Jupiter was suddenly in almost direct electric contact with the Sun. The voltage difference between Jupiter and the Sun would be sensed by the plasmasphere of Jupiter which, like those of the other planets, actually travels within the plasmasphere of the Sun.

Earth, Venus, and Mercury were not involved in the bolt from Jupiter. Earth and Venus remained invisible to Jupiter, protected by their own plasmaspheres. Earth and Venus were also well away from the line of fire.

[*Image: Planets about the Sun, July 26, 685 BC, seen from "above." Orbital rotation is counterclockwise. Illustration by J. Cook.*]

Scaled from the diagram above, it would appear that Earth was some 30 or 40 million miles (48 or 64 million km) from the path of the lightning bolt (at a right angle). The plasmoid from Jupiter aimed directly at the Sun. The people of Earth witnessed the travel of the plasmoid through the night and daytime skies. Even if the bolt was only 1/10th of the diameter of Jupiter, it would have been the diameter of the Earth.

In November of AD 2003 the Sun sent a number of Coronal Mass Ejections (CMEs) into space. These usually travel at a speed of about 2 million miles per hour (3 million km per hr) by the time they reach the Earth's orbit (as does the Solar Wind). The CMEs of 2003 traveled across the 93 million miles (150 million km) between the Sun and Earth in 30 minutes, averaging 200 million miles per hour (320 million km per hr) -- a quarter of the speed of light. There is no reason to believe that the lightning bolt from Jupiter in 685 BC could not have traveled at a wide range of possible speeds. I'll make a speed and time estimate further below.

[*Image: Chinese depiction of the dragon. After Ramona Jablonski.*]

From a comparison of the depictions of plasmoids in Europe and Asia with Mesoamerica, it is clear that Europe and Asia saw the bolt when it was released from Jupiter, saw it travel for 10 or 12 days and entirely missed the plasmoid as it passed closest to Earth. The bolt was traveling 40,000,000 miles per day (64,000,000 km per day), so it would relocate that far between sightings. Mesoamerica had the privilege of seeing the plasmoid pass by Earth during the daytime, visually extended to its full size. [\[note 16\]](#)

The plasmoids depicted in Mesoamerica are therefore much longer than the short hand-held objects depicted in Asia, or the medium sized "thunderbolts" shown in graphics and statuary

in the Mediterranean region. The Mesoamerican plasmoid is depicted as carried in the arms of persons and looks to be a five- or six-foot long object.

China earlier, in 2349 BC, had understood plasmoids as dragons approaching from the east, and records dragons in exactly the manner in which the plasmoid was seen in the sky, head first, with an open mouth, long feelers attached to the mouthparts, and what looked like legs attached further away along the body.

Mesoamerica also recorded a dragon, but it had no legs. Instead it had heads at both ends of the body, but also with the wide-open mouth and the tendrils attached to the mouth parts as in China. What was understood as rear legs in China, was properly attached parts of the rear mouth of the dragons of the Maya.

[Image: The Plasmoid lightning bolt depicted as the "Rigid Serpent Bar" in Maya illustrations. Two planetary Gods are coming out of the distended mouths of the serpent. After Linda Schele and David Freidel "A Forest of Kings" (1990).]

Mesoamerican chiefs carry a rigid bar in their arms as an emblem of office, with triple tines at both ends. A bar like this is first shown held by a person (actually the God Jupiter) on stela 2 of La Venta and on a number of engraved dedicatory celts at the same location and period. By the time of the Classical Maya (AD 400 to AD 900), the bar is four times as thick as in Olmec times of 650 BC, and it is conceived of as a tube, a rigid snake, or a dragon with a head at each end. The tines have become mouth and jaw parts of the dragon, and Venus and the Sun are shown emerging from the two mouths.

[Images: Plasmoid models from Tibet, India, Japan. After David Talbott and Wallace Thornhill, "Thunderbolts of the Gods" (2005). Named Vajra in Sanskrit, or Dorji in Tibetan, meaning thunderbolt.]

Short hand-held "model" plasmoids, dating from this era, are found today in Tibet, India, and Japan, nearly identical to European sculptural and mural depictions, but shorter. All of them mostly follow the shape of laboratory plasma discharges: a twisted body with balls at both ends, from which emerge three tines like flower petals.

The same triple-tined objects with a twisted center are shown as being held in the hand of Zeus in Roman statues. The trident arrow appears (as the weapon of Marduk) in wall sculptures in Mesopotamia after 600 BC.

The Roman naturalist Pliny, in the first century AD, still discusses lightning bolts from planets, and distinguishes between various types. If the plasmoids had last been seen shortly after the end of the "Era of the Gods" in circa 3100 BC, it would have been unlikely to suddenly reappear in philosophical discussions during the last few centuries of the previous era to become the object of speculation.

[Images: Short Plasmoid lightning bolt depicted as vase paintings, statues, and murals (left to right: Greek, Roman, Babylonian). All dated after circa 600 BC.]

It seems clear that the difference in the images between Asia, Europe, and the Americas is entirely due to seeing this object in different stages of its travel. If Mesoamerica saw the plasmoid bolt in the day sky (with Asia and Europe turned away to the night side of Earth) just as it passed Earth, then the bolt would have been seen in full profile. From this the size can be estimated.

I would suggest that, as seen from Mesoamerica, it probably subtended an angle of about 30 degrees in the sky -- understood as a five- or six-foot long object held by a God. With the Earth 30 million miles (48 million km) from the path of travel of the plasmoid, it must have been about 15 million miles long (24 million km) ($30,000,000 * \sin(30) = 15,000,000$ miles).

In early depictions in Mesoamerica the object looks to have a diameter of about 1/10th of its length. That would make the lightning bolt 1.5 to 2 million miles (2.5 to 3 million km) in diameter. This is certainly larger by far than the diameter of the planet Jupiter (80,000 miles; 129,000 km), but the plasmasphere of Jupiter, under normal conditions, is on the order of 40 planet diameters, thus 3.2 million miles (5 million km) wide. Plasmoids also tend to shorten on cutting loose from their cathode, and thus thicken.

[Images: Left two: Long Plasmoid lightning bolt depicted on two celts from La Venta, circa 650 BC. The second figure, with the crocodile legs, is carrying a bar in the shape of snake or cayman. Right: Stela 11 at Seibal, dated 10.1.0.0, AD 849. After Linda Schele and David Freidel "Maya Cosmos" (1993), and "A Forest of Kings" (1990).]

Mesopotamia and the Eastern Mediterranean saw the plasmoid again as Earth turned back to the day side, but the plasmoid had passed by. Mesopotamia possibly saw the plasmoid contact the Sun (it would have caused a stupendous brightening in the eastern sky). Mesoamerica probably never saw the plasmoid reach the Sun, which would have required another 30 million miles (48 million km) of travel (about a day of travel), but assumed it was destined for Mars, which stood in the sky just past the Sun in the west (and would rise before the Sun the next day, obscured by the light of the impact).

From these rough estimates it could be suggested that the plasmoid was traveling at a rate of about 20 to 30 million miles per half day -- or 1.5 to 2.5 million miles per hour (2.5 to 4 million km per hr). These estimates are in line with what we know of the solar wind and normal CMEs traveling from the Sun.

How long did it take to travel from Jupiter to the Sun? Assuming that the gradient of the electric field between Jupiter and the Sun was low enough that acceleration during travel could be neglected, and at an average rate of 1.5 to 2.5 million miles per hour, it would take 8 to 13 days.

This is based on $(5.2 * \text{AU}) / (2500000 * 24) = 8.06 \text{ days}$
and $(5.2 * \text{AU}) / (1500000 * 24) = 13.4 \text{ days}$.

The people of Mesoamerica seem to claim it took 12 days. It would thus have been traveling at a rate of $5.2 * \text{AU} / 12 = 40,000,000 \text{ miles per day}$ -- 1.66 million miles per hour.

The Planets in the Sky

During much of the ninth century and a portion of the eighth and seventh century BC (806 BC to 685 BC) the skies of Earth were crowded with unwanted planets. Then, after 685 BC (680 BC in Eastern Mediterranean chronology), they all disappeared.

... Venus

Venus, without a magnetic field, would not likely have produced the tri-lobed plumed headdress shape, but only the tail of its surrounding coma, directed away from the Sun, plus a tail of sputtered particles which would split into two parts. This is seen in comets today (which also do not have a magnetic field). Additionally there might have been long wisps of plasma from its polar regions. These would seem to be coherent plasma streams, bent to the direction of the Sun, but not organized into tri-lobed plumes.

In 685 BC Venus brightened enormously, and all of these features, which had been seen for ages, suddenly increased in intensity. Assurbanipal described Ishtar (Venus) as "*... who is clothed with fire and bears aloft a crown of awful splendor.*"

I suspect that Venus lost its tail and perhaps much of its coma, because some time after 685 BC Venus was admitted as a planet in the astronomy of Babylon -- it had started to behave like a planet. A hundred years later much had been forgotten. No one remembered, or wanted to remember. History was turned into mythology.

... Jupiter

The tri-lobed plasma formation, described above, would appear at the poles of a planet with a magnetic field when in glow mode plasma discharge. Jupiter did this in 685 BC. Jupiter has a very strong, but reversed, magnetic field (ten times that of any other planet), and it produced a three-lobed flower form extending from its north pole above the coma surrounding the planet. The surrounding coma probably looked the size of the Moon.

[Images: Left: An Olmec celt, circa 685 BC, Jupiter with the body of a crocodile, holding a cayman. Shown amid the four trees (or flames) of the cardinal directions. Middle: Maya crocodile maize plant with a bird at the top, Izapa stela 25. Right: Maya crocodile tree on a blood offering plate. After Linda Schele and David Freidel "A Forest of Kings" (1990), and "Maya Cosmos" (1993).]

The same strong magnetic field produced another tri-lobed form, but much larger than the top, at its south geographical pole (the north magnetic pole), making it look as the "body" of the planet, or as a mountain, although, and as noted by the Olmecs, the body looked like the open jaws of a crocodile, the central tongue of which might have been missing or not observed. Crocodiles have only a short tongue.

These features were recorded after 685 BC by the Olmecs on stelae and engraved ceremonial celts. Archaeologists hold that the headdress is to be identified as a corn plant, with two leaves pulled away from an ear of corn. (Even though the ear of maize plants was turned down in cultivation.) But the figure universally recognized as the "Corn God" in the Classical Maya era does not wear such a hat. The tri-lobed headdress shows up, instead, and from very early times, among the Maya as the "jester hat" of a scepter or headband representing Venus, known among archaeologists as the Jester God. [\[note 17\]](#)

Jupiter in this condition was also identified as the central (or southern) tree of creation, the World Tree of the Maya. The same World Tree is often shown by the Maya with branches

and leaves at the top, but with the head of a crocodile as its base at the bottom.

The tri-lobed crown of Jupiter waved back and forth, since the magnetic poles of planets do not coincide with the rotational axis. At a rotational rate of 9 hours, the rotation of Jupiter's tri-lobed plasma outpouring would have been seen as a plant waving in the wind. Jupiter was probably also seen during the day. At Teotihuacan the favored headdress of dignitaries and Gods becomes a hat of feathers and plumes. This fashion carried through for a thousand years to the Maya and the Aztecs.

In the Eastern Mediterranean region the Gods had already taken human form, and the only strange animals depicted as supernatural beings are the demons they battle.

... Mars

In Mesoamerica Mars is often depicted as "smoking" (a cigar) or with a smoking mirror on his forehead. As I have mentioned earlier, the smoking mirror is likely the sublimation of water from the remnant upper ocean. This suggests that at some point in time Mars had lost its atmosphere, but had retained one of its oceans (the smaller ocean is within the confines of the larger polar ocean).

The smoking cigar might be an unshaped plasma discharge, or a plume of impinging electrons brought to arc mode near Mars's surface. But one wonders if the "smoking" represents the lightning bolt suspected to have been delivered by Venus in 776 BC. When Mars is depicted with an axe piercing his forehead, recognition has to be given to some gigantic impact of the past -- probably the thunderbolt excavation of Valles Marineris. Olmec sculptures depict Mars with the features of a bat and the snarl of a Jaguar, which might be additional aspects of dust lifted from the surface and shaped by the Earth's magnetic field (when Mars closed in on Earth).

At later times among the Maya, Mars (God K), is depicted with the leg of a snake, which archaeologists have determined is a symbol for lightning. That describes the effect of electric contacts after 806 BC.

An estimate of the number of visits by Mars after 747 BC might be deduced from the religious monuments at Olmec La Venta between 747 BC to about 400 BC. There are, within the confines of the pyramid and adjacent plazas, five elaborate graves (one of the graves is a coffin shaped as a gigantic cayman), five massive offering caches of serpentine blocks, and four colossal stone heads. The first passage of Mars perhaps did not require a stone head. Or it has not yet been found. The three mosaic tiled floors (two were buried) read "9 Jaguar" -- a bar and 4 dots, shaped like a jaguar face with the characteristic forehead cleft -- which in effect equates to the name used in the *Chilam Balam* for Mars, Bolon Dzacab, "Nine Lives."

Except for this repetition of five, along with the four giant heads, there is no clear record of

the number of visits. The only additional suggestion comes from the *Chilam Balam*, which records, after the first mention of the appearance of Bolon Dzacab, Mars, in 747 BC, the descent of four "mighty demon bats."

The best reconstruction by Velikovsky from Biblical sources was to suggest appearances of Mars at 15-year intervals. The 60-year time span of 747 BC to 687 BC represents five visits if they were 15 years apart. This is also the sequence of events in the Quiche Maya *Popol Vuh* -- five ballgames are played in the underworld. However, the number of visits at 15-year intervals between 806 BC and 687 BC is nine.

Despite the coincidence of "nine" in "Nine Lives" and the suggested number of close contacts by Mars, the certainty for the number nine comes from the name of the flower vendor, Bolon Mayel [Nine Fragrances], who is Mercury, and who is said to have accompanied Mars in each instance.

... Mercury

The *Chilam Balam* lists nine close calls by a planet named Nine Fragrances in the eighth and seventh century BC (probably from 806 BC to 687 BC), described as delivering flowers and fragrances. If these were being delivered by Mars, then the "flowers" are curious, because a flower-form (the tri-lobed form) would not be expected for Mars. Nor would the fragrances, for Mars has no atmosphere. This would suggest that the planet called "Nine Fragrances" was Mercury, instead. Mercury has a minor magnetic field, and still has a strange mix of gases as a thin atmosphere.

When the *Popol Vuh* describes the northern Gods after 10,900 BC, Mercury was confused with the later appearance of Venus, and called "Sovereign Plumed Serpent." But very little atmosphere would be needed to create a coma in glow mode.

The fragrances are recorded in Vedic sources also. Velikovsky mentions them, although he assigns them to the era of 1500 BC. The exterior of the plasmasphere of Mercury (the "double layer") would have included gases in ionized forms from its atmosphere. Close passes to Earth would have transferred many of these to Earth's plasmasphere, and eventually to the Earth's atmosphere.

The repeated destructions of sites in Persia, the Middle East, Greece, Italy, and apparently Mesoamerica, together with the identification of Mars, and lamentations about the followers of Mars, would suggest Mars as the main agent of the destructions of the 8th century BC. But the flower forms and the associated fragrances point to Mercury. These are not even mentioned (except for the fragrances) in the Middle East.

What I will suggest is that Mercury had been a companion of Mars since remote antiquity, so that the two would always appear together. I had already considered that Mercury was likely

the "other planet" which showed up along with Horus/Mars in the period of 3067 to circa 2700 BC to constitute the twenty-some pharaohs of the first and second dynasty of Egypt and similarly the 20 early kings of Kish in Mesopotamia. The two planets show up along with the "Followers of Horus" and the large quantities of cattle and dead people in the skies which were recorded by the Egyptians in the first and second dynasty. I have also suggested that the "sandal bearer" shown following the pharaoh on the "Palette of Narmer" is not his son, but Mercury.

The "Palette of Narmer" shows the "Followers of Horus" as six papyrus buds led out of the Duat by a nose rope held by Horus the falcon. On the obverse side are the standards of the cardinal directions, followed by a woman with a bola, Narmer as Mars, and Mercury bringing up the rear. Of course it is not certain if Mercury always followed the travel of Mars. But at any rate in the 8th and 7th century Mercury would show up near Mars at each of the 9 instances when Mars cruised close to Earth on 15-year intervals.

The 16th century AD *Chilam Balam* lists "Nine Fragrances" as he who descended when "it was that the word of Bolon Dzacab [Mars] descended to the tip of his tongue."

"With it descended Bolon Mayel [Nine Fragrances]; sweet was his mouth and the tip of his tongue. Sweet were his brains."

The "nine" of the "Nine Fragrances" represents, as these numeric prefixes do throughout the *Chilam Balam*, nine appearances of Mercury. This matches the nine appearances of Mars between 806 BC and 687 BC. By coincidence the nine appearances of Mars is the same number assigned to him before 3147 BC ("this first Bolon Dzacab"). Curiously, the giant jade or greenstone mask-shaped floors at Olmec La Venta, apparently buried as a means of warding off or appeasing Mars, represent the face of a Jaguar in the form of the glyph for "nine," were installed long before the nine close passes of Mars had been completed.

The mouth, tongue, and brains (top of the head?) of Bolon Mayel probably describe the plasma plumes above and below Mercury, and are, as a matter of fact, described in the *Chilam Balam* as flowers.

Today Mercury still has an externally induced magnetic field (it is thought), due to the fact that on its (current) orbit it travels to a distance twice as far from the Sun between perihelion and aphelion. Previous to the 7th century BC, traveling on an orbit which took it well beyond the orbit of Earth, it might have had a much greater magnetic field. Mercury also, gauging from the remaining thin atmosphere, might have held a considerable gaseous envelope, able to support a shaped plasma.

... Earth

The Earth, another planet with a magnetic field, would, at various times of excess electric

activity, also have had the same tri-lobed vortexes standing above the Earth's north and south magnetic poles, and extending perhaps 10 or 20 Earth diameters into space. The plasma above the north magnetic pole would have been larger than the plasma of the south magnetic pole. But the southern plasma was most likely visible also in the northern hemisphere, for the plumes would have bent away from Earth into the tail of the magnetosphere.

It is quite likely that the outer shell would be mostly transparent, and only the central spikes were seen. Alternately, as I have detailed in previous chapters, the plumes rose up as a coherent structure with ball plasmoids at the end and the plant-like wisps (the terminating cup and spike) beyond that. (See also an endnote to the chapter "The Gods Leave," detailing the recent discovery by NASA, in early 2009, of these plumes, in dark mode, and separated as two counter-rotating streams at the northern aurora). A plasma stream above the north and south magnetic poles would answer to the claims of the four trees of the cardinal directions of the Maya, which appeared four times since 3147 BC, according to the *Chilam Balam*. Other Mesoamerican sources claim 8 and 9 appearances for the northern plume. [\[note 18\]](#)

The Twins

The combined appearances of Mercury and Mars came to an end in 686 BC, when a line-up with Mercury caused an Earth shock and Mercury was, as I have described, jolted into an orbit much closer to the Sun. The Earth changed the location of its aphelion, as Rose and Vaughan have pointed out (detailed below), inadvertently moving it away from the orbit of Mars.

In fact, the mythological and quasi-historical tales from this era are obsessed with twin celestial Gods. With the Greeks they are the Dioscuri, Castor and Polydeuces (Pollux). Castor is a tamer of horses and mortal, Pollux is a boxer (no kidding!) and immortal. Homer places them in Sparta.

The Spartans, in fact, hold them to be the younger twin brothers of Helen. (Homer's Helen in this may be equated with Venus.) Both travel with the Argonauts at one time. They steal cattle in Arcadia and drive them east to Sparta. At the conclusion of some fights and pursuits, Zeus kills one of the pursuers with a thunderbolt. This last represents the eruption of Venus and Mercury in 685 BC.

In Italy the twins are the founding patrons of the city of Rome, Romulus and Remus, sons of Mars. This is strange, but then, Rome's historical records were destroyed in antiquity. Remus was killed by Romulus in a dispute. Romulus founded and ruled the city of Rome, and is then taken up into heaven. After 686 BC Mercury had, for all practical purposes, disappeared from the skies.

The constellation Gemini is generally held to be the Dioscuri twins, but Hyginus (in *Astronomica*, attributed to Hyginus, but dated circa AD 200) says the twins are Apollo and

Heracles (Mercury and Mars). Santillana and von Dechend mention twin deities of China, and there are without doubt others.

In the *Popol Vuh* two sets of twins are identified, first as One-Hunahpu and Seven-Hunahpu (probably an appearance of 776 BC), and then as Hunahpu and Xbalanque (the five appearances documented in the Long Count for 747 BC and after).

Talbott, in *The Saturn Myth*, notes that almost always one of the twins is white and the other is black. He references not only Greek sources, but also Mesoamerican, Indian, Chinese, and many others. Australia could be added, as well as the *New Testament* apostles James and John -- the Sons of Thunder (Mark 3:17). We could add Cain and Able as an earlier manifestation. Talbott, of course, relates the black and white aspects of the celestial twins back to the polar configuration in the north. But it should be obvious that the white twin is Mercury with a cloud cover of an extensive atmosphere, and the black twin is the dark Mars, with neither an atmosphere nor a coma except as wings of dust.

The two planets only became prominent in the skies of Earth when their orbits intersected the orbit of Earth periodically. This happened in the 8th and 7th century BC, as had happened for a period, 2200 and 1100 years earlier, after 3067 BC and again after 1935 BC. Before that, during the "Era of the Gods," only Mars interacted with Earth. Mercury hung below Saturn, initially very visible when Saturn was blazing, and probably mostly obscured after Saturn quieted down. Despite the fact that Mercury is the smallest planet of the Solar System today (our Moon is smaller), it supported an atmosphere and a coma, which would have made its apparent size much larger than Mars. Together these two would have constituted the iris and pupil of a huge celestial eye.

The Last Changes

There is another very interesting and related consideration arising from the analysis by Rose and Vaughan. They note a change in the aphelion of Earth's orbit in the year immediately following the year of the "Golden Throne" of 685 BC, thus 684 BC. The orbit of the Earth changed its shape, or as Rose and Vaughan note, the Earth's aphelion moved elsewhere in its orbit by 10 or 15 degrees. Probably the most important aspect of the change in aphelion is the fact that it immediately removed the Earth's orbit from further intersections with Mars's orbit, by rotating away from the location where it crossed Mars's orbit.

Moving aphelion by 10 or 15 degrees within the time of a single rotation around the Sun is not a small amount. This clearly is in conflict with any current theories of how orbits might change, which could only happen under the gravitational effects of other planets. Such gravitational tugging is a very small percentage of the effect of the gravity due to the Sun, and would take millions of years to have any effect.

What also happened simultaneously, as a result, was a change in the place in the heavens to

which the axis of the Earth pointed. The result would amount to a 15-degree shift of the vernal equinox (the first day of spring, and the start of the year for most nations), and thus a 15-day delay in the start of spring. Instead of the Sun rising in the constellation of the Bull, Taurus, as it had for thousands of years, it suddenly started to rise in the constellation of the Ram, Aries. I'll detail this in the next chapter.

Chaldean priests had kept records of the movements of the planets since 747 BC and certainly by 652 BC (we have records from that date), but often on differing coordinate systems. These make no sense to astronomers today. The Vedas mention a sinking of the Earth. Numerous Greek, Roman, Egyptian, Chinese, and Indian sources mention the change in the Earth axis, and even a later Roman playwright incorporates the well-known "change in the heavens" into a play -- specifically in reference to the zodiac. [\[note 19\]](#)

It was as if a power outside the dome of the stars had suddenly shifted the heavens by rotating them away from the horned bull -- the age-old symbol of the celestial Gods. This was a power greater than that of any of the Gods worshipped up to that time. It closed an era.

Although the changes in the night sky were seen immediately, the significance of the change was not initially appreciated. But within a few hundred years this entered religious and philosophical thinking in the Middle East, India, and China. It is almost certain that Buddhism can trace its inspiration to this event of 685 BC. The Persian Zoroastrianism similarly dates from this period, and strongly influenced Judaism. In China the concepts are expressed in the philosophy of Taoism. The Tao proposes to explain "the change of the path." The "mystery religions" of the Middle East and Greece date from this period. I will get back to this topic in a following chapter.

Additionally Rose and Vaughan report that 9 years later, in 670 BC, for some unknown cause, the eccentricity of the Earth's orbit changed significantly (from 0.10 to 0.0+). This means the orbit of Earth became nearly circular, and no longer overran the orbit of Mars. With that the drama in the skies was over. [\[note 20\]](#)

Endnotes

Note 1 --

Path of Venus as Morning Star and Evening Star

To explain the strange behavior of the planet Venus: Today Venus is mostly seen only at night, and never more than about 40 degrees alternately above the east or west horizon. Once the Sun rises, Venus is (generally) no longer seen.

Venus is an inner planet. It revolves around the Sun between Earth and the Sun. Its path in the sky describes its orbit around the Sun.

In antiquity Venus was seen also in the day skies (today also, but infrequently). During night hours it was seen preceding the Sun before rising (in the east), or appearing after the Sun set (in the west). In the west, in showing directly after sunset, it would distance from the Sun over the following days, that is, be seen higher in the west sky every day, and then start to come closer again, to suddenly disappear for 8 days, to then rise before the Sun in the east. In rising before the Sun, it would also slowly distance from the Sun and then return, to then disappear for some 60 days or more, after which it would again rise in the west.

Path of Venus through the day Skies,
before 685 BC

In antiquity, Venus was seen as a brilliant object near the Sun. It would seem to circle around the Sun, always with a tail pointing away from the location of the Sun. But it would disappear completely from the skies twice during its 584-day synodical period, once for 8 days, and once for 50 days as it passed in front of the Sun or behind it. These are the current values. In AD 700 the Maya recorded 90 days for the second value.

The Venus tablets stand out as a singular early record not involving any other planets, included with a cache of omen tablets known as the *Enuma Anu Enlil*. Hope Anthony, in "A Guide to Ancient Near Eastern Astronomy" (University of Texas), writes:

Enuma Anu Enlil: An astrological omen series comprising some 68 tablets. The tablets themselves were found in the Assyrian king Assurbanipal's library in the ancient city of Nineveh, and were written in the 7th century BC. However, evidence suggests the collection of omens is much older than the tablets found in the library, and the original series probably dates back to the Old Babylonian period at the beginning of the 2nd millennium BC."

"The Enuma Anu Enlil deals mostly with the constellations, or 'fixed' stars, and, to a lesser degree, with the planets. The exception to this is tablet 63, known as the 'Venus Tablet of Ammizaduga'.... Several copies of tablet 63 have been recovered in varying degrees of preservation, but a composite of these reveal the tablet to be a record of rising and setting dates for the planet Venus over a period of 21 years. As with Enuma Anu Enlil as a whole, the 'Venus Tablets' also contain omens."

Anthony gives an example of an omen text as:

"If in month I the Demon with the Gaping Mouth (Cygnus) rises heliacally: for 5 years in Akkad at the command of Irra [Mars] there will be plague, but it will not affect cattle."

The reference to Akkad places the above text to an era well before the era of Babylon or the third Assyrian empire. But by similar references to contemporary events, the Venus tablets themselves can be placed after the start of the 7th century BC.

Note 2 --

The data is not missing. Venus was not "observed to disappear" for nine months, which would have been from March through December.

Year	Invisibility During Inferior Conjunction	Invisibility During Superior Conjunction
1	3 days	
2		2 months, 8 days
3	20 days	
4		2 months, 1 day
5	15 days	2 months, 4 days
6	3 days	
7		2 months, 11 days
8	7 days	2 months, 7 days
9	9 months, 4 days	<-----
10		2 months, 6 days
11	11 days	
12		5 months, 16 days
13	7 days	2 months
14	1 month, 16 days	
15		2 months, 15 days
16	15 days	3 months, 9 days
17	4 days	
18	---	---
19	15 days	
20		2 months, 6 days
21	7 days	2 months

-- after Livio C. Stecchini, "The Twenty-One Years of Venus"
Kronos Volume 7 number 3, 1982

An ephemeris shows that rather than disappearing in front of the Sun in the west in 684 BC, Venus rode some 8 degrees above the Sun. Thus it moved from being seen in the west above the Sun, rather than in front of the Sun, to next being seen in the east, also above the Sun, without the disappearance period. This is a rare condition, and could be held as proof that the data does not belong in 1500 BC, but properly describes conditions in 684 BC as I have determined.

An ephemeris can be used because the later changes in eccentricity do not change the location of Venus or Earth by more than a few days. Both Earth and Venus were on orbits very little different from today. Also, eccentricity does not change the orbital period.

It was during the course of the previous year (685 BC, astronomical) that the planets Venus

and Mercury blazed with light.

[\[return to text\]](#)

Note 3 --

Velikovsky, in Chapter 10 of *Worlds in Collision*, presents a listing of the anomalous spans of time that Venus was visible in the east or west, and the length of disappearances, as recorded by the *Venus Tablets of Ammizaduga*. Velikovsky uses this information to bolster the notion of an irregular orbit for Venus in 1500 BC. The *Venus Tablets of Ammizaduga* indeed prove that there was no regularity at all. But Velikovsky (or anyone) should have realized that if both the Earth and Venus were on eccentric orbits then this condition would be expected. Today Venus has the most circular orbit of any planet, and Earth nearly so, and the visibility and invisibility of Venus in the sky is thus very regular.

I should also note that the idea of "visible in the east" and "visible in the west" is an erroneous notion, since in antiquity, because of its bright coma and tail, Venus moved visibly across the skies with the Sun in the daytime (in addition to showing at night after sunset or before sunrise). What was strange to our ancestors was that Venus would periodically disappear altogether -- in passing behind the Sun or in front of it. At these times the tail would shrink also and disappear, because the plasma tail would be either directed away from the Sun toward Earth or away from the Sun while behind. This strange behavior, in fact, is why Venus was watched. It was such a peculiar object that it was not classified as a planet until after 600 BC.

[\[return to text\]](#)

Note 4 --

Normalization involves dividing data points by an associated variable, which in effect removes its influence on the data. In this case the data could be investigated without having to know (for example) the synodic period of Venus or Earth. Normalization did not supply missing data, it only allowed Rose and Vaughan to test the data against various assigned eccentricities for Earth and Venus.

The background and methods were detailed in a series of articles by Lynn Rose and Raymond Vaughan, the first of which appeared in *Pensee* in 1972 as "Babylonian Observations of Venus." This was followed by a number of articles in *Kronos*: "Analysis Of The Babylonian Observations Of Venus" (1976), "Ninsianna Update" (1980), and "Section II, The Artificial Insertion" (1980). In 1994 a summary of this analysis was presented at the "Kronia Conference" in Portland, Oregon.

[\[return to text\]](#)

Note 5 --

"When the family of the Babylonian kings died out, after 8 years of no kings,

Esarhaddon the king of Assyria conquered them and held that kingdom for 13 years. (Ptolemy's, Can. Reg.) It appears Assaradinus is the same person as Esarhaddon. This is from the similarity in the names and by the word of the Holy Scripture. It intimates that he was king both of Assyria and Babylon at the same time. 2Ki 17:24 19:37"

-- James Ussher, *The Annals of The World* (1650)

Kingship in antiquity was not assumed arbitrarily. Kings were appointed by the Gods, and kingship stayed in a family. This was recognized even by the conquerors of a nation.

[\[return to text\]](#)

Note 6 --

Assurbanipal is the third son of Esarhaddon, and is installed as king of Assyria apparently through the intrigues of his grandmother (who was Sennacherib's surviving wife, a Canaanite princess), and selected as the most able of the three sons of Esarhaddon.

By a proclamation in 672 BC, his father Esarhaddon, had ordered that on his death Assurbanipal should be crowned king of Assyria, and Shamash-shum-ukin as king of Babylon. Thus the (older) crown prince (installed in Babylon) was skipped over for kingship of Assyria. He, of course, revolts at a later date.

Under Persian rule, after another revolt in Babylon, Xerxes melted down the statue of Marduk in 482 BC. When the historian Herodotus arrived in Babylon a generation later, he climbs the 360 stairs of the ziggurat to find the chapel at the top empty.

[\[return to text\]](#)

Note 7 --

The suggestions of a world-view for the Mesopotamians is developed in the chapter "Language and Causality," under a discussion of languages and their influence on the conceptual point of view of reality for a people.

[\[return to text\]](#)

Note 8 --

The story of the Assyrians and Babylon recounted here is an abbreviated version. For greater detail see the last chapter of H. W. F. Saggs, *Babylonians* (2000). A time-line of secular and celestial events in the 7th century BC follows.

time-line of secular and celestial events

Data below are in Eastern Mediterranean chronology, and not corrected to astronomical dates. Thus 680 BC (below) will later be shown as 685 "BC" -- actually meaning -685.

tablet year nny events (nny = no new year)

-----	----	----	-----
	689		Babylon destroyed
	688	1	New Year not celebrated (see 'nny' series at left)
.....	first series	of the Venus Tablet data ...	
1	687	2	(Earth's eccentricity at 0.10)
2	686	3	(Earth shock recorded, Sennacherib at Jerusalem)
3	685	4	
4	684	5	
5	683	6	
6	682	7	
7	681	8	Sennacherib assassinated (8th year of no temple)
8	680	9	Sennacherib's son Esarhaddon becomes king of Assyria. Venus's disappearance in the east delayed one month Babylon rebuilt -- "Year of the Golden Throne"
.....	second series	of the Venus Tablet data ...	
9	679	10	(Earth's eccentricity at 0.10, but aphelion moved)
10	678	11	
11	677	12	Esarhaddon's son Shamash-shum-ukin moves to Babylon
12	676	13	
13	675	14	
14	674	15	
15	673	16	
16	672	17	
17	671	18	
18	670	19	
.....	third series	of the Venus Tablet data ...	
19	669	20	Esardahhon dies (Earth's eccentricity at 0.0+)
20	668	21	Esardahhon's son Shamash-shum-ukin becomes King of Babylon; Marduk returned to the temple. Year 21 without a New Year celebration
21	667		New Year celebrated again
.....	end of the Venus Tablet data ...		

Note that the year of the Earth shock, 686 BC, falls in this period, but is not an instrumental part of the calculation.

There are a number of discrepant dates, being off by one year, which may follow from the fact that Assyrian years were counted from the spring equinox (rather than January 1), and the fact that I use astronomical years as calendar years without numeric conversion. This may also suggest that the eruption of Venus may have happened directly before the rebuilding of the temple compounds. Celestial data for 680 BC shows up correctly as ephemeris information for 685 BC, Julian, however. This corrects for the four-year difference between Eastern Mediterranean chronology and actual years (the error of four years by Dionysius Exiguus), and the fact that I seem to be off by a year in the above chart. (There is no year zero in these tallies.)

[\[return to text\]](#)

Note 9 --

Except for the records detailed in the *Chilam Balam*, there are few sensible Mesoamerican details about Venus (Quetzalcoatl) in 685 BC, except notions that he set himself on fire and disappeared across the ocean on a raft of snakes. I could suggest that "the ocean" is the Absu here and the raft of snakes are seen near the equinox, similar to Scylla of the Odyssey -- except that the imagery is 1700 years late. It was more important to the people of Central America to have received the promise made by Quetzalcoatl to return and set things right. It was another salvation religion introduced to the world.

"An outstanding problem with the analysis is the eastern disappearance [of Venus] on the twenty-fifth day of the twelfth month of the eighth year. Our model requires that the

invisibility ought to have begun at least a month earlier than that."

-- Rose and Vaughan

The month delay (before the period of the "Golden Throne") might suggest that Venus had changed the shape of its orbit, perhaps moving its perihelion to a different location along its orbit, although Rose and Vaughan claim that the orbit of Venus did not change during this period. Rose and Vaughan suggest that in this case the *Venus Tablets of Ammizaduga* might have misspelled the name of a month.

[\[return to text\]](#)

Note 10 --

Augustine quotes a lost document by the Roman Varro of the first century BC, but places the event at the time of the Exodus.

Homer makes no mention of Phaethon (except as an epithet for Helios), unless we were to understand the pouting of Achilles represents the unwillingness of Jupiter to act in response to the destructiveness of Mars (Ares) for 120 years.

Hesiod mentions Dawn as the parent of Phaethon. Apollodorus does the same in the second century AD. A document attributed to Hyginus in the same century also mentions the ride. In many instances Phaethon is equated with Saturn and, more often, with Jupiter.

Marinus van der Sluijs has compiled a collection of information from classical authors of the Mediterranean, involving the Great Year, Phaethon (which remains unidentified), comets, and planetary conjunctions in "Phaethon and the Great Year" in Apeiron (2006). All of the information backs up the narrative presented in this text. According to vd Sluijs, what is missing in late antiquity is any clear identification of the planets. I don't have that sense.

The retelling of the Phaethon legend by Ovid (43 BC -- AD 17) is correct in detail for the nova event of Venus in 685 BC, except for the timing. Ovid has the whole of the ride of Phaethon happen in one day. But see the "Star Wars" chapter for more; this describes the movement of Venus and Mercury through the skies in accurate detail.

When Ovid and other Roman writers describe, "the Earth was burned up," as a detail of the retelling of the legend of Phaethon, they do so correctly. Other exploding blazings in the sky have sent "the fire of Heaven" (Ignis Coelis) to regions of Earth, as late as AD 900.

The "Great Chicago Fire" of AD 1871 has been attributed to Ignis Coelis. Large forest fires happened in Northeastern Wisconsin near Green Bay (the "Great Peshtigo Fire") and in Upper Michigan on the same date and on the same evening as the Chicago fire.

More recently, the patchwork of simultaneous fires in Southern California in October 2007,

looks, from maps of the affected areas, to be distributed in a fashion very similar to the Great Chicago Fire of AD 1871 -- locations separated by many miles, but all along a north-south line.

Of course a long rainless season and dry tinder is a prerequisite. But the lightning strikes, which are thought to cause the ignition, were absent. Most of the 170 fires started up simultaneously on July 15. Arson has been suggested, but that would involve an amazing coordination of efforts and fails to even suggest a reason for the efforts. Similar north-south directed strings of fires happened in Greece during 2007 (June 28 and July 15) and Croatia (July 27).

[\[return to text\]](#)

Note 11 --

The *Zend-Avesta* are the sacred books of the Parsis of India, the remnants of the scriptures of Zoroastrianism (Mazdaism) at an earlier time in Persia. In 500 BC Herodotus makes indirect references to Zoroastrianism in his discussion of Persian religion.

The quotations are from the translation by James Darmesteter in 1880, and are abridged. The translator (or a later editor) notes, "Tishtrya is the angel of the star Sirius." This is a fictional association established long ago in Mesopotamia and Egypt. Each person had a star associated with their "spirit." Other quotations make clear that we are not talking about Sirius, as, for example:

"We sacrifice unto Tishtrya, the bright and glorious star, that afflicts the Pairikas, that vexes the Pairikas, who, in the shape of worm-stars, fly between the earth and the heavens, in the sea Vouru-Kasha, the powerful sea, the large-sized, deep sea of salt waters. He goes to its lake in the shape of a horse, in a holy shape; and down there he makes the waters boil over, and the winds flow above powerfully all around."

The sea here is in the cloud-bearing sky. James Darmesteter, in the introduction, writes:

"The scene of the fight is the sea Vouru-kasha, a sea from which all the waters on the earth fall down with the winds and the clouds; in other words, they fight in the sea above, in the atmospheric field of battle."

The Vouru-Kasha is in effect the Absu, imported into the hymn to Tishtrya from much older sources, not untypical of the remainder of the *Zend-Avesta*, where older "mythological" elements are incorporated in the text. Internal literary consideration would suggest that the actual written texts date from the Sassanian period of Persia, AD 200 to AD 600.

"He makes the waters boil over," is generally attributed to the star Sirius, when it would be seen at the east horizon where its path merged with the last remaining ring of the Absu. The image of the planet would flicker. This would also be true of any bright planet found on the

ecliptic at the point where it crossed the remaining ring below the equatorial. This is thus a likely condition for planets in June or July, since this time of the year represents the maximum displacement of the ecliptic throughout the night, and planets will very likely be traveling through the last ring below the equatorial for some portion of the night.

[\[return to text\]](#)

Note 12 --

Velikovsky uses these descriptions as suggestions for the events of 1500 BC, but the composition of the Zoroastrian *Avesta* dates from well after 600 BC. He notes that editors other than James Darmesteter have described the hymn as a battle of Venus and the stars against the planets. I did not read that into the hymn, but it would be of revealing significance, since indeed the stars end up in complete disarray.

I should clear up some other "strange celestial events" which have come to haunt Velikovskian discussions. Astronomical information compiled by Huang Sheng (AD 1146 to 1194) includes the statement that "Once T'ai-P'ai [Venus] suddenly ran into Lang Hsing [Sirius], though it is more than 40 degrees south of the Yellow Road." But to have Venus move this far off the ecliptic (the Yellow Road), and then return, is physically impossible and represents a complete misunderstanding. The text, as it has come down to us, has to represent an emendation of earlier sources. Most likely the phrase "ran into" is an interpretation of "at the same time," not "at the same place." It is amazing that this text was copied without thought from one author to another in antiquity, including the detail of the 40 degrees between Sirius and the ecliptic (the actual separation is 37 degrees in latitude).

The "astounding event" in question is the simultaneous heliacal setting of Venus and the heliacal rising of Sirius in AD 350 (about July 10 or so) when they are only 30 degrees apart at the horizon, and after a day or so could be mistaken for each other. This is a very rare event (to be so close together just as the Sun rises), which only happens at 730-year intervals. Since this is a heliacal rising, Sirius had not been seen for months, while Venus had been moving closer to the east horizon, day by day. Just as Venus disappears behind the Sun, Sirius first shows as rising heliacally. Venus is at this point occluded by the rising Sun, and thus Sirius might easily have been misidentified for Venus, making it look as if Venus suddenly jumped off the zodiac. It happened again in about AD 1080, a century before the time of Huang Sheng's compilation, but this event went unrecorded. Sirius is the brightest star in the sky and of about the same magnitude as Venus.

Jan Sammer writes of the earlier notice of the same event,

"The same ancient tradition was [also] referred to by the early eighth-century AD Chinese astronomer Y-hang. As told by Gaubil, Y-hang wrote that 'in the time of Tsin one saw the star Sirius eclipsed by the planet Venus.'"

This is the event noted above which happened in AD 350. The Tsin dynasty dates from AD

265 to AD 420.

[\[return to text\]](#)

Note 13 --

Hercules sets himself on fire to escape a skin disease brought on by donning a poisoned garment. Mars was seen at close range through portions of the 8th and 7th century BC, and before the eruption of Venus, but did not come close to Earth again thereafter. The sightings were close enough that the Martian landscape is seemingly described by Hesiod in his composition *The Shield of Hercules*. The sight of the pockmarked and scarred lower hemisphere might have been evidence enough that the planet was suffering from some terrible disease. The later nova event of Venus constituted his funeral pyre.

[Image: Mars in a dust storm, September 2001, after NASA.]

The garment might also have been a global dust storm, which still obscures Mars today after it passes Earth and is subjected to increased plasma impinging on its surface from Earth's plasmasphere tail. (Last noted in AD 2001.)

[\[return to text\]](#)

Note 14 --

M. A. van der Sluijs, in "On the Wings of Love," *Journal of Ancient Near Eastern Religions* (2008), makes the case that the Phaethon of Hesiod is the same as Phaethon of Ovid and Nonnos. See <http://www.mythopedia.info/two-Phaethons-JANER.pdf>. Quoting an absolutely minimal description from Hesiod:

"And to Cephalus she [Eos] bare a splendid son, strong Phaethon, a man like the gods, whom, when he was a young boy in the tender flower of glorious youth with childish

thoughts, laughter-loving Aphrodite seized and caught up and made a keeper of her shrine by night, a divine spirit."

"She" here is Eos, dawn. As I have pointed out in the text, the electric impact between Earth and Mercury a year earlier (686 BC) reduced Mercury's orbit to fall close to the Sun, so that indeed he would show as the "Morning Star." Thus Mercury at this time had to be reconciled as being "new," so that calling Mercury or Phaethon "the child of Dawn" is perhaps appropriate, since Mercury would only show at dawn, briefly. Only the reference to giving birth keeps this mention from being totally enigmatic, for otherwise we would have to assume that Mercury had been in the position of only showing briefly at dawn for eons.

Van der Sluijs follows up on the earlier quotation from Hesiod with a quotation from Hyginus, 750 years later, in the second century AD:

... in his book on astronomy, alluded to what is evidently the same story concerning the anonymous Aurorae et Cephalii filium, "son of Aurora and Cephalus", whose beauty rivaled that of Aphrodite:

"Some have said it represents the son of Aurora [dawn] and Cephalus [another hero kidnapped by Dawn], who surpassed many in beauty, so that he even vied with Venus."

Vd Sluijs elucidates "it" as "the star of Venus," but Hyginus had already identified "it" as Saturn in his text in the then current tradition which assigned "Phaethon" to Saturn or Jupiter. "It" cannot simultaneously "be Venus" and "vie with Venus." But vd Sluijs bolsters the tradition of an abducted Phaethon with other quotes from antiquity.

Knowing the placement of the planets in the sky for the years of 686 BC (after March) and 685 BC, all the various attempts at anthropomorphized rationalizations in antiquity start to make sense. It is still somewhat disconcerting to realize that Hesiod, who most likely witnessed the events of 686 and 685 BC, did not make more of it. This suggests that perhaps the mythology of the misguided "chariot of the Sun" and the death by a lightning bolt may have had its source in Asia Minor, the same region which yielded a number of religions based on the death of a Son of God, rather than Greece.

[\[return to text\]](#)

Note 15 --

James Darmesteter, in his introduction to the translation of the *Zend-Avesta*, also makes note of the lightning bolt in Zoroastrian and Vedic literature:

"Sauru, which in our texts is only the proper name of a demon, was probably identical in meaning, as he is in name, with the Vedic 'S'aru,' 'the arrow,' a personification of the arrow of death as a godlike being."

"The same idea seems to be conveyed by Ishus, 'the self-moving arrow,' a designation to be accounted for by the fact that Saru, in India, before becoming the arrow of death, was the arrow of lightning with which the god killed his foe."

Neither the *Popol Vuh* nor the *Chilam Balam* has reference to the plasmoid from Jupiter as events, but only as objects. In the *Popol Vuh* a "bundle" is identified as in the possession of the Quiche tribe by the time they receive their tribal Gods. Considering the 120-year period when the Earth was constantly subjected to lightning strikes from Mars, perhaps it could be understood that a lightning bolt from another planet might have been accepted as matter of fact. But it seems unlikely.

[\[return to text\]](#)

Note 16 --

I am basing this on timing developed in the chapters "The Books of the Chilam Balam" and "Olmec Alignments," that is, that it took 12 days to travel 484 million miles. Thus the bolt was only seen in the daytime sky as it passed Earth for two and a half days. During two half-day periods of this time the Pacific Ocean faced the traveling plasmoid. During the other times first America, then Asia, and then Europe, in that order, saw the shape in the sky as the bolt passed by. Asia and Europe only saw the bolt as it was approaching and again after it had passed by Earth.

[\[return to text\]](#)

Note 17 --

The understanding of Olmec iconography is completely submerged under ideas of depicting ears of maize as sacred aspects in a completely unknown philosophy, religion, and social structure of the Olmecs and the people of the Valley of Mexico. See, for example, Karl Taube, in *Olmec Art at Dumbarton Oaks* (2004). Certainly the Olmecs would see the metaphorical connection between flower-shaped plasma expulsions and ears of maize. The use of a tri-lobed headdress and depictions of ears of maize may have preceded 685 BC. Later Maya iconography clearly depicts the maize iconography. It is curious, however, that sprouted and ripening maize does not look like that.

What we think we know about the Olmecs is without exception completely derived by analogy from the structure of our own society. Taube suggests that it is the export of "rich agricultural abilities" and a "symbolism of agricultural fertility and wealth" which provided the exchange basis for raw materials such as jade, as if trading technology for materials. I would suggest that their main export was a religion with a claim of control over the sun and the rain.

For the jester-god see the summary of archaeological sources and iconography bearing on this in a paper by Virginia M. Fields, "The Iconographic Heritage of the Maya Jester God" (Los Angeles County Museum of Art, 1991).

[\[return to text\]](#)

Note 18 --

Almost universally all the retellings of the legend of Phaethon, from 500 BC to AD 500, add the curious detail that as Phaethon dies he falls into a celestial river "Eridanus" (a constellation), or the river Po in northern Italy (also known as Eridanus), but located northwest from Greece. His three, seven, or nine sisters, who mourn his death, are turned into poplar trees along the river, and their tears drop as amber beads into the water. The poplar is a very slim tall tree of the Mediterranean region, and perhaps apt as a representation of plasma plumes.

Amber washes up at the shores of the Baltic. The change in the axis of the Earth in 685 BC moved the Arctic Circle six and a half degrees of latitude further north, perhaps bringing the region of the Baltic into the European trade circuit. The amber beads have their source in a play on words, but also accurately reflect their source in trade from the Baltic. (Amber is found in the Po region of northern Italy also.)

[\[return to text\]](#)

Note 19 --

Chaldea was originally a nation from Southern Mesopotamia or Northern Arabia which came to rule at Babylon after 625 BC. Bishop Ussher records for 261 BC:

"Gerosus (Pliny l. 17. c. 56.) published the observations of the Celestial Motions among the Babylonians for a period of 480 years. This is the number of years from the beginning of the Epoch of Nabonassar's account [747 BC] as other learned men understand this."

Others have pointed out that there are no sensible records for the period of approximately 750 BC to 700 BC, with the exception of the *Venus Tablets of Ammizaduga*. What we have today is data only from after 650 BC.

[\[return to text\]](#)

Note 20 --

From the data of the eccentricities, Rose and Vaughan come to the conclusion that the ratio of the synodic periods of Earth and Venus was 1.63. (A synodic period is the time a planet takes to complete one orbit as seen from Earth.) This is close to today's ratio of 1.625.

"From the first, humanity had to be religious. It is still so.
Further, it will be religious so long as it will exist.
Religion is ultimately hope, and humans live on hope."
-- Alfred de Grazia *The Divine Succession* (1983)

Dating the Events of 685 BC

This chapter deals with the world following 120 years of electric contacts between Earth and Mars, from 806 BC to 687 BC, and the subsequent blazing of Venus and Mercury in 685 BC. This is an era which will see the start of history, science, and philosophy, and the genesis of contemporary religions. All four are the direct result of the events of 685 BC. The quieting of the skies after 685 BC affected how humans saw the world, and we see immediate attempts to reach a new understanding, a science not based on the willful and arbitrary actions of the Gods. At the same time, a much larger religious conceptualization comes forward, based on a power beyond the observable Universe. But first, dates for the year 685 BC.

I'll briefly describe how the four dates of the events of the year 685 BC were found. The dates can all be derived from the Maya *Chilam Balam*, verified from Mesoamerican site alignments, and partially verified from information from the Eastern Mediterranean region.
[\[note 1\]](#)

The dates, on the Gregorian calendar and all in the astronomical year 685 BC, are as follows:

- Venus and Mercury start to blaze, June 15
- Jupiter develops a coma, July 9
- Jupiter releases a plasmoid bolt, July 14
- Jupiter's plasmoids lands at the Sun, July 25

In the later chapter "Olmec Alignments," I have determined the three previous dates when the world was destroyed and recreated (in 2349 BC, 1492 BC, and 747 BC), from site alignments in Veracruz and the Valley of Mexico (alignments of the sites to a setting sun at mountains or volcanoes). For the 13 sites which were considered, 20 alignments can be assigned to September 8, 2349 BC (or the later equivalent for the setting of the Pleiades), 16 alignments can be assigned to April 19, 1492 BC, and 10 alignments can be assigned to February 28, 747 BC. This is an astounding series of coincidences -- especially since these were distributed over only 13 sites.

Thus when I started to find additional alignments to July 9 (4 or 5 instances), July 14 (5 instances), and July 25 (7 or 8 instances), they could not be ignored. Additionally, August 12 started to show up. August 12th or 13th was a retrocalculated date for the "second creation," probably first used at La Venta, and then by the very influential city of Teotihuacan, where it was achieved with an alignment of the primary axis of the site. There may be other alignments like that, but I do not have site plans for other sites. The additional alignments, by the way, occur at sites dating in their construction to after 600 BC. Details below.

The following lists the dates in reverse order, for once the concluding date is found, the other dates can be found in reference to that.

... ending date, July 25th

The first inkling that July 25th may have been an important date in Mesoamerica was the fact that the Maya celebrated the following day as "new year's day" at the time of the Spanish invasion. The date is mentioned by bishop Landa, and was apparently set at the Maya site of Edzna in the Eastern Yucatan, where a vertical gnomon has been found, set to show the overhead passage of the Sun on July 25th. Edzna is at the same latitude as the city of Teotihuacan in the Valley of Mexico, where one of the site alignments (to a mountain) is also for July 25th. The next day, July 26th, was new year's day and the start of a seasonal agricultural period.

The importance of the date of July 25th can also be suggested from the fact that Book 10 of the *Chilam Balam* makes only one error in the recollection of the 7000-year history of celestial events, and that is to force the assignment of July 25th to the event of 2349 BC (which we know as the flood of Noah), by reassigning the event to an incorrect year (actually to an incorrect Katun and Tun). The "flood" of 2349 BC, known to the Maya as the "third creation," was very important, as can be shown from the continued iconographic references

in sculptures 3000 years later. Having experienced the end of an era on July 25th, 685 BC, it became necessary to prove that all previous eras had also ended on July 25th. (More on this particular quirk in the chapters "The Books of the Chilam Balam" and "The Day of Kan.")

If July 25th is accepted as the day that the plasmoid from Jupiter landed at the Sun, and brought quiet to Venus and Mercury, ending a 120-year period of high planetary activity, then other dates and time spans will segue easily to this date in 685 BC.

... start of the eruption of Venus, June 15th

The starting date of the nova event of Venus in 685 BC can be found by collation of some disparate data. My first clue was a comment by Dennis Tedlock, translator of the Quiche Maya *Popol Vuh*. He commented on a passage where the hero twins of the *Popol Vuh*, Hunahpu and Xbalanque, willingly jump into the oven of the lords of Xibalba (the underworld). In the *Popol Vuh* the lords attempt to trick the twins into jumping into an oven. The twins see through the trick, and respond as follows:

"You'll never put that one over on us. Don't we know what our death is, you lords? Watch!" they said, then they faced each other. They grabbed each other by the hands and went head first into the oven.

Little did the lords of Xibalba know that in sacrificing themselves, the twins were destined to "become" the Sun and the Moon. Mesoamerica certainly understood that both the Sun and the Moon had made their first appearances in the remote past, the Sun in 4077 BC, the Moon in 2349 BC. But connecting an event of 685 BC to events thousands of years earlier was not a problem to the Maya, especially in a popular narrative which had already existed since the Classical period (AD 400 to AD 900), as can be ascertained from depictions on vases from this period. [\[note 2\]](#)

In the *Popol Vuh* the twins Hunahpu and Xbalanque are understood to be Venus and Mars. This much is certain from the story of their birth, and can be collaborated from comments in the *Chilam Balam*. But this is not correct for the last instance. In actuality the two planets which were seen in flames in 685 BC were Venus and Mercury. Hunahpu definitely is Venus. As Tedlock notes, he is named after the first day of the five periodic cycles of Venus as Morning star and Evening star. Xbalanque, on the other hand, is not as easily identified. His name could be translated as "little jaguar of the night" where "X" is a diminutive. Xbalanque is always "little," whereas the term "little" is only applied to Hunahpu in a very few instances. In the *Popol Vuh*, Hunahpu always acts in the daytime, Xbalanque acts at night. This would seem to correctly reflect on what side of the Earth Mars (and in the last instance, Venus) and Mercury primarily acted during the 60-year period after 747 BC.

In the last instance, when two planets go up in flames, the two planets are Venus and Mercury. Venus is large, and seen as large, especially with a coma, whereas Mercury is

definitely small. Mercury had lost most of its atmosphere two years earlier, and looked no larger than it is today, although after June 15th it was blazing like a sun.

I am making this identification, because the confusion of the planets existed already in antiquity. For example, in the Eastern Mediterranean region it was assumed (in some retellings) that the eruption of 685 BC only involved Venus. Mercury travels so close to the Sun that it could easily be confused with the Sun if it (or both) were seen blazing in the sky, and Mercury normally could not be located in the skies during the day, unlike Venus, which was visible day or night because of its coma and tail. Mars was also in the skies in 685 BC, close to the Sun but behind it.

Identifying Xbalanque as Mercury allows following up on a comment by Tedlock which comes some pages later after the following text in the *Popol Vuh* which reads:

And then the boys ascended this way [leaving Xibalba], here into the middle of the light [that is, this world], and the sun belongs to one and the moon to the other.

Tedlock writes in his notes:

It is not stated literally that they became the sun and moon. ... The nature of Xbalanque's lunar role is foretold by the fact that he is face-to-face with Hunahpu when they burn together, this being the position of the moon when it is full.

The comment is revealing, but the statement is wrong. This imposes our knowledge of how the Moon and Sun are related, and the cause for a full Moon. For a people to whom the Earth was flat, only a new Moon would fulfill the condition of the Sun and Moon facing each other. They had to be in the sky at the same time, and close together. In fact, looking at a graphical ephemeris for July 25, 685 BC (the ending date), Mercury is seen next to the Sun, and Venus next to the new Moon.

I thus started to look at new Moon dates in the year 685 BC. From about the time of the equinox, when Venus might have first returned to view from behind the Sun, through the beginning of July, before the concluding day of the nova event, there are five new Moons. In each of these instances the Moon would be very near the Sun. The condition I was looking for was the simultaneous close proximity of Venus and Mercury in the sky.

The following are the new Moon dates, and the location of the planets with respect to the Sun, shown in Right Ascension (hours and minutes of left-right location): A minute is 0.25 degrees. I have only listed the two instances where Venus and Mercury are close together, May 23 and June 22 (Julian).

**From east to west in the sky at noon sidereal time,
Mexico City. Right Ascension in hours:minutes.
Dates shown as Julian.**

May 23 --

Mercury, Venus, Sun, Moon, Mars

4:50, 4:40, 3:25, 3:23, 3:05

Mercury and Venus are close together in Gemini.

The Sun and Moon are close together at the east end of Taurus.

June 22 --

Venus, Mercury, Moon, Sun, Mars

7:20, 7:08, 5:15, 5:26, 4:29

Mercury and Venus are close together in Leo.

The Sun and Moon are close together between Cancer and Gemini.

The above dates of May 23 and June 22 qualify. In both instances Venus and Mercury are grouped close together, one almost above the other, but slightly displaced. In effect Xbalanque and Hunahpu are facing each other, almost holding hands. The Sun and Moon are nearby and in an almost identical position with respect to each other. The point of this exercise is based on the conviction that the Olmecs would have seen these conditions, and furthermore recorded them.

I picked the June date as most likely. June 22 Julian is June 15 Gregorian. The choice of June 15 was made on the basis of information from the other end of the world, from the "Tishtar Yasht" hymn to Venus, of the *Zend-Avesta*. Tishtrya (Venus) battles demons in the sea (sky) for 34 days before victory is achieved. I have noted the details in the previous chapter. Thirty-four days fits the span of time from June 15 to July 25 (Gregorian), with a few days left over, which may also be accounted for in the hymn, but not clearly.

But much more convincing is the description of the blazing of Venus in 685 BC recorded in the *Sibylline Oracle Books*, composed at a much later date in Alexandria, Egypt. The *Sibylline Oracle Books* clearly places Venus in Leo at the start of the event. In fact, as others have noted, Venus riding on the back of a lion (the constellation Leo) was regarded as a symbol of disaster in the Eastern Mediterranean.

Does this date, June 15, show up in Mesoamerican site alignments? No. I almost wrote, "of course not." It does not show up because it is the start of an event; the structure of Mesoamerican languages recognize only the completion of events, and pays scant attention to beginnings.

However, the *Chilam Balam* records a period of time when "it came about that the sun in Katun 3-Ahau was moved from its place for three months." The complete period is noted because it was a celestial disaster of immense scope. Katun 3-Ahau includes the year 685 BC. The three months (of 20 days) are counted inclusively, as are all other intervals of time mentioned in Book 10 of the *Chilam Balam*. So the actual period is two Tzolkin Uinal months. The interval of 40 days (two 20-day months) exactly spans June 15th to July 25th.

... the release of the plasmoid bolt, July 14

This date is based on an interval of 12 days which was put to use in a reconstruction of Monte Alban in 275 BC (detailed in a later chapter), the fact that July 14th is used by five sites as an alignment, and the suggestion of possible selection of the "day of Kan" associated with the end of an era -- the delivery of the plasmoid on July 25th. Additional nuances with respect to Mesoamerican attempts to forge a science from the numerology of the Tzolkin calendar, including the elusive search for the "day of Kan," are discussed in a later chapter. July 14th also represents a reasonable interval of time for a plasmoid from Jupiter to travel the 480 million miles (773 million km) to the Sun. I develop the reasoning for this date in the chapter "The Day of Kan." Since it would take a considerable amount of text to detail all this here, I will have to leave off at this point in the retelling.

... Jupiter develops a coma, July 9

This date is based solely on the fact that it first shows up at Tres Zapotes, recurs 4 times elsewhere, and represents an adequate interval for Jupiter to have been seen with overhead plasma plumes and a lower bifurcated or trifurcated body -- so that these shapes would enter Olmec iconography. This date is thus not well supported. Although the site alignments associated with this date are within two degrees of solstice alignments, it is unlikely that these represent a solstice, despite the fact that both Vincent Malmstrom and Anthony Aveni delight in assigning Mesoamerican site alignments to Summer solstices. The later Maya (and Aztecs) had no ceremonies or festivities associated with the solstices.

Selection of this date for a sunset alignment is somewhat problematic, for "beginnings" are seldom held as significant in the Mesoamerican worldview. What could make the date of July 9 significant is the consideration that the explosion of Jupiter into a coma was a return from the dead (and thus the conclusion of a "death" period) of what would have been, at the time, the primary God, in a manner similar to the return from the dead of Jupiter in 2349 BC. This previous event was certainly remembered, and had been recorded in graphic books. The iconography of the split mountain, the Absu at the autumnal equinox of 2349 BC with an emerging and resurrected God, continues well into the future. The ballcourt imagery is based on this also.

The primacy of a chief God passes to Quetzalcoatl or to the ball-playing twins of the *Popol Vuh* after 685 BC, however. I think we need to see the July 9th alignment as one of the religious interpretations of the events of 685 BC which did not take hold in any measure.

Hour of the Thunderbolt

Mesoamerica did not see the plasmoid hit the Sun, for it happened two hours after sunset in Mexico. In the Eastern Mediterranean the flash happened two or three hours before sunrise.

But in Australia it happened in full view an hour after sunrise in the morning.

The time of day can be found from an Australian Aborigine legend, called "Kirkin and Wyju," recorded by William Ramsay Smith in *Myths and Legends of the Australian Aborigines* (1930). It appears to be about Venus (Kirkin) and Jupiter (Wyju) in the winter (in the southern hemisphere) of 685 BC.

The story portrays Kirkin as very conceited and self-centered. He combs his long blond hair daily, facing the Sun, and tosses it over his head to the front at times in a vain display. (Blond hair occurs among the aborigines.) Wyju, on the other hand, is characterized as "a humble man, who did many wondrous acts." Part of the story tells of his rescue of a child who was swallowed by a God Snake. Wyju has to coax the snake into an upright position, for otherwise the local water supply would disappear. With the snake standing on the tip of its tail, Wyju sliced the snake open along its back to remove the swallowed child.

This will be recognized as an image of the polar plume, with the swallowed child as the ball plasmoid near the end. The timing is wrong, but for the sake of a moralizing story, that doesn't matter. There will be a later image of the polar plume in terms of a column of white smoke.

"The story of his wonderful deed reached even the conceited Kirkin, who became very jealous, and decided that if Wyju should come within the bounds of his hunting ground he would endeavour to slay him."

Kirkin, in fact, invites Wyju to be his guest. During the evening meal Kirkin suggests they go hunting the next day for Wallows --rat-kangaroos While Wyju sleeps, Kirkin goes to a nearby Wallow nesting ground and places pointed sticks in the ground around a dead Wallow, with a hidden string tied to the grass and leading away from the location. Kirkin recommends to Wyju:

"To procure this most coveted prey no spear, boomerang, or nulla-nulla is required. You simply walk cautiously into the nesting-ground, and when you see the grass moving you know that beneath it lies the wallow, and with a mighty leap into the air straight above the prey you come down and let your feet land right upon it."

The next day, during the hunt, Wyju does exactly that.

"Wyju jumped with all his might, and came down with both his feet upon the sharp spikes, which pierced them deeply."

Wyju faints in pain, and when he comes to, Kirkin tells him:

"Oh my friend, when you walk upon your feet please don't forget to look me up. The sign by which you will find me is a white smoke column that rises on a still, clear day."

Kirkin leaves, leaving Wyju to suffer and bleed.

"From new moon until next new moon did Wyju, overcome with pain and suffering, weep and cry unto the All Father Spirit."

He requests the Winjarning brothers be sent. They appear at the second new moon and heal his feet. Note the *new moon* dates. You will recognize the period of two new moons from the Mesoamerican *Popol Vuh* narrative.

"Wyju went in haste far away into the northern land, and saw a white smoke column rising straight into the clear blue sky. [He walked until] ... he came within sight of Kirkin, who was walking round and round the fire."

After sunrise the next day, armed with a warrior's boomerang, Wyju closes in on Kirkin, who is facing east.

"He raised his weapon, and with a mighty stroke severed the head with the golden hair from the trunk. He then committed Kirkin's body to a fire. The spirit of Kirkin rose out of the flame and entered the body of a small hawk-like bird."

I was not entirely convinced until I ran into Jupiter suffering from the spikes in his feet from one new moon to the next new moon, and then a few additional days to hunt down Venus. That matches my deduced timetable, which goes from one new moon (June 15, Gregorian) to the next (July 14, Gregorian) plus 11 more days.

The spikes in Jupiter's feet may be the "long fire-flames [which] rebelled against the Sun," although related by the *Sibylline Star Wars* text to Mercury as well as Venus. And the blood: Jupiter's plasmasphere would have been red in color, as it had in 2349 BC. When the Olmecs start to construct pyramids, they are called "red mountains," after the image of Jupiter in 685 BC.

The Winjarning brothers seem to be the Australian version of the various celestial twins and brothers of Greece, Italy, and Mesoamerica: the Dioscuri, Romulus and Remus, Apollo and Heracles, and Hunahpu and Xbalanque of the *Popol Vuh*. Wow! That places the legend in the era of 800 through 685 BC. In Australia the boys are busy with "righting wrongs." The evil wrought in the northern hemisphere was absent south of the equator.

Wyju was initially a "half day's journey toward the rising Sun." That is about right; Jupiter stood a half-day toward the east in 685 BC.

The column of white smoke (!) from Kirkin's fire is the northern plasma plume, which would have shown up very soon after the Sun's nova event started. Even Nonnos recalled this 1100 years later. Kirkin has a fire going, which matches the various polar plasma plumes given out as "the fires of the four directions," as, for example, the four braziers of the Egyptians.

Kirkin's circumambulation is the apparent traversal of the north cardinal direction at about noon during most of the 40 days when Venus and Mercury appeared during daylight hours.

The bleeding of Wyju also shows up as the bright spikes shining through the last red ring of the equatorial rings. At the latitude of Perth (the likely location of the source for this tale) the Sun, Moon, Venus, Mercury are all below the equatorial at the second new Moon, and the condition of a backlighted red ring could have been seen (the red ring would not otherwise be seen in the daytime). By July 25 (Gregorian), when the skies were identical to today, Venus was probably within that band (ready to bleed), but not Jupiter. However, Jupiter's coma would be red.

In the Eastern Mediterranean the reverse was true. Jupiter may have been high enough at culmination (36 degrees at Cairo) to be behind the red ring (at 42 degrees). But it didn't matter. Jupiter had a large red coma and tail anyway. The Sun, Venus, and Mercury rode high above the equatorial, and were thus clear of the red ring.

After the spikes are removed, Wyju had traveled to the northern land where Kirkin normally resided -- "in haste." Was the plasmoid mistaken for Wyju? This actually happened in India and with Mazdaism -- the lightning bolt was a separate god. I think a substitution was made in Australia also. This allows Wyju to move "in haste" and to "sneak up" on Kirkin. As the plasmoid passed Earth it would have been seen moving rapidly. Then it slowed down visually, "sneaking up" on Kirkin.

The time of the decapitation is interesting; Wyju selects the "early morning hours of the rising Sun." If correct, this could serve as an anchor for other estimates.

In Western Australia near the end of July of 685 BC, Mercury rises at 6am, the sun rises about 7am, Venus rises two hours later at 9am. (The southern hemisphere is in winter.) Jupiter will not be in sight until late in the day, near 3pm. It is obvious that it is the plasmoid that needs to be watched, not the planet Jupiter.

If the blast at the Sun happened at 9am in Australia, it would be sensed as a flash at the horizon at 3am in the Eastern Mediterranean, which would be an hour before Mercury rose, and two hours before the Sun appeared (it is summer in the northern hemisphere). If the landing of the boomerang was seen an hour later in Australia, then the last travels of the plasmoid would still not likely to have been seen, since it was still an hour before sunrise in the Mediterranean. Mercury was above the horizon but became engulfed by the flash.

I had originally estimated the night as the time of the event for the Eastern Mediterranean, based on the fact that the Phaethon legend shows no clear idea of what entity in the sky was blasted by the thunderbolt. The estimates from Australia confirm the time.

Mesoamerica experienced the event at 9pm. The Sun and Venus had set. (Although in summer, as this location is near the tropics, the Sun had set at 7pm.) Mesoamerica also had

no idea of what object in the skies was hit. Only knowing that Mars was located just to the west of the Sun (and also below the horizon) would give a clue. Venus has just set at the western horizon a half hour earlier. It might have been obvious that Venus was not the target. The plasmoid had bypassed Venus. But Mars had been the culprit for 120 years.

In Mesoamerica the splashdown would show as a flash at the western horizon, where the Sun was below the horizon, having set about two hours earlier. If the blast had lasted longer than 9 hours (my estimate of the splashdown time at the Sun) it would still have been seen in the east in the morning hours. Thus so perhaps did Quetzalcoatl "go east and set himself on fire."

The rise of Venus after "8 days" (in Mesoamerican retellings) is equated to a canonical 8 days (for a westerly disappearance of Venus) because the skies were obscured for four days and this is what Venus was expected to do if it had been properly observed. The *Popol Vuh* mentions four days during which Hunahpu and Xbalanque appear as catfish ("seen in the river"). The catfish are likely smaller plasmoids from Jupiter which kept the turmoil at the Sun alive for these four days. This is similar to the sequence of plasmoids from Venus in 2349 BC: first a large thunderbolt, followed by lesser bolts in the following days.

I considered using a later hour (like 10am), for Wyju definitely sees Kirkin preening himself before launching the boomerang. Wyju comes up from behind, with Kirkin "facing the Sun." This is indeed the situation if Kirkin is Venus. Kirkin is east of the Sun, with its main large plasma tail facing away from the Sun, and Jupiter much further east, and thus sneaking up behind him, but Jupiter remained well below the horizon. It is the plasmoid itself, as the warrior's boomerang, which is seen.

If we wait for Jupiter to show above the southeast horizon, it will be after 2pm. That invalidates any estimated times for other longitudes. I'm inclined to move the character of Wyju from Jupiter to the thunderbolt on these last few days.

Burning Kirkin's body is interesting also. It recalls the Mesoamerican Quetzalcoatl. That would also make me believe that the decapitation probably started shortly after 9am. That way we have an all-day cremation event. It is over (most of it) in a few days. The fire is likely the north polar column in arc mode at its lower portion. The fire and the column would have remained in the same location in the sky. Also, the rising of the "spirit of Kirkin" duplicates the rising up of Venus as a star ("the Morning Star") as recorded in Mesoamerica.

Some things remain unresolved, but then, I think that everywhere in antiquity there was an immediate confusion of who was struck by lightning, and who was Phaethon. Hesiod's brief description, along with Hyginus (as pointed out by van der Sluijs), has Mercury as Phaethon, the same as Nonnos and Ovid. Others have Venus. The Eastern Mediterranean actually has it more correct than Mesoamerica, for by assigning Mercury to Phaethon, there was no need for a "rising into the sky" as Mesoamerica had. After the plasmoid was delivered Mercury was no longer seen in the day skies, and was seen only at night within a few degrees of the Sun at sunrise or sunset.

The flash most likely occluded the planets near the Sun, Mercury and Mars. Venus was some 35 degrees east (about 2.5 hours) of the Sun. It probably disappeared in the flash too. Strangely, the Sun was never the suspected target.

If the Eastern Mediterranean had seen the affair in the day sky, it would have been obvious that the plasmoid traveled past Venus, and not past the Sun, but the splashdown happened at night. That the boomerang came to a halt at the Sun should have been noted in Australia. But it was Venus which had lost its tail and coma.

Mercury was a peculiar object in that it only showed in the day skies for 40 days during this year, and then was never again seen rising that high. It had only taken up its regular station of the true morning and evening star in the previous year.

The last piece of discrepant information is the fact that Kirkin and Mercury, in addition to facing the Sun, were said to face east -- both on the last day. Only Mercury, west of the Sun could have been in a position to do both of these. Mercury was close to the Sun, about 15 degrees west.

Let me remind the reader that we are seeing all this in the southern hemisphere so that the location of the planets would seem to be reversed from what is seen in the northern hemisphere. The Sun rises in the east, but that is to the right when facing north and facing the equator, where the path of the Sun through the sky will be.

But now consider also the fact that between about July 8 and July 11 (Julian) Mercury moved from a position just east of the Sun to a location just west of the Sun. Since Mercury during these two days rode above the Sun (by 5 degrees), the effect would have been to see its plasma tail "hair" being tossed from his back over the top and to the front of his face. This matches the description of Kirkin:

"Every morning he would mount a high boulder and comb his hair. Then with both hands he would bring the golden shower from the back of his head to hang in front...."

Thus Kirkin in this last scene may be the planet Mercury. If so, then the delivery of the plasmoid at the Sun would have happened between 8am and 9am. In either case, 9am is probably a close approximation of the delivery time of the plasmoid.

The Start of History

What stands out in the period after about 600 BC, and increasingly over the following centuries, is a sudden intense interest in history, which shows up, not only in the Middle East, Greece, and Ptolemaic Alexandria, but also in China. Why this sudden flurry of research and speculation on events, and specifically only events of the recent past?

There had been over 600 years of a quiet sky, from 1440 BC to 800 BC. Then, within a span

of a little more than a hundred years, Venus, Mars, and Mercury closed in on the Earth (or seemed to). The length of the year changed, Mars repeatedly cruised very close to Earth (nine times) to cause massive interplanetary lighting strikes which traveled across wide areas and were accompanied by hurricanes of ground-up rock, burning trees, and flaming sand. Then, just as suddenly, after the nova event of Venus in 685 BC, which surpassed the Sun in brilliance and dropped fire from heaven over wide areas of the Earth, ending with a lightning bolt from Jupiter directed at the Sun, it all stopped.

During the 8th and 7th century BC, and periodically a hundred years earlier, endless wars had raged in the whole region of Mesopotamia and the Levant, mostly involving the states of Assyria and Babylonia feuding with encroaching tribes and kingdoms from the north. Starting in about 750 BC Assyria expanded to conquer all of Babylonia, Syria, the city-states along the Mediterranean coast, and eventually Egypt.

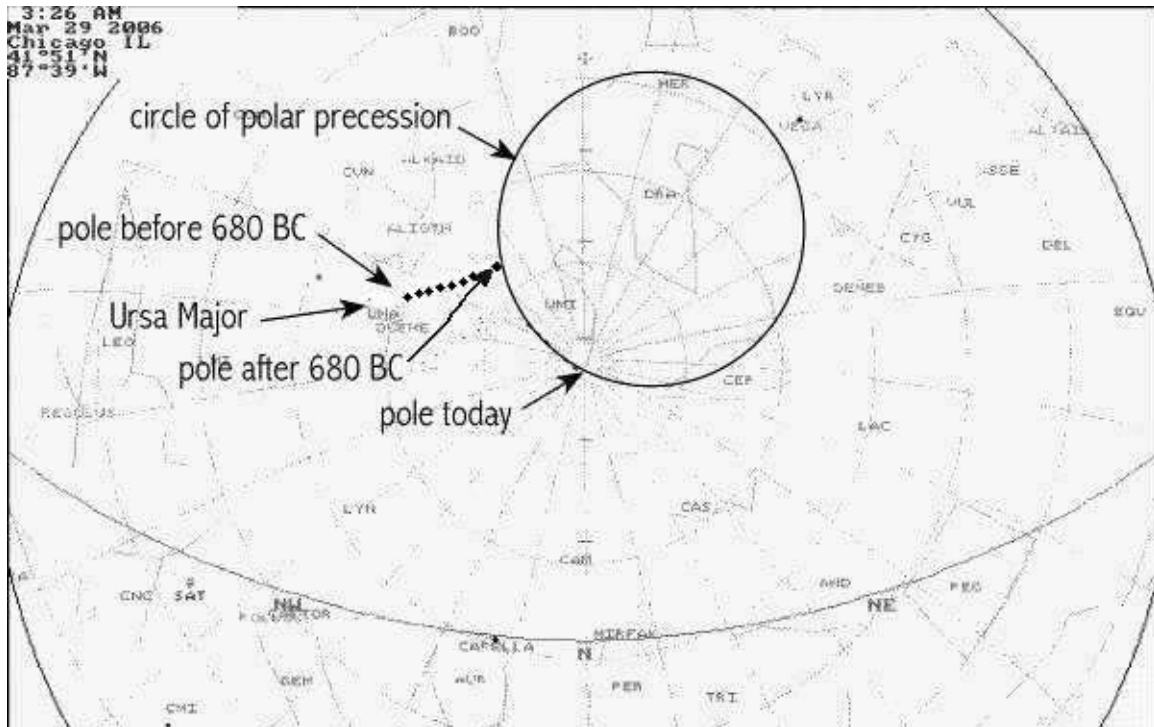

The physical and political changes required an explanation, and the first line of inquiry was to sort out the events. A change in perspective on the progress of time took place, which resulted in the increase of the number of chronicles and records. This is seen especially with the Assyrians, who start to record all their activities -- in effect, they start to write history (as do the Babylonians). The conditions of wars and the compilation of histories is the same in China.

This was followed soon by philosophical speculation, which we will eventually understand as the start of science. It should be recognized that the people of this era were technologically quite proficient. They could measure and map the stars and planets as well as the geography of the Earth, solve for the roots of quadratic equations, and undertake massive building and irrigation projects.

Bronze metallurgy was supplanted by the technology of iron after 800 BC. The smelting methods were apparently imported from regions north of the Caucasus. The Assyrians start producing iron weapons. They also adapt the horse to warfare, forging an effective and fast moving cavalry. The same Assyrians, by their own reports, model their warfare after 750 BC on the strikes of Mars and its hordes of companions, absolutely devastating their enemies with a cruelty unequalled in all previous history.

Historians after 600 BC will divide history into two parts, the era before 747 BC, and the era after 747 BC. The year 747 BC had seen a change in the length of the year, had thrown the lunar month out of sync with the year, and had initiated 60 years of geological and climatic disturbances. However, a more important date was 685 BC, when it all stopped.

A New Order of the Sky

[Image: The change in polar axis in 685 BC shown with a dotted-line. This is an approximation. The path of the polar precession describes a 30- to 32-degree circle about the location of the Sun's axis in space. Illustration by J. Cook.]

In the seventh century BC, as noted in the previous chapter, the spin axis of Earth (the polar axis) changed to point to a new location in the sky. Greek, Roman, Egyptian, Chinese, and Indian sources, without being specific about a date, all extrapolate to the 8th or 7th century BC as the date when the axis of the Earth changed from Ursa Major (the Big Bear) to a location closer to the Ursa Minor (the Little Bear). Today the axis is located at the tail of Ursa Minor. But both the new location and the actual cause for the change elude us. Probably the nova condition of the Sun caused the change of Earth's axis in 685 BC (not the thunderbolt from Jupiter in July of 685 BC).

Seneca and others claim that the Earth's axis of rotation, that is, the place in the dome of the stars to which it pointed (today at the star Polaris in Ursa Minor), was located in Ursa Major before the 7th century BC. Velikovsky quotes Seneca as, "And the Wain [Ursa Major], which has never bathed in the sea, shall be plunged beneath the all-engulfing waves." But this is hyperbole from the first-century AD play by Seneca, *Thyestes*. The Wain did not plunge below the waves of the Mediterranean sea at the latitude of Rome (42 degrees north) before or after the change in the sky. It still does not do so today. The tail started to just touch the ocean (the north horizon) after AD 200 as seen from the latitude of Alexandria in Egypt. All the rest of Seneca's description is just to make drama of a transformed sky. However, it is the use of a "changed sky" as a metaphor in his play which speaks to the fact that the changes were common knowledge. [\[note 3\]](#)

There are many other references in Roman, Greek, and Indian sources which note that the Earth's rotational axis had at one time been located in Ursa Major. There is even an old reference among the Pyramid texts, "the king looks among the stars of The Wain, to determine true north." [\[note 4\]](#)

The spin axis (polar axis) of the Earth points today to the star Polaris, at the end of the handle of the Little Dipper, the constellation Ursa Minor. Over the course of time the location where the axis intersects the dome of the stars is understood to move slowly on a circular path to point to different locations in the northern sky, but always angled 23.5 degrees away from a line perpendicular ("normal") to the orbital plane of the Earth (known as the "obliquity" of a planet). This circle in the sky is known as the "precessional path" of the Earth's axis, like the circle described by the top of the axis of a wobbling top. By today's observations, it takes 26,000 years to complete the wobble. [\[note 5\]](#)

I will propose that the spin axis moved directly and in a very short period from a location "among the stars of Ursa Major" to a new location in the sky near the current precessional path close to Ursa Minor and then halted, changed direction, and continued at a right angle very slowly. I think this happened in 685 BC during the 40 days when Venus and Mercury blazed in the sky. The nova event of the Sun would have represented an absolutely gigantic electric storm capable of twisting the Earth's rotational axis. I will thus suggest that the blazing of Venus and Mercury, and the simultaneous change in the location to which the Earth's spin axis pointed, were caused by a mass expulsion from the Sun -- a nova event. This was not a single hit, it was an expulsion that lasted 40 days. [\[note 6\]](#)

Attributing the cause to an electric storm from the Sun does not seem so far-fetched. I would find this an acceptable hypothesis because the effect would have represented relatively low forces extended over a long period of time. The Earth's axis, although experiencing a bending torque, did not react in the typically violent manner that a gyroscope exhibits on the application of an impact force. It is, of course, possible that there were geological effects but these remained completely hidden among the constant earthquakes experienced since the Earth shocks of 747 BC and 686 BC. Earthquakes continued at a high frequency for a long time. Eight hundred years later Rome still reports 57 earthquakes in a single year (Velikovsky). [\[note 8\]](#)

[Image: The comet NEAT in 2003, meeting up with a coronal mass ejection (CME) from the Sun, a minor nova event. The larger disk blocks the Sun's corona. The smaller diameter circle represents the size of the Sun. After NASA.] [\[note 7\]](#)

It could also be suggested that the current precessional path of the spin axis -- the so-called wobble which we still experience -- is the last remnant of the event of 685 BC. A "wobble" is what gyroscopes experience, but only if the applied torque persists. But since there is currently no applied force, and precession has not stopped, it is more likely that precession is caused by the Moon's travel around the Earth on a path which each month moves the Moon out of and back into the Earth's plasmasphere. The Moon is the only satellite of any planet which does this. All other satellites of all the other planets travel within their planets' plasmaspheres, except for a few satellites which remain completely outside of planetary plasmaspheres. [\[note 9\]](#)

The Moon leaves the Earth's plasmasphere monthly because the Moon is on an orbit much further from its parent planet (Earth) than any other satellite of any planet, excepting the few really distant satellites of Saturn (at 6 and 11 million miles). At an orbit of 250,000 miles

(400,000 km), the path of the Moon extends beyond the boundary of the Earth's plasmasphere on the Sun side. The Earth's plasmasphere extends only to 80,000 or 160,000 miles (130,000 or 257,000 km), but much further on the night side -- the "shadow" of the Sun's electric field. Thus the Moon travels within the Earth's plasmasphere only on the night side. [\[note 10\]](#)

The entry and exit of the Moon into and out of the Earth's plasmasphere would result in electric effects at the boundary. This would affect the boundary of the plasmasphere locally with each entry and exit. The electric effects are experienced by Earth, just as the arrival of a coronal mass ejection (CME) from the Sun causes a temporary slowing of the rotation of the Earth, although the Earth always regains its rotational speed afterward. The effect of the Moon's entry and exit from the plasmasphere, however, is unlike the effect of a CME, for the disturbance is localized and always offset from the center of the rotational axis of the Earth. All exits are always at the leading edge of the Earth's orbital path.

Since precession was not noticed by the astronomers of antiquity until after 400 BC, we could reason backwards and suggest that the Earth's plasmasphere was more extensive (larger) before that time (probably before 685 BC) such that it would contain the Moon in its travels around the Earth. This would imply that the nova event in 685 BC reduced the size of the plasmasphere to where the Moon, since that time, would cut across the plasmasphere boundary. Since the size of the Earth's plasmasphere is determined by the electric field of the Sun, it suggests also that the Sun's electric field was reduced in 685 BC.

Most likely the relocation of the Earth's axis in space had a relatively quick onset and then a rapid exponential decline, so that much of the change was accomplished within the period of 40 days, but not so suddenly that the Earth would have been jolted -- as had happened frequently in the past. We have to posit these conditions because we know the change happened, and most likely happened at this time, but went unrecorded (but certainly not unnoticed), lacking violent physical effects impinging on the Earth. The blazing of Venus and Mercury and the lightning bolt from Jupiter were seen by anyone who looked up at the day sky. The rotation in the dome of the stars to a new location was noted, especially by sailors and eventually by astronomers. I do not consider it even a remote possibility that the rotational axis of Earth shifted geographically in any significant manner. The geographic location of the axis of rotation before 685 BC was at exactly the same place (the "North Pole"), as today. [\[note 11\]](#)

Velikovsky mentions a Vedic source which tells that the Earth "receded 100 yojanas" from its place. This is an interesting and significant data point, and turns out to be wholly correct when compared to other astronomical sources. The measurement most likely dates from after the 7th century BC, when the oral Vedic traditions were being transferred to writing in India and emended with contemporary historical events. One hundred "yojanas" is 720 km, or 447 miles, and would represent a change of 6.5 degrees in the latitude of stars overhead.

If the Vedic source noted that "the Earth receded 100 yojanas from its place," it would

indicate a noticeable single change in the skies. The wording seems consistent, because later Roman authors agree that the Earth had sunk towards the south. Pliny called it, "a slackening of creation." But this would only be noticed with a comparison of the night skies before and after 685 BC. The question becomes, "What in the skies stood higher up after the change?"

The position (or height) of the Sun would be an indication as would a change in the background stars of the polar axis. This change can only be accounted for with a change in the inclination of the spin axis to the Earth's orbital plane.

Allowing that the Indians were competent mathematicians (and they certainly were, our algebra is derived from them), it could be suggested that the 6.5 degrees (100 yojanas) represented the shift in the Earth's axial inclination in 685 BC. The axial inclination can be easily measured from the difference (before and after) of the elevation of the Sun at the winter or summer solstice (for example). That would suggest that the axial inclination of the Earth before 685 BC was 6.5 degrees different from the present 23.5 degrees -- it was 30 degrees. [\[note 12\]](#)

The location of stars with respect to each other in the dome of the stars would not change with a relocation of the polar axis (or even a new orbital inclination). Thus, as far as the geography of the Earth is concerned, north would still be north, and the other cardinal directions would still be where they were expected to be. The North Pole location in the sky, also would not assume a different elevation above the north horizon. Latitudes would remain the same, although they would have to be recalculated. The Sun and the planets would still travel on the ecliptic, against the same background of stars. None of the stars would shift with respect to each other.

Only the relationship of the stars to the horizon and the equatorial would change, plus the intersection of the equatorial with the ecliptic (the location of the equinox). This is what I have proposed in the previous chapter and from comparison with other data, this seems to be the case. I'll describe the change in the skies further below.

A clear indication of the changes in the axial inclination probably remains obscured as yet among Babylonian records. Velikovsky brings some of the confused records forward, but he uses these in support of other events, and nothing can be gleaned from their perusal.

The fact that the Earth's axial inclination was 30 degrees at an earlier time was verified when I started to look at alignments of Mesoamerican ceremonial centers with the surrounding mountains and volcanoes. See the chapter "Olmec Alignments" for details. The chapter titled "The Chilam Balam" includes other clear numeric instances. [\[note 13\]](#)

The Sky in Disarray

[Image: San Jose rock showing Ursa Major and Ursa Minor; courtesy of Keith Snyder.]

Even if I can only suggest the mechanism involved in these changes, I can be more certain in identifying the location in the sky to which the axis of the Earth originally pointed. There is a Lakota Indian myth or legend which states that, upon death, people enter heaven through a hole in the sky where there once was a star, located within the four stars known as "the stretcher" or "man-carrier" -- the box or pan of Ursa Major.

Physical evidence for this, notably far from the Mediterranean where we find most of the mythology, is an undated hand-sized smooth stone found in California by Keith Snyder. The stone had drilled holes which exactly match the stars of Ursa Major and Ursa Minor. The sizes of the holes which pockmark the stone are proportional to the brightness of the stars in the two constellations. There is one additional hole in the pan of Ursa Major which is not included in most contemporary star charts of the Big Dipper. It is inside the pan (the "stretcher") and just below the line connecting Megrez to Dubhe and closer to Megrez than Dubhe (noted with the arrow in the above image). [\[note 14\]](#)

Going by the Lakota lore, Keith Snyder thinks it is a missing star which is now a mythological hole in the sky. Going by the Saturnian lore, I think it is the previous center of the sky before 685 BC and the location of the *axis mundi* before the departure of the Gods in 3147 BC. This spot is no longer the center of the sky.

We can plot a line, from the old location in Ursa Major to the current precessional path of the North Pole, to suggest the path of the pole in the last 2700 years. On this basis the center of the sky shortly after 685 BC, after the change of the polar axis, was most likely located about six to eight degrees above the line connecting Megrez to Dubhe, and perhaps some distance

west (counterclockwise). [\[note 15\]](#)

This new location was between constellations -- which is why none of the sources describe the new location to which the pole moved. At the end of Ursa Minor, opposite from Polaris, closest to Ursa Major, there is a star named *Kochab*, which translates as "star" from Arabic, but has been referred to in ancient sources as the "pole star." This is the one star of Ursa Minor nearest to Ursa Major, and also the star closest to the most likely new location of the polar axis. [\[note 16\]](#)

When the polar axis relocated, the circle of the equatorial would have relocated. The equatorial is a projection of the Earth's equator into space. It is thus a flat plane extending above (out from) the equator. Seen from Earth it is a circle in the sky connecting the east and west cardinal locations which is tilted at an angle above the south horizon equal to the complement of the latitude where it is observed (90 degrees less the latitude). This new equatorial cut a new path through the dome of the stars. The Universe had been defaced and the constellations had moved, claimed the ancients. But what moved, or seemed to have moved most significantly, was the relationship of all the constellations and the zodiac to the horizon. [\[note 17\]](#)

The other circle in the sky is the path of the zodiac, the ecliptic, a circle which wobbles on a daily basis, and differently during different times of the year (because of the tilt of the Earth's axis). The overhead part of the zodiac moves up and down over the course of the year, traveling some 47 degrees up from its lowest position.

The intersection of this circle with the eastern and western horizon shifts from north to south (and in the reverse) in the course of each night, only standing still on the two nights of the equinoxes. (The location where the zodiac dips below the horizon changes much less in the tropics.) But one quickly gets used to this, even today, without the "zodiacal glow" which had clearly defined the ecliptic up to the early 19th-century AD; the location of the ecliptic in the sky can readily be found by spotting one or two of the planets or the Moon which move along the path.

If you live where the night sky is unaffected by electric lights or the pollution which enshroud our cities today, you become familiar with the stars. When these are identified in groups, the familiarity extends to the ability to recognize a constellation on a partially clouded night from as little as two stars. As the sky rotates each night, it seems to move constellations up and down in the sky as it rotates, expanding and contracting them. Changes happen also because at different times of the year we see different portions of the dome of the stars. But, despite these distortions, constellations can be easily recognized because the changes from night to night are minor.

However, when you move to a different latitude from where you grew up, it is initially very difficult to locate the constellations with which you were familiar. Nothing looks right; all the stars are in the wrong places. And that is what happened when the night sky was "defaced" in

the year 685 BC. This rearrangement of the dome of the stars was noticed even as the changes were happening. [\[note 18\]](#)

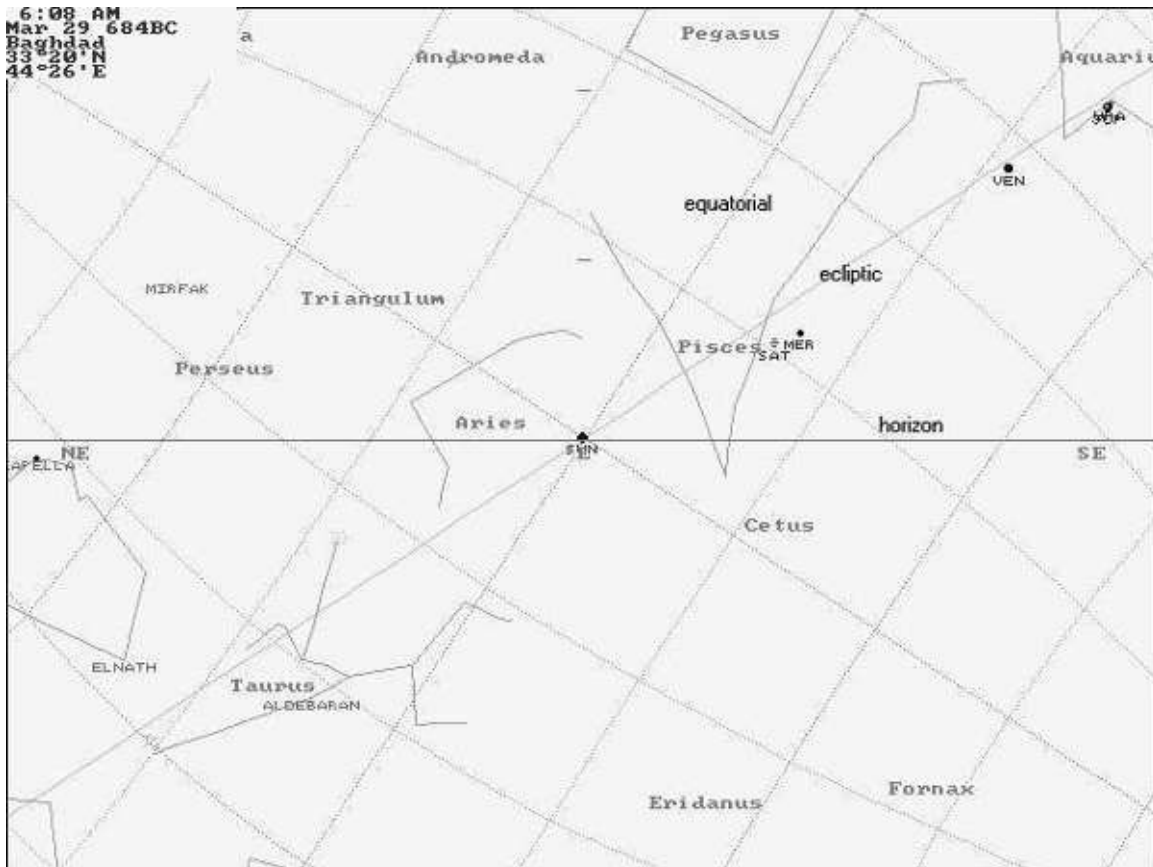

These were not minor changes. If, as Hindu records suggest, Ursa Major slid down 6.5 degrees, we are talking about some constellations changing their location with respect to the horizon by 13 diameters of the Moon. Constellations directly below Ursa Major (like Leo) would have seemed to move down and constellations 180 degrees removed (like Aquarius) would have seemed to move up. Constellations east or west of these would have moved less.

There are numerous references to the changes in the dome of the stars, a "defacing of the Universe." Velikovsky notes many of them, but inevitably applies them to the wrong events, or places them in the wrong era. The very fact that the changes in the dome of the stars were remembered are an indication that they refer to a late era. I would propose that all these references date to 685 BC and after. None were remembered from 1492 BC when the inclination of the rotational axis changed from 25 degrees to 30 degrees.

To date there has been not the slightest inkling among catastrophists of the event of Phaethon as described in these pages. Extra-terrestrial objects named "Typhon," "Phaethon," and "Apep" plus planetary thunderbolts are all guessed after and transformed like so much silly-putty, but nothing has been put in chronological order, correctly identified, or explained physically.

A Change in the Equinox

As the polar axis relocated, so did the intersection of the two great circles in the sky -- the celestial equatorial and the ecliptic. The two locations where these cross determine the rising of the Sun directly east on the vernal and autumnal equinoxes.

[Image: The equinox after 685 BC at 15 degrees of Aries as measured in antiquity. Looking directly east. The horizon, equatorial, and ecliptic are marked. The date is on the Julian calendar. Illustration by J. Cook, after SkyGlobe 3.6.]

In 129 BC Hipparchus measured an annual "drift" of this intersection based on an 80-year record from a contemporary source. He found that the vernal equinox moved 46 seconds (of a degree) west each year -- west, that is, along the ecliptic, so that each later year the Sun would rise slightly further along the zodiac. This slippage has remained more or less at the same value. Today the accepted value is 49.6 seconds of a degree per year. [\[note 19\]](#)

As the polar axis moves, so does the equinox, slowly moving westward from one constellation of the zodiac to the next. Today the Sun rises at the vernal equinox near the beginning (the west end) of the constellation Pisces. If we calculate 2700 years back we find that the Sun rose at 15 degrees of Aries in 685 BC, which is at the center of the constellation Aries. (The "15 degrees of Aries" above is with respect to the delineation of the Zodiac in

antiquity, which places zero degrees of Taurus, 30 degrees of Aries, at a location directly between the constellations Aries and Taurus.)

[Image: The equinox before 685 BC. As depicted here, the horizon line should be rotated 15 degrees counterclockwise (the stars moving clockwise), which will place the Pleiades almost directly above the rising Sun. Illustration by J. Cook, after SkyGlobe 3.6.]

Today the division of the ecliptic into 12 segments has no relationship to the original constellations or the measurements used in antiquity. Today "zero degrees of Aries" is arbitrarily assigned to where the ecliptic and the equatorial currently cross. This defines the first day of spring for us. This is done for timekeeping and celestial navigation. Today this is not in the constellation Aries, it is actually near the west end of the constellation Pisces. In AD 150 Ptolemy was already suggesting placing "zero degrees of Aries" at the location of the equinox -- for the purposes of astrological charts.

I contend that before 685 BC (the shift in the polar axis), the equinox was located directly between the east end of Aries and the west end of Taurus -- at the start of Taurus. There are a number of indications which all point to this. The change happened in 685 BC and was spread over 40 days. The *Chilam Balam* notes the Sun "left its path" for 40 days. The most notable record from the Eastern Mediterranean is a section of the *Sibylline Oracle Books*. Although written nearly 800 years later, it recollects events spanning the movement of Venus and the Sun over a number of constellations which would account for the same time period.

But what I find more convincing, is that the Pleiades were held to be the start of spring worldwide, and if not associated with the start of spring, then the autumnal equinox, when the Pleiades culminated at midnight -- rose to the highest point in the sky -- and thus also rose when the Sun set. After 685 BC it was discovered that the Pleiades no longer signaled the start of spring and that Taurus no longer started the cycle of the year. The fall culmination of the Pleiades had moved 15 days also. [\[note 20\]](#)

The Pleiades are an easily recognized cluster of stars located directly between the constellations (and zodiac houses) Aries and Taurus. But if we retrocalculate the skies on the basis of today, then in 685 BC the Pleiades did not start spring, nor, for that matter, and again by retrocalculation, for thousands of years earlier. This is because a retrocalculation does not account for the 15-day jump in 685 BC. [\[note 21\]](#)

Zero degrees of Taurus is also the only location in the whole of the zodiac which falls exactly between two constellations. This is peculiar, but, as I surmise, it was purposeful at an earlier time. The constellations of the zodiac do not occupy equal 30-degree spaces, and the constellations assigned to any of the 12 segments ("houses") are very arbitrary. The division of the 360 degrees was probably made long before 747 BC, when the year consisted of 360 days and the Sun would move one degree each day throughout the year. The sky of 360 degrees had been divided into 12 segments to match the 12 revolutions of 30 days of the Moon during the year at that time.

The zodiac had been established in Babylon probably since 1000 BC, or much earlier, since in the *Enuma Elish*, written in 1700 or 1600 BC, Marduk had ordered the constellations of the zodiac when he recreated the world -- when they became visible after removal of the Absu (in 2349 BC actually). Although originally consisting of 18 constellations, and thus of 20 degrees each, these had been reduced to 12 constellations. [\[note 22\]](#)

The Pleiades are seen as a cluster of seven stars located at the leading horn of the constellation Taurus -- just east of zero degrees of Taurus (in the zodiac as in use in antiquity). The location directly at the start of Taurus places the Pleiades almost directly above the rising Sun. [\[note 23\]](#)

The Pleiades had been held by almost all people of antiquity (including India, China, Mesoamerica, and South America) as the first index of spring. For people throughout the world, the sight of the Pleiades in the east just before sunrise -- when they had not been seen in the skies for six months -- signified the coming of spring and the start of the new year. Hindu calendar reforms after 600 BC mention that "the people wanted to have the year start [again] at the first showing of the Pleiades."

On the other hand, it has to be admitted that the return from death of Jupiter two nights after the autumnal equinox of 2349 BC -- rising up directly below the culmination of the Pleiades - - was remembered and celebrated for thousands of years. But this was a midnight showing of the Pleiades.

With respect to the division of the year into zodiacal houses, I would suggest that long before 685 BC a system of measurements had been imposed which had purposefully placed zero degrees of Taurus (which is 30 degrees of Aries) exactly at the midpoint between the constellations Taurus and Aries, and almost directly below the Pleiades. This lines up with the edge of the first horn of the bull Taurus, and will show the Pleiades above the horizon at the equinox -- and in line with the rising Sun. I suggest this was done because this location had been the start of the year forever, and was the location from which everything else on the zodiac was measured -- in 30-degree increments, each representing 30 degrees of movement of the Sun originally. [\[note 24\]](#)

After the change in the heavens in 685 BC, the zodiac sign in which the Sun rose on the first day of spring was significantly different. An ephemeris program which keeps track of precession will show that, after 685 BC, the Sun rose at the equinox as the constellation Aries was at the horizon, rising at the center of Aries. This was at 15 degrees of Aries, as measured in antiquity.

A few hundred years later, in 200 to 100 BC, the Sun rose at the equinox on the longitudinal line for Mesarthim in Aries. This was identified in antiquity as "8 degrees of Aries." Retrocalculation from 200 BC to 685 BC, shows that the Sun rose 7 degrees east of Mesartim. Thus after the displacement of the pole in 685 BC the Sun rose at $(7+8=)$ 15 degrees of Aries, as was also suggested above. [\[note 25\]](#)

The nova event of Venus in 685 BC moved the equinox 15 degrees. The vernal equinox thus rapidly shifted from the Sun rising at the beginning of the constellation Taurus to rising in the center of Aries. Before the changes of 685 BC, the constellation Taurus was already partially above the horizon as the Sun rose at the equinox and this had been so for centuries. The "Age of Taurus," with all the connotations attendant to the horned deities of antiquity, did not gradually slip into the "Age of Aries" -- the age of lambs and shepherds. The change came suddenly in 685 BC.

The change in the location in space to which the rotational axis of the Earth pointed is a change in the inclination of Earth's axis with respect to the orbit. After 685 BC the Earth was differently inclined toward the Sun; the climate would have changed. However, the change in the axial inclination would not significantly move the tropics or temperate zones, although it would move the Arctic Circle with respect to the pole. It would also not change the seasonal variation in climate. Climatic disturbances and fluctuations have been noted, however. [\[note 26\]](#)

The orbit of Earth also remained the same. Only the starting date of the year shifted -- by two weeks. A relocation of the vernal (and autumnal) equinox did not alter the calendars and would not have been of note to farmers. Farmers do not use calendars to determine the time for planting, they use the weather. [\[note 27\]](#)

Although the altered sky was noted by everyone, the change in the equinox was only noticed

by the astrologers and philosophers of the Middle East, Europe, China, and Mesoamerica. The sky had not really been thrown into disarray, but it had been moved -- suddenly twisted - - and, as was later observed, the equinox continued to rotate ever so slowly through the constellation Aries and further away from Taurus. It invalidated the tables which were used in Babylon to determine the start of the year and the predictions of lunar eclipses. The paths of the planets were confused and those tables also had to be redone. Comments have been made by 19th-century researchers about the records left by the Chaldean astrologers from this period (after 650 BC), mostly suggesting that the astrologers were making things up and paid no attention to the actual skies. [\[note 28\]](#)

At Nineveh, the principal city of the Assyrian kings, Assurbanipal founded a library in the 7th century. The library collected copies of temple records throughout Assyria and Babylonia, which included topics ranging from literature to mathematics and many letters of the kings of Assyria. When the combined forces of the Medes, Persians, and Chaldeans attacked Assyria in 621 BC, and leveled Nineveh, the library burned down, turning the clay tablets to fired clay.

David Brown, in *Mesopotamian Planetary Astronomy-Astrology* (2000), has investigated the astrological (astronomical) texts from this library in light of the extended correspondence between the Assyrian kings and the astrologers and scribes in their employ. [\[note 29\]](#)

John M. Steele, in a review of Brown's book, wrote:

"He [Brown] contends that all of the extant texts that are believed to have originally been written before the eighth century B.C. fit into a [earlier] paradigm that had no interest in predicting celestial events, and that we should see the period schemes, intercalation rules, etc. found, for example, in 'Enuma Anu Enlil' and 'MUL.APIN' as being aspects of celestial divination, not primitive or inaccurate astronomy."

Writers in the history of science, including Brown, have dismissed documents like the *Mul.Apin* by pointing out that it was obviously written around the concept of an "ideal" year of 360 days and an equinox at the rising of the Pleiades. I would suggest, however, that the *Mul.Apin* (which mostly consists of a chart of constellations) was indeed accurate in the era before 747 BC, despite the purpose, both before 747 BC as well as after, of divination. That does not detract from the *Mul.Apin*'s status as a "scientific" source document for the Babylonians.

I suspect that lunar eclipses were not experienced at Babylon before 747 BC. Before that time the Moon's orbit was larger (30 days), and only after 747 BC, when the Moon's orbit had shrunk to 29.5 days, did it come close enough to Earth to have the umbra of its shadow show up on the surface of Earth. Even today, because of variations in the Moon's orbit (it has an eccentricity of 0.05), the shadow at times does not show.

This would explain why the first documentation of an eclipse is from 721 BC. When the

eclipses started to appear sometime after 747 BC, they were frightening, especially since these earlier solar eclipses were caused by Mars -- and inevitably accompanied by earthquakes, hurricanes, and electric bolts from the heavens.

The extensive correspondence between the kings and the astrologers was for the obvious reason that the skies had changed in 747 BC and again in 685 BC. There was a sudden urgency to develop correct methods of predicting lunar and solar eclipses, which showed up two to four times per year, and were totally unpredictable. The Babylonians never did figure out how solar eclipses were caused -- and little wonder, if their data included solar eclipses caused by Mars. Ptolemy, 800 years later also never found a means to predict solar eclipses. But by about 700 BC the lunar eclipses were correctly modeled and became predictable. Then after about 686 and 685 BC the skies changed, and all the calculation had to be started over. [\[note 30\]](#)

There is only a sprinkling of documents from before 747 BC because only the useful documents were retained. The *Mul.Apin* certainly was one of these, even if the year was no longer 360 days. Also retained was the *Enuma Anu Enlil*, a record of observations, detailing celestial events, water levels of the Euphrates, and economic indicators (like the price of barley). The *Enuma Anu Enlil* records included the *Venus Tablets of Ammizaduga*.

Special thanks to K Snyder for pointing up the San Jose rock.

Special thanks to S Bourke, AU, for the Kirkin story.

Special thanks to J Brookes for suggesting the Moon as the cause for precession.

Endnotes

Note 1 --

A more extensive derivation will be found in the chapters "The Chilam Balam books" and "Olmec Alignments." This requires a familiarity with the Mesoamerican calendar, described in the chapter "The Maya Calendar," and Mesoamerican thinking, some of which is discussed in the chapter "Language and Causality."

[\[return to text\]](#)

Note 2 --

A distinction should be kept in mind between popular narratives about the creation of the world and actual events. The *Chilam Balam* relates the sequence of four instances of actual events of the past. But these were copied from the official records. What we see in the *Popol Vuh* is a constructed narrative, made at a time when the Maya considered all of history as repeating itself endlessly anyway, so that sequencing events separated by 4000 years was not

a conceptual or philosophical problem. The authors of the *Popol Vuh* claim they had the official histories at hand, and, in fact, many details slip into the story of the *Popol Vuh* which could only have come from very old codexes.

[\[return to text\]](#)

Note 3 --

In Europe away from the Mediterranean, throughout Northern Asia, and in North America the constellation "the Wain" was known as "the Bear," apparently since remote antiquity. Only by considering the Wain as representing a bear with four long legs extending below the pan of Ursa Major could this constellation be considered as dipping into the ocean. The Romans, however, did not consider Ursa Major as representing a bear. It was a wagon which endlessly circled the sky at the location of the old polar axis.

[\[return to text\]](#)

Note 4 --

"The Wain" is here translated from the Egyptian equivalent, an ox, a mummified ox, or a mummified ox leg, graphically depicted as early as 1500 BC, with an axis piercing the body of the ox. The fact that this has remained the same suggests that there was no precession of the equinox before the relocation of the rotational axis in 685 BC.

"Looking among the stars of Ursa Major" is also described in formal texts in the temple at Denderah, which was built (or rebuilt) in Roman times -- thus some 600 or 700 years after the polar axis had relocated away from Ursa Major.

Attempts in the 19th century to date the first Chinese emperor Yao to 2350 BC, by a retrocalculation based on precession which places the Pleiades at the vernal equinox are baseless, despite the fact that the results agree with the dating estimates made during the Han dynasty, by the compilers of the *Annals of Shu*, which did not involve the precession of the equinox. The Han dynasty scribes have the Pleiades appear at the spring equinox.

Why the compilers of the *Annals of Shu* would add this strange information in the 7th or 8th century BC, (which could be suggested from the fact that other astronomical and calendrical information was added at the time of the Chou or Han), is unclear, for by today's retrocalculations, the Pleiades did not define the vernal equinox in 700 BC, or, for that matter, as early as 1500 BC. Legge notes this in his commentary on the *Annals of Shu*.

Similar retrocalculations have been made in India in the last century for the start of the current era and for the Bharata battle (and placed variously at 3037 BC and 1432 BC), based on hints from the Vedas. However, all these strange retrocalculations can be resolved. See for this "A Change in the Equinox" in this chapter.

[\[return to text\]](#)

Note 5 --

The 26,000-year cycle is based on only a few hundred years of observation, equivalent to watching the passage of about 1 or 2 degrees of the 360 degrees of the path. The rate of precession, which currently is a movement of about one degree every 72 years (since AD 1600), has been known with some accuracy since the first century BC. There have been periods of time when the precession stopped, and when the value differed markedly from today's value.

Uwe Topper in "Cataclysms are the reason for our wrong chronology" *International Meeting of Chronologists*, Potsdam, 2008 (<http://www.ilya.it/chrono/pages/>), notes that the historical value for the number of years per degree has varied from 50 years (some early Babylonian sources in 330 BC, although this is disputed) to an early Greek value of 100 held by Aristarchus (210 BC), Hipparchus (130 BC), Ptolemy (AD 200), and confirmed by early Arab astronomers. Later Arab and European astronomers from AD 800 to AD 1300 used a value of 66 years. The current value of 72 years has been maintained since Kepler (AD 1600).

The "wobble" of the axis is not related to the wobble a spinning toy top experiences when the upward force at the support point at the bottom and the downward force of gravity through the center are displaced by some distance, forming a torque about the horizontal center. In the case of a toy top, the precession is the result of a torque which continues to be applied. Obviously, nothing of the sort is experienced by the Earth.

[\[return to text\]](#)

Note 6 --

Electric effects such as these cannot be neglected. In the thirty years since the spin of the Earth has been measured with atomic clocks, the Earth has slowed down by 30 seconds in its rotation. This is much larger than what can possibly be accounted for under present theories of astrophysics (which, however, excludes electric considerations).

[\[return to text\]](#)

Note 7 --

"The Sun's glare prevented observers on Earth from viewing NEAT's approach. But the SOHO spacecraft, stationed between Earth and the Sun, has an instrument called Large-Angle Spectrometric Coronagraph (LASCO), which blocks the Sun's brightest light, permitting the satellite to record the comet's dramatic swing around the Sun."

"As NEAT raced through the extended solar atmosphere, a large coronal mass ejection (CME) exploded from the Sun and appeared to strike the comet. The comet responded with a kink that propagated down the tail. The disk in the center is created by the coronagraph as it blocks the Sun's glare."

[\[return to text\]](#)

Note 8 --

It might be suggested that the change in the Earth's axis was due to another approach of Venus, as regularly happened at 52-year intervals (supposedly) in the remote past. Since 1492 or 1442 BC, the "52-year intervals" of close approaches of Venus have been 50 years up to 747 BC, and 52 years thereafter. See Appendix B "The Celestial Mechanics," where this information is developed.

Adding 50 or 52 years (or multiples) to the dates which could be identified as a previous approach of Venus (776 BC) does not yield a date anywhere near 685 BC.

[\[return to text\]](#)

Note 9 --

From an essay by Walter Cruttenden, "Comparison of Precession Theories: An Argument for the Binary Model" (Internet, 2003):

"It was Sir Isaac Newton, who had just developed his theories of gravity that said if the Earth did wobble it must be due to the mass of the Sun and the Moon, the only bodies considered close enough or large enough to have such an effect. But Newton's equations never did match observed precession rates."

"Consequently, the equations were substantially revised by Jean-le-Rond D'Alembert who added factors for torque and inertia, but even this effort proved a poor predictor of precession rates."

"Since then precession calculations have been continually modified and now include many factors beyond the original 'lunisolar forces,' including the gravitational effect of the inner and outer planets, tidal influences, effects of the 300 largest asteroids, and even a possible elliptical movement of the Earth's soft core."

"But as is apparent the calculations have become more of a 'plug' whereby inputs are gradually added or modified to fit the observation rather than being predictive or resting on solid theory."

[\[return to text\]](#)

Note 10 --

The orbit of the Moon is 250,000 miles (400,000 km). The plasmaspheres of planets extend

10- to 20-planet diameters from the surface, thus 80,000 to 160,000 miles (129,000 to 260,000 km) for Earth.

side view of orbits

Path of the Moon over a Six-Month Period

The Moon follows a spiral path which reversed in the up-down direction every six months

Additionally the Moon's travel takes it some 20,000 miles (32,000 km) alternately above and below the Earth during the year. This affects the date when eclipses will be seen, but has little effect on its entry and exit from the Earth's plasmasphere. The actual travel around the Sun describes a cycloid pattern -- not a series of semicircles.

Path of the Moon during a month

The Moon spends most of its orbit outside of the Earth's plasmasphere

Note 11 --

Alfred de Grazia, in *The Lately Tortured Earth* (1983), writes:

"Yet Velikovsky, arguing the case for axis displacement, had earlier discussed a calculation by Weizacker demonstrating that an Earth transaction with a strong magnetic field would affect its axial inclination much more readily than its rotation [13]."

The reference is to an article in *Pensee*, by William Straka, "Straka: Science or Anti-Science," (1972). From what happened to the Earth's magnetic field in remote antiquity, that is, before 10,000 BC (see the chapter, "Event of the Younger Dryas), we know that this is not true. The possibility of a magnetic couple, induced by the extreme Solar Wind passing by Earth, is as unlikely, since the planets' magnetic poles do not coincide with the axis of rotation. A constant applied torque is required, which calls for a force applied off-center from the Earth's axis. See Appendix B, "The Celestial Mechanics."

Note 12 --

[Image: The intersection of the ecliptic and the equatorial, in Summer of 685 BC.

Illustration by J. Cook.]

Although a yojana is a terrestrial land measure (distance), it can be projected to the sphere of the stars which surrounds the Earth as a change in celestial latitude. A north-south distance of 100 yojanas on Earth represents a 6.5-degree change in latitude. The same angular measure would apply to the dome of the stars. A 6.5-degree change in celestial latitude in 685 BC would place the earlier location of the rotational axis of the Earth directly in the pan of Ursa Major.

By itself, a 30-degree axial tilt will make only a minor difference in climate compared to a 23.5-degree tilt. The Arctic Circle would move closer to the pole by 6.5 degrees.

The triangle defined by the old and new equatorial projected onto the Earth (the ecliptic remains the same) determines how far the equinox advanced along the ecliptic -- and thus how many days were lost in 685 BC. The intersection of the ecliptic and the equatorial is the equinox, and thus the start of the year. The amount that the equinox advanced along the ecliptic (from the old equatorial to the new equatorial) is found from considering the angles and spherical segments.

From the relationship for spherical triangles, $\sin c / \sin C = \sin a / \sin A$, $\sin c$ is found as:

$s(c) = s(\pi/2) * s(6.5/\text{deg}) / s(30/\text{deg}) = 0.226$ which is 13.1 spherical degrees [as the arcsin of 0.226].

Along the ecliptic (segment c) this represents a fraction of a year of 365.24 days, thus **(13.1 / 360) * 365.24 = 13.29 days**. Thirteen days of my estimate of 15 days are thereby accounted for.

Using plane trigonometry, I calculate 14.74 days.

[\[return to text\]](#)

Note 13 --

Book 10 of the *Chilam Balam* includes three instances of spans of time, all given as so many months or years. I have not been able to make sense of any of these time spans except by recognizing that the original author in each instance counted inclusively.

The most significant statement in the text is, "*After three heaps of years it [the sun] will come back into place in Katun 3-Ahau.*" (The use of future tense is peculiar to the translation into an Indo-European language.)

A "heap" is probably 5 (elsewhere known as a "bundle") and a "year" is a 260-day Tzolkin year. The fifteen years is another of the instances of inclusive counting for it turns out that the "three heaps of years" represent an interval of 14 Tzolkin years in the Mesoamerican Long Count calendar.

Fourteen Tzolkin years correctly states the number of days it takes for the same day-name and day-number combination to recur for a sunset at the same horizon sunset location of the Sun before and after the change from the 30-degree axial inclination to a 23.5-degree axial inclination.

This simple fact is key to an understanding, because 14 Tzolkin cycles of 260 days do not bring us back to the same seasonal day in the year, or even present the same Tzolkin and Haab day-names of the calendar. Seasonally it falls short by about 12 days. The *Chilam Balam* thus says that the Sun set at the same horizon location as in the past, but 12 days earlier. This cannot be achieved except with a change in the axial inclination of the Earth.

I should point out also that the information as presented in the *Chilam Balam* probably refers to the setting location of the zenithal passage of the Sun at some location within the range of 15 to 20 degrees north latitude.

As I point out in the chapter "Olmec Alignments," zenithal passages of the Sun were important to the ceremonial centers of Olmec Veracruz and the Valley of Mexico. Nearly every center was aligned to have the Sun set at some mountain or volcano after a zenithal passage over the site. The difference of 12 days suggests that the information of the *Chilam Balam* was originally recorded for a latitude of 17.0 degrees (possibly Monte Alban). See the chapter "The Chilam Balam" for additional details. This is one of the clearest indications that there was a change in the axial inclination of the Earth -- in fact, from 30 degrees to 23.5 degrees.

[\[return to text\]](#)

Note 14 --

I am indebted to Keith Snyder, who found and recognized the stone, and mentions the Lakota source in Ronald Goodman, *Lakota Star Knowledge: Studies in Lakota Stellar Theology* (1990), on his website at snyder_kas.home.mindspring.com/Indian_Stones.html. If the legend is still current, the age of the drilled holes does not matter.

The missing star might not be missing. A star exists at the designated location, although dim, with a magnitude of 6.1.

Interestingly, the centroid of the stone looks to be halfway between Ursa Minor and Ursa Major, at about the star Kappa in the constellation Draco. This is about where I would expect the axis of the sky to have moved in 685 BC, before eventually settling down near Kochab in Ursa Minor.

[\[return to text\]](#)

Note 15 --

East and west in the dome of the stars is defined by the direction the stars seem to rotate. Facing south, west is to the right. Facing north, the stars above the pole star move left to the west; the stars below the pole star move toward the right, where the geographic east is located.

The original location of the axis within the pan of Ursa Major would be at 58.5 degrees of elevation, and a Right Ascension (RA) of 11.7 hours. Right Ascension is the number of degrees from the current vernal equinox, expressed in hours, where 360 degrees represents 24 hours.

One of the ball-playing twins of the *Popol Vuh*, who represents Venus in 685 BC (Hun-Ahau, Hunahpu), has to shoot down the bird Itzam-Yeh (Seven-Macaw), who had perched on top of the central axis of the sky, the World Tree, before a new creation could start. Itzam-Yeh, Seven-Macaw, today is thought to be Ursa Major. The image above describes the removal of Ursa Major as the center of the sky, but from the perspective of Mesoamerica. The bird reference, however, is to Saturn at the polar location before 3147 BC.

[Image: A pottery Image: Hunahpu shoots Itzam-Yeh (Seven-Macaw). The text reads, "Done by Hun-Ahau; on 1-Ahau 3-Kankin he entered the sky, Itzam-Yeh." After David Freidel and Linda Schele "Maya Cosmos" (1993).]

The scorpion below the tree is the constellation Scorpio at the base of the Milky Way. Scorpio has the same name in Mesoamerica as in the Eastern Mediterranean. There is a snake on the left (not shown here) which is the constellation Sagittarius. Therefore the North Pole is here shown from the perspective of the south, and thus is upside down. But it is seen, not

from the south horizon, but from the edge of the Absu, somewhat below the equatorial. This is not really such an outrageous presentation. The jaguar paw reaching out from behind the tree trunk is often identified as Xbalanque, but it is the hieroglyphic sign for "te" (tree), and used together with the glyph "yax" on the other side of the tree trunk, identify the tree as "yax-te" or ceiba tree.

In Classical Maya cosmology the Milky Way has replaced the World Tree, which originally was the polar configuration from before 3147 BC, but forgotten by the Maya nearly 4000 years later, and only recalled from ancient graphical books. That the Milky Way is the World Tree is the opinion of archaeologists. See David Freidel and Linda Schele, *Maya Cosmos* (1993), and Dennis Tedlock, *Popol Vuh* (1985). However, the Milky Way does not intersect Ursa Major.

The date of 1-Ahau 3-Kankin is curious, for it does not match the Maya retrocalculated date of 4-Ahau 8-Cumku in 3114 BC usually listed for this event (actually as the *completion* of the previous creation). The date 1-Ahau 3-Kankin, as Freidel and Schele note, would correspond to May 28, 3148 BC Gregorian, more than a year before my date of 3147 BC. Actually it is -3148 in numerical notation, which is 3147 BC in BC/AD notation. This would suggest either the date at which Earth was released from Saturn (which would be the Earth's aphelion), or the date at which the removal of Saturn was complete (as, for example, the end of the World Flood). I'll cover this in a later chapter.

[\[return to text\]](#)

Note 16 --

The Hindu poem *Mahabharata* notes a number of locations for the pole star, which are all below the precessional path of the pole star as understood today. They are correct in Right Ascension for the 8th through the 5th century BC (when the poetry of the Mahabharata was created), but too far below the path of the pole as described today. These locations would also not hold for a more remote antiquity. Backward in time from today, the currently defined path of the pole bisects the region between Ursa Minor and Ursa Major and curves toward the tail of Draco. Scholars who have analyzed the astronomical data of the Mahabharata have taken note of the Right Ascension (before 685 BC) to place the war in 1400 BC, but have failed to take the altitude into consideration. See S.P Gupta and K.S. Ramachandran (editors), *Mahabharata, Myth and Reality* (1976).

Note 17 --

The horizon is probably the most important anchor point in visually recognizing and locating constellations.

[\[return to text\]](#)

Note 18 --

At age 12 I moved from 55 degrees latitude to 42 degrees latitude. It took years before I could again instantly recognize constellations which I had learned earlier in childhood. And there were new ones.

[\[return to text\]](#)

Note 19 --

The Babylonians (Chaldeans) may have noticed the precession about 50 years earlier than Hipparchus. In China, Yu Hsi noted the precession of the equinoxes around AD 330. John Henderson writes:

"This discovery is traditionally attributed to the fourth-century astronomer, Yu Xi ([AD] 307-338), though astronomers as early as the Han era had noted that the winter solstice shifted with respect to the lunar lodges."

-- John B. Henderson "Cosmology and Concepts of Nature in Traditional China" (essay, nd)

The Han spans 206 BC to AD 220. The "lunar lodges" are the houses of the zodiac.

[\[return to text\]](#)

Note 20 --

Patten and Windsor, in *The Mars-Earth Wars* (1996), similarly come to the conclusion there was no precession of the equinox in antiquity, but use 701 BC as the terminal date of that condition.

[\[return to text\]](#)

Note 21 --

In the first and second century BC it was universally accepted by all the Mediterranean civilizations that the vernal equinox was located at 8 degrees of Aries. This is actually a peculiar location, and certainly not selected by design at that time. The reader will realize that there is no way for a slipping equinox to have started at zero degrees of Taurus and have moved to 8 degrees of Aries in the span of a few hundred years under current conditions.

[\[return to text\]](#)

Note 22 --

Almost all people everywhere established some sort of division of the night sky into 12 or 13 regions of marked significant stars, all to the purpose of noting the passage of the Moon. The Egyptians at a very early time used 36 notable stars for timekeeping at night. India divided the sky up into 28 sectors (called mansions) marking the progress of the Moon. This was a system dating from a yet earlier era. The Chinese year was also divided into 28 "lunar

mansions" -- long before contact with India. We know of the Chinese divisions from Shang dynasty inscriptions at least since 1400 BC.

China reduced the zodiac to 12 constellations in about 100 AD, during calendar reforms. The new Chinese constellation names were both indigenous and received from Indian sources, who in turn copied Babylonian constellation names under Alexander's Greek influences after 330 BC. The European Greeks, and eventually the Romans, did the same, substituting Babylonian names for earlier local names. Thus the entire Asiatic and European zodiac of today derives from, or was modified from, the zodiac in use in Babylonia -- but in all cases long after the constellations were named in Babylon. See calendar notes in Appendix A, "Chronology."

The earliest surviving description of the Mesopotamian constellations is the *Mul.Apin* tablet series, with the oldest dated example from the 7th century BC. "The *Mul.Apin* was not a marginal source, but probably forms our most important document for ancient Mesopotamian astrology." -- vd Sluijs. The *Mul.Apin* marks the vernal equinox and autumnal equinox as follows:

"MUL.MUL (eta-Tauri, the Pleiades) and GIR.TAB (beta-Scorpii) were visible at the East and West points of the horizon and also defined the Vernal and Autumnal Equinoxes."

-- from <http://www.lexiline.com/lexiline/lexi171.htm>

This has led some to suggest that the tables date from 2340 BC, on the basis of a retrocalculation based on today's skies and today's estimate for the precession of the equinoxes. This is a ludicrous suggestion, not only because of the extrapolation to such a remote date, but also because it assumes that no changes were made in the data for the next 1600 years even though the skies (on the basis of an implied "precession of the equinoxes") would have changed continuously. It cannot be believed that the zodiac descriptions remained stuck at a value determined for the year 2340 BC for thousands of years. See for instance, Werner Papke, *Die Sterne von Babylon* ("The Stars of Babylon") (nd).

Most researchers have neglected this information, and write about the *Mul.Apin* as if it represented "an idealized year of 360 days" with an equinox at the rising of the Pleiades, a similar idealization. The *Mul.Apin* certainly dates to before 747 BC, although the oldest recopied texts date with certainty only to 687 BC. By stylistic content of the dozen copies (from Nineveh, Assur, and another location), they date to perhaps 1000 BC.

About the ecliptic, and for a later date of 400 to 300 BC, Robert Powell, in "The Definition of the Babylonian Zodiac and the Influence of Babylonian Astronomy on the Subsequent Defining of the Zodiac," PhD Thesis, Polish Academy of Science (2004), writes:

"According to this original definition the zodiac is defined by the two first magnitude

stars Aldebaran and Antares in such a way that each is located exactly at the midpoint (15 degrees) of their respective sign, Taurus and Scorpio. Thereby these two stars define the central axis of the zodiac, which was the primary zodiacal reference axis for all other stars."

The first part of this statement is fact; the second part is guessed after. However, selecting Aldebaran as 15 degrees of Taurus places zero degrees of Taurus within two degrees of where I suggest the division of the ecliptic started in antiquity. If Taurus was not meant to be the first constellation to show above the horizon at daybreak at the beginning of the year, why was Aldebaran selected as one of the midpoints of the ecliptic? Powell continues with the suggestion of how the sidereal ecliptic was replaced by a tropical (solar) ecliptic -- where the equinox is set at "zero degrees of Aries" -- but has difficulty substantiating his claims (which I won't cover here). He does add a note on the selection of the equinox (apparently at a somewhat later date of 200 BC):

"Note that if there was a perfect correspondence between MUL.APIN's solar calendar and the zodiac, the vernal point would have to be located at 15 degrees Aries, since Aries as the first sign of the zodiac corresponds to month 1 and in the Babylonian solar calendar the vernal equinox was placed on the 15th day of month 1. However, in System A of Babylonian astronomy the vernal point was located at 10 degrees [of] Aries and in System B at 8 degrees [of] Aries."

Changes were made in the Babylonian record keeping, but the reasons for the changes have eluded any contemporary analysis based on a continuation of present conditions into the past. The three values for the equinox suggest that the change in the heavens may have taken some years to subside, although all other data contradicts this.

[\[return to text\]](#)

Note 23 --

Before 685 BC both the horizon line and the equatorial would be rotated about 15 degrees counterclockwise when viewed directly east. Thus the Pleiades would rotate 15 degrees clockwise with respect to the horizon, placing them almost directly above the rising Sun.

[\[return to text\]](#)

Note 24 --

Note that the choice of a location from which the circumference of the night sky is measured does not depend on how many zodiacal constellations are identified or the number of degrees assigned to each. Thus, if at an earlier time, the Babylonians identified 18 constellations of the zodiac it makes no difference to the starting point between Aries and Taurus. We know from records of the 4th century BC, that by that time the zodiac had been divided into 12 sectors of 30 degrees each, even though the original reason for a division into 12 houses was no longer valid and the constellations for which the "houses" of the zodiac are named were a

poor fit.

China was not wedded to a system which divided the night sky up into 12 equal segments of 30 degrees. The sectors of the sky were of unequal size, as little as 2 degrees, with boundaries along the longitudinal lines of easily recognized stars. Thus in 747 BC, when the length of the year changed, the Chinese had no reason not to reorganize the night sky over a full circle defined as 365.25 "degrees." This remained in use until circa AD 1400.

[\[return to text\]](#)

Note 25 --

There are suggestions that perhaps the initial displacement of the equinox was not 15 degrees, but something closer to 9 degrees. We are only certain of the complete displacement of 15 degrees in about 300 BC or 200 BC, when the equinox had moved well beyond the initial 15 degrees along the equatorial.

Velikovsky (p. 353 ff) discusses Talmudic references to calendar changes made by Hezekiah, mentioning a doubling of the month of Nisan (the post-exile name for the first month of the year) to celebrate Passover. The Talmud actually explains that this was done to adjust for the lunar year -- which lagged behind the solar year. These "corrections" would have been made after 747 BC. Hezekiah made many reforms after 747 BC, cleaning out the temple, reinstituting the priesthood, both of which had been neglected by his predecessor Ahaz.

With the Moon's period of 29.5 days, representing an odd interval of the year, which was 365.25 days since 747 BC, the religious festivals which had been signaled by visible aspects of the Moon, like the new Moon or the full Moon, now drifted around the year. Religious feast days fell 9 or 10 days behind with every following year.

This clearly shows up at least once when mention is also made in the Talmud that Hezekiah moved New Year's Day, normally celebrated at the fall equinox, back 9 days from the 10th day of the seventh month to the first. Velikovsky suggests that it was the fall equinox which had moved back 9 days. But there is no need to make this suggestion. I suspect it was a lunar adjustment, which would have failed again the following year.

Velikovsky also mentions Babylonian records of that era which at one point place the (spring) equinox at the 15th day of the month of Nisan, and on another clay tablet list it as the 6th of the same month -- 9 days difference. I suspect such differences are all due to the new orbital period of the Moon after 747 BC.

[\[return to text\]](#)

Note 26 --

Velikovsky notes for the 8th and 7th century BC (in an unpublished document at <http://www.varchive.org/tac/polturn.htm>, "Political Turmoil Around -687"), "*Climatic*

change was again very significant and oscillations of climate marked the ninety years from -776 to -687." This sums up information from his book, *Earth in Upheaval* (1955), where he also writes of the depopulation of regions north of the Alps.

These years include the period of frequent electric contacts by Mars, concluding with the (unrelated) nova event of 685 BC. Disturbances north of the Alps were also due to Mars when it continued to pass Earth on its orbit, which was inclined at an angle of 1.85 degrees to the orbit of Earth.

A depopulation of Europe, for that matter, is matched with similar demographic changes elsewhere. More properly, the demographic changes might be attributed to a combination of causes, involving not only climatic fluctuation, but the physical devastation due to some nine plasma contacts with Mars during this period, of which we certainly have a clear record for the cities and citadels of the Middle East.

The climatic changes were real; they are recorded in the tree pollen found in bogs.

[\[return to text\]](#)

Note 27 --

The length of the delay in the start of spring, 15 degrees, is equal to about 15 days. A degree is just short of a day. In an abridged version of James Frazer's *The Golden Bough* (Theodor Gaster, editor, 1959), a text entry reads, "The Greeks gather and press grapes in the first half of October." An endnote explains:

"In ancient Greece the vintage seems to have fallen somewhat earlier, for Hesiod (Works and Days, 609 ff.) dates it to the time when Arcturus is a morning star, which was on September 18."

This would place Hesiod's composition of *Days and Works* to before 685 BC. The date of September 18 is about correct under the composition of the skies before 685 BC and with a 15-degree displacement of the equatorial. Other details of *Works and Days* place its composition to *after* 685 BC, however.

[\[return to text\]](#)

Note 28 --

There are lengthy astronomical records made by the Babylonians, starting in the eighth century BC directly after 747 BC (and other records supposedly since circa 2500 BC), involving the planets, the Moon, and the path of the Sun. The equinoxes, the shortest and longest days of the year, the distance traveled by the Sun each day against the background of stars, were all noted. But most of the records we have date only from after 650 BC. It looks like in most cases the data from before 650 BC was discarded.

Velikovsky wrote that, at times, as many as three differing records were kept of the path of the Sun and planets, suggesting changes in the Earth's orbit during the 8th and 7th centuries BC. It is true that multiple records were kept in this era, in sets of three, by the Babylonians, as well as the Indians and Israelis.

But Velikovsky also added information from the *Mul.Apin* which he misunderstood. He refers to the Enlil path, the Anu path, and the Ea path as if they were separate trajectories of the Sun. The *Mul.Apin* "paths," however, are sectors of the sky concentric about the polar axis, representing the constellations rising, roughly, in the northeast, the east, and the southeast. They are named after appropriate gods, so that the Enlil region represents the "air" above the ecliptic, Anu represents the central region of the sky which includes most of the "river" of the ecliptic, and Ea represents the "waters" south of the central region.

Note 29 --

The period Brown has reference to is 750 BC to 621 BC. The correspondence with the astrologers was generated by the last kings of Assyria, Tiglath-Pileser III (745-727), Sargon II (721-705 BC), who took up residence at Nineveh, Sennacherib (705-681 BC) who rebuilt Nineveh, Esarhaddon (681-668 BC), and Assurbanipal (668-626 BC), who built the library which burned down in 621 BC.

[\[return to text\]](#)

Note 30 --

The records of Babylon were translated into Greek in antiquity (on Alexander's orders), but apparently everything before 747 BC may have been discarded at an early date as being unreliable. In fact, there is also a notable absence of records until about 650 BC. A number of people have pointed out that solar eclipses (due to the Moon) would not have been experienced in the region of Babylon during this era.

Ptolemy lists 721 BC as the first lunar eclipse seen in Babylon. The first recorded lunar eclipse in China falls in 720 BC. The Chinese *Spring and Autumn Annals*, spanning the years 722 BC to 481 BC, records 37 eclipses.

Jastrow: *Sun and Saturn*

The *Enuma Anu Enlil* records have been used by the Saturnians of Thunderbolts.info as one of the sources for the concept that Saturn was known in antiquity as "the Star of the Sun" and in fact was considered to be the Sun -- especially when translated as "Sun Star." Cardona and other Saturnians who have justified this position with reference to an essay by Morris Jastrow, "Sun and Saturn," written in 1910, have been faulted for ignoring some of Jastrow's comments.

To quote Leroy Ellenberger:

"According to Morris Jastrow, Jr., in his 'famous' and oft-cited article 'Sun and Saturn,' Saturn was not given a specific name until after Venus and Jupiter were named, which is surely strange if Saturn was the primordial deity described by the 'Saturnists.'" [\[note 1\]](#)

This sequence of naming, and similar faults, is entirely resolved if it is understood that this record (of the planets) was created in 685 BC or shortly thereafter. It explains everything. Note is made first of Mars and Mercury because of their interference with Earth since 806 BC. Venus was noted because in 776 BC it may have struck Mars (and the Moon) with a thunderbolt. Venus went nova along with Mercury in June of 685 BC. Mars and Mercury were also the two planets most frequently seen in the sky.

These planets were already in the record. Jupiter is noted next after it expanded into a coma later in July of 685 BC. Saturn, located almost twice as far from the Sun as Jupiter, was not noted until later yet, when it also developed a coma, but after Jupiter had become very prominent, or perhaps had calmed down again. Saturn thus comes last in the record because it was the last to light up.

Dwardu Cardona, in an autobiographical essay titled "The Road to Saturn" (excerpted from *Aeon*, 1988) wrote, about the revelation of Saturn as a night Sun by Jastrow:

"In the fall 1975 issue of Kronos, [Lewis] Greenberg and [Warner] Sizemore published a half-page article titled 'Saturn and Genesis.' In it they briefly analyzed Maurice [Morris] Jastrow's 1910 paper, 'Sun and Saturn,' in which the Assyro-Babylonian belief in Saturn as a sun that shone at night is discussed at some length. ... When I unearthed and read Jastrow's original paper, I became convinced that Saturn, despite the author's expected disclaimer, must have been a true sun of night, radiating its own light."

Cardona takes no account of the fact that the portions quoted by Jastrow from the *Enuma Anu Enlil* date most likely to the 7th century BC, not to the era of circa 3100 BC or earlier. I would suggest that this "sun of the night" notion was an idea surviving from antiquity, and Cardona sees it this way, but understands it as contemporaneous with the "Age of the Gods," instead of an observation dating to after 685 BC. Its use needs to be contextualized to the era in which it was written and needs to be understood as answering to political circumstances.

I think that there would be no mention at all of a "midnight sun" unless it again became relevant in late antiquity, as in 685 BC after Saturn also gained a coma, following a much more massive and visually more impressive expansion of Jupiter. Also, I do not think Saturn was the main concern of the Babylonian astrologers, but Jupiter. It was Jupiter which had lightened the skies as the "midnight sun" for a thousand years.

It seems, from Jastrow's article, that the *Enuma Anu Enlil* has nothing to do with Saturn at the pole, since by the most generous guess the data sources only date back perhaps 1000 years before 700 BC. And I even doubt that, and certainly for the data on market prices for barley. Factoids from 3400 years previous would be useless as prognostication of current conditions to the compilers after 685 BC, in addition to the fact that guessing at the future was a recent preoccupation, dating back perhaps 500 years. Almost all of the tablets deal with the Sun, the Moon, and the weather. Only the last 20 tablets deal with planets.

The *Enuma Anu Enlil* has nothing much to do with Saturn. Jupiter is indicated when "Shamash" is mentioned, and not Saturn. "Shamash" translates as "sun" from the Sumerian glyph, Utu. And Jupiter was the most recently recognized "sun of the night," not Saturn. Additionally, Jastrow is basing his "Sun equals Saturn" identity on an offhand remark by Hyginus, made 3300 years later, and on the translation of the name Shamash from Akkadian to mean "Big Steady Light in the Sky." So, Jupiter was not big and steady?

I would suggest that the astrologers of Babylon added annotations to their tablets to make sure that their notes would not be misunderstood. Shamash was the "sun of night" and understood to be the planet Jupiter. But after Jupiter lighted up in July of 685, Saturn followed suit, and started to blaze like a sun. Although this could be called "Shamash," it needed to be distinguished from Jupiter acting in the same capacity.

Jastrow says his opinions are based also on "contextual" readings. But here is the real context: The compilations were made under pressure from the Assyrians, who revived themselves in 740 BC. So we need to look at what happened after 740 BC. Certainly older records were incorporated, but not likely much further back than about 747 BC, when the skies changed. As I have noted earlier, others have pointed out that there are apparently no records for the period of approximately 750 BC to 700 BC.

Records from 1200 BC, when attention first starts being given to omens, tokens, and magical predictions, probably were not used, unless they dealt with mundane phenomena like early morning cloud cover -- if that was available at all. The objection posed by Ellenberger to the "order of naming planets" is invalidated by the fact that the "naming" followed the order of the outward travel of the nova event of the Sun after 685 BC, and has nothing to do with non-existent "records" dating back to 3100 BC. The Sumerians were not even writing in 3100 BC, and certainly were not at that time concerned with fortune telling or what the morning clouds meant.

... Mercury

No one, in the meantime, has explained the prominence of Mercury, which is almost impossible to see in today's arrangement of the Solar System. Even Jastrow writes:

"On the basis of passages like these it was natural to conclude that Mercury was for some reason regarded as the planet par excellence. I accepted this view and for the later period it appears indeed to be correct. Traces of the special position accorded to Mercury are to be seen in the multifarious traits with which he is endowed in Greek and medieval astrology. He is the only one of the planets who is conceived as both male and female and embodies, as it were, a summary of the qualities of all the planets."

If this does not date these records to being very late, what will? Jastrow takes note of the lack of physical significance of Mercury, something we know already:

"On the other hand, it was difficult to find a satisfactory reason for this supposed preeminence granted to the smallest of the planets and the one most difficult of observation, whose actual role, moreover, in Babylonian-Assyrian astrology does not at all suggest that the omens connected with Mercury had any special significance."

Is this amazing? It is also a fact that many peoples (even the Celts in Roman times, 700 or 800 years later), held Mercury in great awe. It was not only difficult to find a reason, it has proven to be impossible. No archaeologist has ever figured out the overwhelming prominence of a planet that could not be seen. Since 685 BC Mercury could almost not be found. It is only seen near the horizon just before sunrise or after sunset and only for a few days in the year. Because of this Mercury is the least significant of the planets, yet in antiquity he held a position as the God of language, magic, crafts, trades, and travel.

We know of the change which removed Mercury from the heavens. Jastrow does not, and he assumes that Mercury has always been diminutive and insignificant.

... dates

I looked by chance at an essay, "History and Science" at the University of Oklahoma, concerning the *Enuma Anu Enlil* which read:

"For centuries... [they specify 1600 to 700 BC] ..., [records were kept] because the scribes provided counsel for the king...."

Never mind the rest. They did not, not during that period, only after 750 BC or so, and then the "kings" were Assyrian monarchs, the overlords of Babylon, who would impale you if you crossed them. Where does all this claptrap come from? I get the feeling that the *Enuma Anu Enlil* has been caught up in a series of misreadings spanning 2700 years.

The records in question collate information from the past, but all offer specific data only from after 650 BC. This has long been known of the Babylonian records, although Jastrow makes the unlikely suggestion that some predate the period of Hammurabi (circa 1700 BC in the consensus chronology). In actuality, the dates do not matter, for the Babylonian astrologers were attempting to forecast events for their Assyrian overlords on the basis of desperate guesswork, using any available records whatsoever.

That, in addition to Jupiter, Saturn was also called "sun" (Shamash) is no surprise at all. Saturn indeed had been the Sun at one time -- and certainly the "sun of the night" until 3147 BC. But it was Jupiter who had been the "sun of the night" after 3147 BC and with some interruptions for a thousand years, until 2150 BC.

Some 1500 years after Jupiter had diminished in size to become a star, the Babylonian astronomers were suddenly pressed into service by the Assyrian kings, because of the destructive close passes of Mars, and then the start of the explosive nova event involving Venus and Mercury, after which Jupiter -- the night Sun -- blazed again in 685 BC, and was followed later by Saturn.

The names of the planets to be watched, which included Mars and Venus (and Mercury), were derived from a 3000-year-old tradition. In the newly developed astrological database being devised in the 7th century BC, Venus and Mars were thus named before note was made of Jupiter and Saturn -- and in that order, as Ellenberger noted.

Everyone understood that Jupiter should be called a "night Sun" if it brightened. Duplicated use of "Shamash" could be sorted out when seen in context in most cases. Some tablets, however, were annotated with indications of whether the daytime or nighttime Sun was meant, and to which planet the name "Shamash" would apply in any particular instance. Seen

in this context, the *Enuma Anu Enlil* is not a good source for suggesting that Saturn had stood in the sky as a sun before 3100 BC. It mostly speaks to Jupiter and certainly speaks only to conditions after 685 BC.

... Halos and Crowns

I think a greater fault is that none of the Saturnian commentators have done anything to address some of the truly strange wording of the tablets, like:

- "Saturn [Lu-Bat Sag-U] stands in the halo of the moon"
- "The moon has a halo around it and Saturn [Lu-Bat-Sag-U] stands in it."
- "If Shamash [(An) Ut] enters into the moon...." there is a note "Saturn (Lu-Bat Sag-U?) entered the moon".
- "When the sun [Shamash] stands in the place of the moon..."
- "When a mock-sun [Rum-me, sun-circle] stands over the moon (or) under the moon..."
- "If Shamash has a halo around it, there will be rain." with the note "Shamash of the day"
- "When Jupiter [Sag-me-gar] [stands] in the sun [An-Ut]..."
- "If Venus approaches Shamash, the King will perish." with a note explaining that here by Shamash the Sun is meant.

The essay, "Sun and Saturn," by Morris Jastrow is commentary on the translations by others, by the way. The parentheses and brackets in the quoted text above are insertions by Jastrow.

[Image: Various "star in crescent" illustrations from worldwide sources; after David Talbott.]

The illustrations above are from Talbott's *The Saturn Myth* (1980), and some might date to from before 3147 BC. The star image in that case consists of plasma streamers in glow mode connecting to Mercury (thought to be Venus) from Saturn. The left-right crescents and some other forms are missing in this collection.

Some more descriptions from Jastrow:

- A "sun-crown" above Venus...
- "Dilbat [Venus] is decked with two crowns."
- "A 'Shamash' crown above the moon, is explained as 'Lu-Bat [Saturn] [standing] by the moon.'"
- "If a mock-sun stands above the moon or below the moon..."
- "If Mars reaches the road of the sun [the ecliptic] ... there will be a famine."
- "The mock-sun and moon appear together," explained as "on this night Saturn approached (or 'was near') the moon."

The first three notes dealing with crowns need some comments from Jastrow. It is a footnote which unabashedly presents this information:

[footnote 24] *"These 'crowns' above Venus, of which various kinds are mentioned in the Anu-Enlil series -- dark, white, green, dark-red, broad, small, 'rain-bow crown', 'sun crown', 'moon crown', 'Jupiter crown' [reference deleted] -- clearly refer to rays above Venus, the different colors being ascribed to different planets standing in front of her, green = Mars, dark-red = Mercury, while other designations, similarly, describe the supposed specific causes, a 'rain-bow' crown being due to the rain-bow, a 'moon' crown to the moon etc."* [reference deleted]

Jastrow justifies the texts of the tablets in uniformitarian terms, as with:

"Strange as it may seem to us, the planet Saturn appears to have been regarded as 'the sun of the night' corresponding to Shamash as 'the sun of the daytime' and the cause of such light as the night furnishes. It was argued, that since there was a sun furnishing the light of day, so there must be some corresponding power which causes the illuminations of the heavens at night."

It is difficult to conceive of a more patronizing attitude toward the "magicians and astrologers" of Babylon. To think they reasoned that there "must be" a Sun of the night, is to assume that they were no brighter than 6-year-old children.

... refraction

Besides the fact that such absurd reasoning degrades the intellectual abilities of the Babylonians, this supposition (and others about "atmospheric phenomenon") is not necessary.

The "crescent of the Moon," seen below, above, even on both the left and right, or seen in multiple units, plus the various colors, is the diffraction of the light of a very bright planet on approaching the last remaining band of the equatorial rings. This had been the case since 2349 BC when the Absu disappeared, but only at this time, at the press of the Assyrian kings, was it necessary to compile all available data and try to make sense of it.

The refraction pattern would be placed some distance away, probably $1/4$ or $1/2$ wavelength of the striations, and thus perhaps $1/4$ spherical degree to the left and right, and make it appear as if the planet were placed within a Moon. Mesopotamian "Star and Crescent" images show the star consistently well within what would be the orb of the Moon, a situation which could not happen if the crescent genuinely belonged to the Moon. The above and below crescents of the moon (a waxing or waning Moon in the first quarter or last quarter) only happen in the tropics.

The left and right diffraction, when a bright object was centered on the band of the remaining equatorial ring, would result in an image similar to the "double axe" image of remote antiquity, but on a somewhat smaller scale. Before 2349 BC the ecliptic dipped behind the intact Absu. Jupiter, with its gigantic coma, would at that time have been the candidate for the giant double axe imagery (known traditionally as a "labrys"), refracting its bright disk to the left and right as giant crescents. The refraction of light would be predominantly to the left and right because the structure of the rings of the Absu had a radial component (described in Egypt as "reeds"). The handle of the labrys axe, which is infrequently shown, is always too slim to be hafted to a large double-bitted axe head. The labrys is a ceremonial object of the Middle Bronze Age, circa 3200 BC to 1200 BC.

I should point out, however, that images of a star within an upturned crescent could date back to before 3147 BC. At that time the crescent at the bottom was the Sun-lighted lower half of Saturn. The star form consisted of plasma in glow mode impinging on Mercury in discrete bundles. Like the dark of the Moon during the day, the unlit portion of Saturn would not show up visually during the day. But the identification of specific planets in the *Enuma Anu Enlil* records argues against the notion that such imagery dates from before 3147 BC.

It is the same diffraction of any point-source light of a planet or star when behind the last of the equatorial rings which causes the depiction of planets as four- and eight-pointed figures. The refracted light would be at right angles to the pattern of the equatorial ring. Refracted light would radiate left and right from the primary planet behind the ring. If the ring had a granular structure the refracted light would more likely form a "halo." Photographers use filters with etched lines to achieve similar effects.

The use of the phrase "mock Moon" implies that the Chaldeans recognized that some of these images were not real. But they were signs in the sky, and had to be accounted for.

Jastrow and others allowed that the situation of Saturn, or another planet, might be seen above or below the Moon because the Moon frequently runs off the ecliptic by some 5

degrees. What has not been accounted for, of course, is to have the Moon's crescent appear on the top or bottom. That does not happen in real life except at the horizon in the tropics.

It should also be pointed out again that the last equatorial ring was red. It caused Sirius to appear as red when the axis of the Earth shifted. The ring was recalled as a rope in the sky by the lowland Maya -- "and blood ran through it." In the *Popol Vuh* it is called the "river of blood." This is the Uroboros. The tablets, on the other hand, suggest many colors.

The patterns would appear where the ecliptic crossed the ring in the sky. Because the ring was located in the south below the equatorial, these events would not happen directly at the equinox location (the intersection of the equinox and the equatorial), but would have been a month or so later in fall and earlier in spring.

... Saturn in Pisces

What needs to be answered also is why the *Enuma Anu Enlil* has so much to say about Saturn. Obviously Saturn was seen frequently, and seen in a position in the sky which caused the strange appearances of "standing in the halo of the Moon."

In fact, let us consider Saturn for a moment. Saturn moves at such a slug-like pace that it is unlikely that anything interesting would ever develop in terms of its interactions with other planets. It takes 30 years to get around the zodiac, moving only 12 degrees per year.

What would make Saturn more interesting would be the occasion for it to be seen through the last remaining band of the Absu. Then it would twinkle and sparkle and cause refracted patterns. I decided to research this topic.

The orbit of Earth had stabilized in 747 BC, and since Jupiter had last blazed in 2150 BC, it could be assumed that Saturn had also come to its final orbital position a thousand years ago. Thus an ephemeris would be accurate for the time period after 685 BC (the last change in celestial parameters). It would work if Saturn would travel through the location of the last ring in its travels along the zodiac.

Well, it turns out that in the fall of 685 BC (astronomical year), Saturn is on the zodiac at an elevation (at its highest point in the night sky) of 45 degrees at Babylon, 12.5 degrees below the equatorial. This places it within the last ring of the Absu, and thus it would be seen behind an ever-changing curtain of particulate matter, causing refractions left and right and below.

This depends, of course, on my estimates of how high in the sky the last ring of the Absu appeared. I have made some estimates of this in an appendix, on the basis of numerous reports of Sirius as colored red. The data is from the current era, and spread from AD 200 to AD 570. In each case Sirius is at a declination of 16.5 to 16.0 degrees below the equatorial.

In September of 685 BC Saturn was at 12.5 degrees declination below the equatorial. A width of 4 degrees is reasonable for the remnant of the Absu.

The Moon would move through this position frequently, as would the other planets. Saturn would move away from this location in a few years, after having spent more time behind the last ring of the Absu than any other planet. Jupiter would move into this location three years after Saturn, but Jupiter had already blazed earlier, starting in July of 685 BC. The red ring is, of course, the Uoroboros.

Thirty years later, in 655 BC (astronomical), Saturn would again spend some years moving through this position. And again in 625 BC. In 612 BC (in normal Eastern Mediterranean chronology) the Persians and Medes burned down Nineveh, the capital of the Assyrians. With that the astronomical records of Babylon ended.

I do not think these last two instances would have added anything to the record which was probably originally composed directly after June and July of 685 BC, for it seems 655 BC and 625 BC are much too late for a planet to still show a coma after the event of 685 BC. What we see instead is a long record all dating to the many months that Saturn had traveled through the path of the red ring in 685 BC. This would account for the many records concerning Saturn.

New Star Charts

What is also significant is how graphical star charts changed. Before 600 BC the constellations are depicted as seen from the vantage point of Earth. There was no other imaginable point of view. After 600 BC we start seeing reversed charts, and eventually globes, which require a vantage point from outside of the dome of the stars.

In time, the more subtle changes in the sky became public knowledge. It was of special significance because for most people the Earth was fixed in space, and it was the dome of the stars that revolved. The dome had been twisted and the axis had relocated. The effect of knowing that *there had been a change* in the dome of the stars would have been of much greater importance than any physical effects from the actual change. The change suggested a prime mover acting beyond the largest object in the Universe known at the time, the dome of the stars, which included all the planetary Gods. The concept of an entity which could alter the whole Universe eventually formed the basis of most religions of the world. That this had happened in one 40-day period of a summer, accompanied by planets on fire in the sky and then disappearing, was important also.

The Sibylline Star Wars

The *Sibylline Oracle Books* are texts from the first century AD, composed in Alexandria, Egypt, in Greek. The last few lines of the fifth volume, known as the "Star Wars" text,

describe the blazing of Venus in 685 BC and the change in the skies -- written nearly 800 years after the event. These lines prophesied the future or impending end of the world in terms strictly coincident with events of 685 BC. It is probably the most spectacular evidence of the religious and philosophical importance of the events of 685 BC.

Oracle Books were all the rage in the period of 100 BC to AD 400. John's *Book of Revelations* is an example of one which was accepted into the canon of the New Testament. Oracle books, or collections of visions and oracles, date back to perhaps the fifth century BC. The Roman senate employed a number of persons as keepers of *Roman Oracle Books*. They were consulted whenever difficult decisions arose. [\[note 2\]](#)

The *Sibylline Oracle Books* are mostly Jewish in sentiment and philosophy. They use a well-established metonymical style (substituting associated names, like "Babylon" for the Roman Empire) used by the oracle of Delphi and the prophets of Israel. A close examination establishes without doubt that the descriptions can be matched against the changes in the skies in 685 BC, not only in the movement of the planet Venus, but especially in the details of how the constellations were rearranged after a new equatorial was established, and all of it presented in poetic language. Franz Xavier Kugler examined the Star Wars text in 1927. This has been expanded upon by Malcolm Lowery and Livio Stecchini in the 1970s. An analysis, additional details, and diagrams may be found in the following chapter, "The Sibylline Star Wars."

Hezekiah and Babylon

There is a well-known promise delivered by Isaiah from God to Hezekiah, king of Judah, in about 690 BC (probably in early 684 BC). Hezekiah was sick and thought he would die. Isaiah agreed, but the same day changed his mind and told Hezekiah that he would live another 15 years. As a sign, God promised the following:

"And this shall be a sign unto thee from the Lord, that the Lord will do this thing that he hath spoken. Behold, I will bring again the shadow of the degrees, which is gone down in the sun-dial of Uzziah, ten degrees backward. So the sun returned ten degrees, by which degrees it was gone down."

-- Isaiah 38:8

It was a rash promise, but it can be explained. Velikovsky, in an unpublished document (hezekiah.htm at <http://www.varchive.org>), suggests that "degrees" should be read as such ("*maaloth in Hebrew is preferably 'degrees' and more so when applied to the sundial*"). Donald W. Patten and Samuel R. Windsor, in *The Mars-Earth Wars* (1996), however, disagree and suggest it should be taken to mean "measure." I also doubt that the "ten degrees" can be understood in terms of degrees of a circle as today. We are in an era 800 years before the development of trigonometry and the measurement of "degrees." Ussher makes the point

in his comments that Judah was not even using "hours" to measure the day, even after their return, much later, from Babylonian captivity.

Patten and Windsor place the "commotion of Uzziah" in 756 BC, and the "return of the shadow" in 701 BC. De Grazia places the commotion in 747 BC (-747), as does Velikovsky. Velikovsky places the return of the shadow in the year -687, on the basis of rabbinical sources, in the evening of the demise of Sennacherib's army. The rabbinical sources, however, only point to a disturbance in the movement of the setting Sun. We know about that. In -687 Earth experienced a repulsive electric contact with Mercury, detailed in the previous chapter.

If, as Isaiah suggests, the "ten degrees" were added earlier, then it might be suggested that the Earth's axial inclination to the normal of its orbit changed from some previous value and returned to 23.5 degrees in 686 BC, with the second Earth shock. I really doubt this. But the implicit suggestion of a previous event which would have moved (lengthened) the shadow, is exactly what all the catastrophic researchers from Velikovsky to de Grazia were looking for. There was no "commotion" to account for this; the reference to Uzziah is a foil. Uzziah only built the gnomon, "the sun-dial of Uzziah."

What is most likely is that the promise by Isaiah speaks only to the measured length of the shadow at the equinox. Before 685 BC the equinox fell 15 days earlier than after 685 BC, as I have related. On this earlier equinox date, March 6th, the Sun at noon reached an angle of 58.38 degrees above the south horizon at Jerusalem (31.78 degrees north latitude). After the summer of 685 BC, the Sun was lower in the sky on the following March 6th, rising only at 52.34 degrees above the horizon, and causing the shadow to be longer by a good measure on this day.

The first full moon after the equinox had traditionally signaled the celebration of Passover (on the following Sabbath). Thus it was important to know when the equinox was. This could no longer be found from the lunar calendar as in the era before 747 BC, but it could be calculated from the number of days since the last equinox and checked against the length of the shadow on that day.

But in the first year following 685 BC, the angle of the Sun at noon on March 6th was only 52.34 degrees above the south horizon. The shadow had (as a result) lengthened by one fourth of what it was earlier. This is a considerable amount, and reason enough to call it "ten degrees" or ten measures. The Sun, on what was thought to be the day of the equinox, had "gone down" some large amount. [\[note 3\]](#)

There was no event which returned the shadow to its proper length, only the realization by Isaiah that the day of the equinox had moved (remember, he had changed his mind). Isaiah's promise held good, because 15 days later, when the "new" day of the equinox was reached, it was again 58.38 degrees, or very close to it. The shadow on March 21, 684 BC, was again the same length that it was on March 6, of the previous year, for the angle of the Sun at the

equinox depends only on the latitude, not on the inclination of the rotational axis of the Earth. Isaiah had experienced the change of the date of the equinox already in the fall, and could have made the simple guess from that data. Isaiah, like many of the prophets, was a competent astronomer.

What is interesting is that the sign from God also symbolized how many more years Hezekiah would live, for the difference between the old day of the equinox and the new date was 15 days. This is not mentioned in the Bible, but it is in line with the frequent acting-out by the prophets, as when Isaiah goes naked and shoeless for three years to demonstrate what would happen to the Egyptians after a three-year war with the Assyrians. *"This intimated that when that time expired, they likewise would be stripped of their clothes and go bare foot into captivity and bondage by the king of Assyria."* -- Ussher.

... Jerusalem moves 6 degrees south

Another discrepancy in the 7th century BC is noted by Donald W. Patten and Samuel R. Windsor in *The Mars-Earth Wars* (1996). The priests of the temple at Jerusalem permanently close the door through which, at an earlier time, the rays of the Sun would penetrate to the center of the temple on the morning of the equinox. Patten and Windsor conclude that Jerusalem moved south by 6 degrees of latitude in the 8th or 7th century BC, writing:

"On the basis of Kazmann's data [Raphael G. Kazmann, 'On the Orientation of Ancient Temples and Other Anomalies' (Aeon, 1990)], the conclusion here is that the latitude of Jerusalem slipped south by a total of 6 degrees between 965 B.C.E. and 701 B.C.E. During this time span there were five Mars flybys."

The date of 701 BC is, of course, from Patten and Windsor's narrative. The date of 701 BC marks, for them, the date when the length of the year changed -- which every other revisionist cosmologist has assigned to 747 BC. Patten and Windsor therefore conclude that the temple doors were closed after a change in the length of the year. The first temple, attributed to Solomon was oriented to face the northwest Atlantic. The light of the Sun was cast into the interior with a set of mirrors.

"If this interpretation of Kazmann's data is correct, the latitude of Jerusalem shifted southward by some 400 miles. Simultaneously the North Pole (spin axis) shifted some 400 miles in the Arctic Basin. If so, the North Pole net shift was away from Scandinavia and toward Alaska, the Yukon, British Columbia (and Seattle). As Jerusalem shifted southward 6 degrees, or 410 miles, Seattle, Vancouver, Anchorage, Fairbanks and Point Barrow shifted northward a similar distance and their climates became cooler."

I frankly cannot follow how Patten and Windsor arrive at the difference of 6 degrees in latitude. Moving a location south (or north) does not change the shadows at the equinox or the location of the rising Sun. The first temple at Jerusalem had an axis located 6 degrees

west of north, pointing to the North Atlantic -- to the much earlier location of the plasma contact from Saturn.

Patten and Windsor fail to note that the temple built by Solomon was rebuilt in 516 (after the Jews' return from Babylon) but oriented to the true north-south and east-west cardinal directions. I might suggest instead that the sudden displacement of the equinox by 15 days in 685 BC and the change in the polar axis might have been an influence in correcting the notion of orientation which was already 2000 year out of date in Solomon's time.

... the latitude of Babylon

It was noted in antiquity that apparently the latitude of Babylon had shifted by about 2.5 degrees south, from 34.95 degrees north latitude to 32.55 degrees latitude, some time after 700 BC or 650 BC. That there were two values for the geographic location, that is, the latitude, of Babylon, which could be derived from recorded measurements of the longest day at midsummer, was noted by Ptolemy (circa AD 150), Arzachel (circa AD 1050), Kepler (circa AD 1600), and Kugler (circa AD 1910). The records date from 700 to 650 BC. Kugler worked from original sources.

However, there was no change in latitude; it was an inadvertent misreading at the time the inclination of the Earth's axis changed.

In antiquity the "latitude" was expressed as the ratio of the longest day to the shortest day, and rather poorly integrated into notions of the angle of the Sun and the inclination of the Earth's axis. Babylon's "earlier" recorded ratio of longest day to shortest day was 1.50.

We cannot solve this problem with trigonometry as we know it, for trigonometry dates from about AD 300. The Babylonians, similarly, would not have used trigonometry.

The latitude problem has remained unexplained for over 2000 years now. What I will suggest as a solution is that the ratio of 1.50 was erroneously derived. The following is based on how the Babylonians would most likely have proceeded.

The first date after July 25, 685 BC, that new values would be measured, would be the winter solstice. This is easily found, since the Sun would seem to be standing still, that is, not advancing along the horizon, for two to four days.

The length of the day was 9 hours and 50 minutes. Taken into a ratio of the longest day at the previous summer solstice (at that time on June 6th, equivalent to June 21 of today), 14 hours and 52 minutes, which had occurred before the change in the heavens, this would yield 1:51 - and was recorded.

axial incl	longest day	shortest day	ratio	notes
30.0 deg	14:52 hrs	9:06 hrs	1.63	prior
23.5	14:08	9:50	1.44	today

measured Dec 685, compared with Jun 685:				
30.0 deg	14:52 hrs			Jun 685 BC
23.5		9:50 h		Dec 685 BC
error	14:52	9:50	1.51	in error

measured Jun 684, compared with Dec 685:				
23.5	14:08			Jun 684 BC
23.5		9:50 h		Dec 685 BC
correct	14:08	9:50	1.44	correct

Six months later a new ratio of 1.44 was computed, based on the new lengths of both the winter and summer solstice.

Had the Babylonians known trigonometry, they would have realized that the latitude can be found as the complement of the height of the angle of the Sun above the south horizon at the equinox. Without this, the Babylonians had to use the solstices to properly measure the shadow.

Considering that the Babylonians were deeply involved in their revised mathematics of lunar eclipse predictions, and additionally kept multiple records of the locations of the planets, even though some were obviously outdated, it seems reasonable that an erroneous value for the ratio of the longest day to the shortest day was also not discarded. That was a mistake.

Whatever happened to the ratio of 1.63 recorded before 685 BC? It was based on a polar axis tilted at 30 degrees, taken into a ratio based on the current axial inclination. It is not just wrong, but even useless. This ratio would have suggested that Babylon was located at 40.3 degrees north, a difference of 7.75 degrees, placing Babylon in the Caucasus mountains between the Black Sea and the Caspian. No one since Babylonian days would have believed that, and if this value had been recorded it would have been held as totally erroneous. Even the Babylonians of the seventh century BC would have discarded the data.

The additional erroneously derived ratio of 1.51 was kept because it looked to be nearly correct. The Sun had moved in 685 BC, that was certain. Who was to tell how things had changed with the Earth and the stars. Pliny had described it as "a slackening of creation," as if the Earth had slipped south.

... the Babylonians visit Hezekiah

The Moon had changed its period after 747 BC, to 29-1/2 days, and thus there were now slightly more than 12-1/3 lunar months in the year, since the year had also lengthened. This would cause no end of problems, for the lunar months no longer coincided comfortably with the number of days in the solar year. But after the summer of 685, there was the additional problem that the equinox had shifted.

As a comment on cooperative calendrical efforts in the Middle East, it should be noted that the Babylonians (Chaldeans), who had apparently celebrated the new year at the spring equinox based solely on the fact that this coincided before 747 BC with a new Moon, were now at a loss to figure out the date of the equinox, especially since the phases of the Moon now showed up at arbitrary times throughout the year.

Babylon sent observers to Jerusalem, for the Israelites knew the day of the equinox, since Passover was celebrated on the Sabbath following the first full Moon after the spring equinox. Jerusalem knew how to exactly find the day of the equinox, by counting days, and by measuring the shadow of a gnomon. The visit by the Babylonians is recorded in the Bible at 2 Chronicles 32:31.

William Whiston, translator (in AD 1737) of Josephus's *The Antiquity of the Jews* (AD 93), writes in a footnote, about the regression of the shadow of a gnomon by ten steps under Hezekiah (in 685 BC):

"... this wonderful signal was not, it seems, peculiar to Judea, but either seen, or at least heard of, at Babylon also, as appears by '2-Chronicles' 32:31, where we learn that the Babylonian ambassadors were sent to Hezekiah, among other things, to inquire of the wonder that was done in the land."

Ussher records this as:

"Now in the beginning of the 15th year of Hezekiah's reign, Merodach, or Berodach Baladan, the son Baladan, the king of Babylon, sent messengers with presents to him. They wanted to know the reason for the miraculous retrogradation of the sun which happened in the world."

The "retrogradation" is correct nomenclature. The Sun normally advances in the sky further east each following day, and further into the series of zodiac houses. What had happened is that the Sun had backed up half of a zodiac house, as noted by the end of the year 685 BC. We have to recognize (as has already been demonstrated in this text) that the prophets of Israel were competent astronomers. This is again demonstrated here, where the foremost astronomers of the whole Middle East come to Jerusalem to learn a few things.

Philosophy, Religion, Science

Venus lost its tail in 685 BC, and Mars no longer came close to Earth after 670 BC. Mercury also was not seen again anywhere near Earth. The coma of Jupiter had probably disappeared by 650 BC. The blackboard in the sky, which had taught mankind all of its conduct, had been erased. The Gods were gone. When Xerxes, in about 484 BC, entered Babylon to destroy its religious hold on the region, he found the statue of Marduk in a coffin. He melted it down.

Despite some continued local "Ignis Coelis" (fire falling from the skies), continued sightings of meteors, which slowly reduced in frequency over the next 1000 years, and the earthquakes which continued for hundreds of years, the lessons from the Gods had come to an end. In the sky only the stars and pinpoints of planets were to be found. The band of the ecliptic continued to glow like a highway until AD 1840. In the 20th-century, references to the "path of the Gods" are identified with the Milky Way instead (to confound "ancient legends" even further).

[Image: A 19th century graphic in the style of a medieval illustration by Camille Flammarion (1888); looking past the dome of the stars. Rather than finding God beyond the dome of the stars, the viewer is confronted with an endless expanse of additional wheels and gears -- the mechanics of the Universe.]

Yet plasma contacts between distant planets persisted for a long time after 670 BC. There are dozens of recorded observations in China, Arabia, and medieval Europe. Charles Raspil paraphrases an incident recorded in China in the 10th century AD, which caught my eye:

"On the morning of March 18, [AD] 904, Venus was observed near the Pleiades blazing like fire. The next morning, to observers, Venus appeared to have developed three horns, somewhat resembling a flower, and then began to tremble and shake.

-- Charles Raspil *Planetary observations of the T'ang* (1994) [\[note 4\]](#)

Mars and Jupiter are also noted for anomalous behavior, but many of the observations find the planets in the wrong location, and thus the anomalies can be attributed to errors in identification. Strange celestial events were frequently noted elsewhere also, as recounted in European records of "fire falling from heaven." But humanity was no longer confronted with large globes looming threateningly above the Earth during the day or night. After 685 BC the planets kept their distance.

The planets, which had previously had been seen as the Gods -- Saturn, Jupiter, and Mars -- had been identified and tracked as they receded in the sky after 3147 BC and after 685 BC.

But Venus was not added to the "four planets of antiquity" until after 600 BC -- primarily because of the strange path taken by Venus in the sky. And, in fact, the clear identification of Isis, Horus, and Thoth with the planets Venus, Mars, and Mercury often remained uncertain during the prior period when the Gods raged across the skies.

They were often misnamed and misidentified, confused with each other, or associated with the names of differing Gods and Goddesses (and stars also). This was to be expected since the planets were on unpredictable orbits, disappearing towards the Sun or deep into the night sky, and then appearing inexplicably close to Earth. As long as that happened, and as long as no "model" of the Universe existed, the planets retained their anthropomorphic qualities. A science of astronomy, based on the regular traversal of wandering specks across the night sky, did not develop until after the 7th century BC. [\[note 5\]](#)

The suddenly cleared skies caused a second immense change in humanity's perspective on the world, not unlike the change in 3147 BC when the Gods departed, but without the attendant catastrophic physical trauma. Whereas for 10,000 years everything had been ordered by the willful and unpredictable Gods, now there was nothing to base life's decisions on.

The New Religions

We can readily trace the development of all of the modern religions to the period following 685 BC, although many have much deeper roots.

... Zoroastrianism

In the seventh and sixth century BC, Zarathustra (born in 628 BC, a date derived in antiquity), a Persian, develops a new religion, Zoroastrianism, as a composite of Vedic and Persian religious practices. He retains the essential monotheism, equating the deity Mazda or Ahura-mazda with fire, and adds prohibitions against human and animal sacrifices. He is also the first to suggest the devil as a separate God, forever in conflict with Mazda for control of the world. Zoroastrianism becomes the official religion of the Persians. It is significant not only for its monotheism, but also for the change of worship from anthropomorphic celestial deities to a worship of a conceptual God, here expressed as the element of fire.

Philosophically, Zoroastrianism introduced the concept of free will. It seems almost certain that Zoroastrianism had been influenced by the fiery battle of Venus and the Sun.

... Mithraism

One of the (later) minor deities of Persian Zoroastrianism, Mithra (which translates as "contract"), becomes the God of a new religion and contract between humans and a greater God. The concept of a covenant between this new, greater, and impersonal God is offered as

a promise of hope, something which will pervade all the new religions except Taoism.

[\[note 6\]](#)

Mithraism was first noted in Parthia in 272 BC and became well established in Roman regions of Europe and North Africa by the first century AD. In a few hundred years, Mithraism spread far into Western Europe as a self-contained religion. It was a forerunner of Christianity, especially in the idea of a "new contract" between God and mankind. In the Roman cult of Mithraism, the name "Mithras" is understood to mean "mediator." Christ preached a new contract with God also, under the metaphor of God as a shepherd.

Mithraism takes on the iconography of a bull (the constellation Taurus) slain by the God Mithras (as represented by the constellation Perseus, standing above Taurus in the sky), and clearly includes a number of other constellations in the imagery. These are constellations close to the equatorial, not the ecliptic. All represent animals which one by one follow Taurus in appearing above the eastern horizon during the summer night skies.

"In Porphyry [philosopher, 3rd century AD], for example, we find recorded a tradition that the cave which is depicted in the tauroctony and which the underground Mithraic temples were designed to imitate was intended to be 'an image of the cosmos.'"

-- David Ulansey *The Origins of the Mithraic Mysteries* (1989)

The cave as a metaphor for the cosmos is an interesting concept, for this can be extended to having a God standing outside of the cave, outside the cosmos. We have no clear idea what the real meaning of the Mithraic iconography is, although it could be guessed that it expressed a new order for humanity and the Universe: the old gods were dead, the Son of the Sun (Venus in 685 BC) had slain the horned bull (Taurus) associated with the former Gods (and the prior start of the year), and had moved the whole sky to a new starting point for spring -- to the constellation of the Ram. The understanding was that the start of a new world order had been signaled with a sign from a God who exceeded in power all of the old deities, a God who stood outside of the dome of the stars and planets and suddenly moved it one day to a new location. [\[note 7\]](#)

We need to add another set of twins to the list developed in the previous chapter. The iconography of Mithraism always includes twin boys (known as Cautes and Cautopates) on the left and right of Mithra and on each side of a surrounding depiction of the zodiac. The boys are holding torches, one holds his torch high and one with his torch pointed down. Both boys have their legs crossed, each with a different leg in the front. Others have noted that the crossed legs might represent the vernal and autumnal equinox -- the St Andrew's cross of the red ring of the equatorial and the yellow band of the ecliptic, as I had also noted for Mesoamerica. In some cases the crossed legs correspond correctly to the the vernal and autumnal equinox, in other cases these are reversed.

I would also suggest that the torch held down and the torch held high represent the winter

and summer solstice of the Sun respectively after the fall and spring equinox. The torch held down represents the act of relighting the torch at the winter solstice (which is normally done by grinding the lighted end against the ground). The torch held high represents the full light of the summer solstice (they might represent the equinoxes instead of the solstices). [\[note 8\]](#)

... Taoism

In China, Lao-tse (604-531 BC) develops the philosophy of Taoism. Lao-tse's book, the *Tao-te*, proposes to explain "the change of the path." The path, which could metaphorically be taken as "the path of life," is clearly also the path of the planets. Chinese cosmology had already advanced to imagine the Earth (although conceived of as a flat square of land) surrounded by a rotating dome of the stars. The shift in the heavens in 685 BC must have had a huge impact on the thinking of the Chinese. It was as if some giant external hand had suddenly twisted the dome of the stars. This seemed to have curtailed any further removal of the remaining "mystical" elements from religion and cosmology which had been initiated by the Chou. The power of a "heaven" was retained as a certainty, as an external force which would continue to dominate imperial politics, reinforced by later Confucian philosophy. [\[note 9\]](#)

We have to understand the "new religions" as having the same purpose as the "new philosophies" (discussed further below). Both sought a moral order independent of the older Gods, and both were meant to democratize thought and religious practices, in effect taking these functions away from a priestly cast. The coincidence of dates is as follows:

- Zoroaster (Zarathustra, Northeastern Persia, 628-?? BC), of the tribe of the Magi, developed Zoroastrianism (Mazdaism). Zoroaster understood the events of 685 BC as a battle between good and evil, with good eventually winning the battle, but not without continued support from the people. The Persian kings hired the Magi to officiate at their ceremonies and sacrifices. The monotheism of Mazdaism influenced Judaism during the Babylonian captivity of the Jews (597-536 BC), and spread throughout the eastern portion of the Middle East and into Arabia. It gave rise to Mithraism by perhaps 300 BC, and was a very important model for Christianity and, at a much later date, for Islam. [\[note 10\]](#)
- Lao-tse (China, 604-531 BC) devised the philosophy of Taoism. His existence may be in doubt, but that would serve his philosophy of restraint well. Taoism was discussed above.
- Confucius (China, 551-479 BC) extended to everyone the worship services originally only allowed to the emperor.
- Siddhartha Gautama, the Buddha, (India, 563-483 BC) founded Buddhism, one of the major influences in the reformation of Hinduism, and later a major philosophical influence in China. About the teachings of the Buddha, H. G. Wells, writes in *The Outline of History* (1961), "*It is beyond all dispute the achievement of one of the most penetrating intelligences the world has ever known.*"

- Vardhamana Mahavira (India, ??-527 BC) was the founder of Jainism, with ideas partially derived from Hinduism and Buddhism.
- The mystery religions of Anatolia and Greece (the worship of Demeter, Orpheus, Dionysus) all seem to date to the 6th century BC, although some elements, as, for example, the Eleusinian rites of Demeter, may be much older and more primitive. [\[note 11\]](#)
- Changes in Mesoamerica are harder (if not impossible) to trace. The Olmecs seemed to have worshiped (or feared) Mars in the 8th and 7th century BC (and Venus earlier). Elements of their culture resurface in Central Mexico, but with the addition of the cult of Quetzalcoatl, the sacrificed Venus, and a cult of the dead -- actually a cult of the afterlife. New alignments to the setting or rising sun on or about August 12 become a feature of ceremonial centers after 600 BC. The definitive site was the city of Teotihuacan -- "the place where men become Gods." See the chapter "Olmec Site Alignments."

The new religions were testaments to hope -- hope for a good life on Earth, hope for the abatement of evil, hope for an afterlife, hope for union with God, hope for victory of a nation, hope for the conquest of others. The specifics vary with the politics and philosophy of various peoples. The Christians hoped for the return of their savior. Their hope lasted 1200 years. The Mexicans and Maya hoped for the return of Quetzalcoatl for 2200 years. The promise of a redemption resulting in life after death is almost universal.

I should also point out that the older Gods were not simply put aside. From a look at the history of republican and imperial Rome it becomes obvious that, certainly at the official level, the honors and ceremonies extended to the elder Gods continued unabated for the next thousand years. But it should also be noted that no new Gods were added. As Alfred de Grazia wrote:

"No new sky god has been 'invented' in any part of the world since the Martian age [after circa 680 BC]. ... Nor did the Teutonic peoples invent new gods, try as they might, after the 'Ragnarok' or 'Götterdämmerung.' Nor did a new sky god come out of India, China, or America."

"Whence one concludes that 'real gods' cannot be 'invented' by the human mind as a pastime, or as a cold decision. Further, the abstract God of the Jews and of Christians and Muslims, and the abstract Heaven of the Chinese, are gods of philosophy. Insofar as a tangible presence is given to them, that presence becomes manifest in the behavior, appearances, visitations, rituals and iconography of the ancient sky gods and their heavenly hosts."

Philosophy and Science

Within 100 years after 685 BC, we see the simultaneous rise of philosophy in China, India,

Mesopotamia (Chaldea), Israel, and Greece. The coincidence of start-up dates is amazing. The methods of building a philosophical system differ, but everywhere the systems include a sudden interest in history and in physics. About the sudden interest in materials and basic concepts, Kelley L. Ross writes:

"The multiple points of similarity between thought of Greece, India, and China, evident in the simplest terms in their respective treatment of the physical elements, cannot be accounted for by mutual influence, which does not seem to have existed at the earliest period." [\[note 12\]](#)

China will retain the Yin and Yang and the "five elements" of remote antiquity, and build onto this a political and moral philosophy. Chaldea and India devise a science of astrology. Israel collates the historical facts for the Bible and adds the rituals from antiquity. The Greeks start investigations which will form the core of Western physics, and write the first histories. [\[note 13\]](#)

About the period of 600 to 500 BC, Irving Wolfe wrote, in 1997:

"[There is] evidence for what I call a 'Kultursturz' or cultural crisis in which a large number of cultural elements underwent quick and sharp change within the same short period of time. These include the appearance of secular as opposed to strictly religious art, a host of new religions of a new type, new philosophies of a new type, writing, dynastic upheavals, the quick upsurge and removal of several tyrannical regimes, urbanism, new patterns of consciousness, behavior, and dreaming, new types of social organization, vast pan-Greek ritualistic athletic games, the institution of democracy and the use of money. All of these elements are totally different in spirit from those of the previous (Bronze Age) cultures."

-- Irving Wolfe, "The 'Kultursturz' At The Bronze Age / Iron Age Boundary" *Natural Catastrophes during Bronze Age Civilizations*, SIS Conference (1997).

Wolfe continues with:

"If all of these cultural revolutions can be correlated chronologically among themselves and to scientific evidence for similar upheavals well documented in the geological, archaeological and climatological record, then we have before us the outline of a global natural event which not only ended one historical era, but led to the distinctive cultural characteristics of our modern age. After all, we are the children of this period of upheaval."

The "evidence for similar [geological] upheavals" clearly exists as part of the 8th and 7th century BC, preceding the changes of the 7th and 6th century BC which Wolfe speaks of. But the one single celestial event of 685 BC, which became the definitive opening of the new human cultural era, caused no physical upheavals.

The people of Mesoamerica also acknowledged the change in milieu, even though the written records attesting to this do not appear until nearly 2000 years later. The death of Quetzalcoatl is a concluding event in Mesoamerica, as it was for people elsewhere in the world, and no new celestial Gods are introduced after the 7th century BC. It is at this time, in fact, that we see the demise of the Olmecs and the rise of other Central American civilizations, and a Mesoamerican "physics" which becomes a system of control over the spiritual world, not unlike that of India and Babylonia. An intense interest in history also develops, soon aided with a fully developed script (after 600 BC) used to elucidate the much older graphical records painted on bark books. The interest in history at this time was worldwide.

"And here ends that interval of time which is termed mythological. From this time on history begins."

-- Varro, first century BC.

Varro is actually speaking about history after the 8th century BC, in reference to 776 BC, the first Olympiad. But prior to Varro Greek chronographers had already divided history up into two eras, the "mythological" and the "historical." The year 747 BC was the dividing line between the two eras. [\[note 14\]](#)

By the first century AD, historians are convinced that there is no sensible history more than a few centuries before their own time. Varro and other historians had never seen any of the wonders that the ancients talked about, nor had Herodotus in 400 BC. They considered the visits of Athena, streaking through the day skies with her long hair, or the attacks on the Earth by Ares, the bloodied stormer of walls, as "myths" concocted by their ancestors. Their attitude seems entirely modern to us. In the Greek city of Miletos, a new school of philosophy sought to explain the world in terms of what was observed rather than basing explanations on the testimony of the ancients. [\[note 15\]](#)

"Human beings are distributed all around the Earth and stand with their feet pointing to each other"

-- Pliny, first century AD

Pliny's observation is paralleled by Greeks, Mesopotamians, Indians, and Chinese of the same era. "Everywhere upon the globe of the earth, men think their own place to be topmost," reads the Hindu *Suyra Siddhanta* of about the same date. Many people of this era knew that the Earth was a globe which "hangs suspended and does not fall," as Pliny wrote. Chaldeans knew that eclipses of the Moon were caused by the Earth's shadow, and could predict them. Aristarchus of Samos knew the Earth traveled around the Sun. Hipparchus (129 BC) calculated the minute annual shift in the Earth's equinox. Eratosthenes correctly found the circumference of the Earth. [\[note 16\]](#)

I am using these examples of a new physics of the Solar System to demonstrate that a

watershed had been reached in subjective consciousness, which over the course of a few hundred years expands to an ability to incorporate observations into narratized mental spaces and explore them profitably. This particular model -- representing the Earth as a globe suspended in space -- could only be seen in the imagination.

The same is seen in China and India at about the same time, where natural history develops into "sciences," which depend on imagined mental spaces congruent with reality as observed. To explain everything, without reference to remote antiquity, it was first necessary to describe the physical world.

Not the same can be said for Mesoamerica at first glance, with its detailed congruence of real-world and spiritual-world interactions, based perhaps too much yet on the celestial observations of remote antiquity for our taste. But there was also a very different attitude toward the past. The people of Mesoamerica had complete illustrated records of the past, extending back 40,000 years, and in a uniform graphical format. Pictures don't lie; the Olmecs, Mexicans, Guatemalans, and Maya believed in the past -- unlike the people of the Mediterranean, who were always suspicious of the tales and retellings of their forebears. I think also that texts were only added to the graphic books after about 600 BC.

Considered in detail, the thought system of the Maya exhibits the same rationality in navigating this intricately detailed imagined spiritual space. It does not involve "facts" as we understand them, that is, events placed in a continuity of time and a contiguity with other observations, but is instead totally based on firmly believed interactions between the realms of the real and the spiritual. Yet it represents a way of thinking which is far removed from mere acceptance of the world. The Mesoamerican "philosophy" also dates (I suspect) to after 600 BC. It was widespread and uniform when the Spanish arrived. The histories written after the time of the Spanish of the ball-playing twins, written 2200 years after the events (and the surviving celebrations which still exist today), point to the stability of the underlying philosophy.

Some of the new science went awry, of course. The Babylonians (Chaldeans) had made astronomical observations dating back perhaps to 2300 BC. But only in the seventh century BC is this seriously developed into a "science" of astrology. This effort was a giant leap into an arena of correlation between observed celestial and earthly events which the same people had been incapable of even imagining during the previous 2000 years. What made this particular "science" valid to them was the assumption that the planets, identified with the Gods of old, still regulated the lives of men and controlled events on Earth, just as the Gods had always done.

Holding On to the Past

The ultimate effort everywhere was to explain mankind's existence and formulate a code of proper behavior. By 500 to 400 BC the Greeks had reached an intellectual level which is

completely modern to us. And yet, at times the past peeks through. The same philosophers who could verbally extract the roots of quadratic equations, held fast to omens and espoused the prophesies of oracles with certitude.

The prophetess at Delphi, in effect, ruled the whole of the Greek political world for 1000 years with her instantaneous answers to questions about colonization, leaders, laws, enemies, and personal fortunes. Thucydides, writing about the Peloponnesian Wars (430 -- 404 BC), in detailing all the human failings in the course of events, never fails to append his histories with the pronouncements of Delphi to show how the prophesies had been accomplished. The *New Testament* uses prophesies in the same manner, as authentication. Plato, in his otherwise completely cynical writings, holds the Delphic Oracle in high esteem.

Omens, prophecy, and foretelling of the future remained very serious practices lasting well into the current era. (The *Sibylline Oracle Books* were still in circulation in the 16th century AD.) The concept of "free will" was developed in Greece in classical times (400 BC), but not widely accepted for another 2000 years. The Greek tragedies hold that "fate" runs the lives of men, resulting in plotlines often completely inexplicable to us as modern readers. The idea of "chance happening" does not take hold in Europe until well after the Middle Ages. [\[note 17\]](#)

The past maintained a particular hold on the people of South America and Mesoamerica. For Mesoamerica, the observation of Venus remained a primary theological obsession, especially for the Maya, who record yearly corrections to a base calculation of the location of Venus which comes closer in estimating its movements than the Europeans would be able to do for 200 years after they "discover" the Maya.

For the Aztec, the pacification of the Gods remains at the center of life. The Aztecs, the people of Mars, had successfully kept cosmic misfortune at bay, for hundreds of years, at the cost of many thousands of lives, when the Spanish arrived in AD 1492. Even in the last battle with Cortez's soldiers over possession of the city of Tenochtitlan, the Aztec warriors take time out from battle to drag captured Spanish soldiers to the top platform of the temple of Huitzilopochtli to rip out their hearts. The sacrifices were necessary measures as long as the return of the unpredictable Gods remained a possibility.

The Presence of God

It seems almost unbelievable that the altered night skies, and especially the rotation of the dome of the stars, would have the effect that it did in generating a half dozen new religions, initiating an historical awareness, and be the genesis of the study of physics. It is even more astounding to see these changes happening worldwide and at almost the same time -- in Babylonia, Greece, India, China, and Mesoamerica. The simultaneity of the interests in these topics is amazing, especially considering the lack of cultural contacts. This has been remarked upon by others.

If you look for the history of any of the Greek cities, or the nations of the Middle East, or China, you will see that in most instances history cannot be traced back before 600 or 700 BC. Everything disappears into legends. It is as if the world suddenly woke up, and abstract thought was first allowed after 600 BC.

I should point out, however, that the changes in outlook did not come easily. Plutarch, writing in the first century AD, tells of Anaxagoras, after about 500 BC:

"Anaxagoras was the first to put in writing, most clearly and most courageously of all men, the explanation of the moon's illumination and darkness. His account was not common property, but was a secret, current among only a few. For in those days they refused to tolerate the physicists and stargazers, as they were called, who presumed to fritter away the deity into unreasoning causes, blind forces, and necessary properties."

"Anaxagoras was accused of impiety and sentenced [to death] for holding that the sun is a red-hot stone and the moon is of earthly nature. This was in disagreement with the view that these luminaries were deities."

By 650 BC we have a society of vagabonds and inland survivors in Greece. The coastal people had been decimated with the repeated strikes of Mars. The up-land goatherd survivors had no earthly history of more than one or two generations, no genealogy except that which linked to mythical beings, and no homes. For the mainland Greeks and those of Asia Minor, the devastations of the 8th and 7th centuries BC had made a complete break with the expectations of the past and with the conservative attitudes of the past. The time and the place were ripe for something new (de Grazia).

The fact is that far-flung regions of the world all simultaneously came to the same conclusions about the universe and the world. This suggests the possibility of something global being the cause of the new sciences, philosophies, and inquiries.

Two recent events are possibilities. The earlier instance of the "Tower of Babel" event was in 2150 BC. This was the flaming of Jupiter. A second "Tower of Babel" event is dated to 686 BC (astronomical), and seems to be universally attributed to Mercury. These later "Tower of Babel" stories are worldwide, which also suggests that the event was recent, and not 1500 years earlier. But in both cases the "event" preceded a change in the attitude and awareness of humans. The fire of Jupiter in 2150 BC precedes a jump in awareness of around 2000 BC. This date can be understood as the time when the first historical interest seems to have developed.

But in terms of a timetable for the development of philosophy, science, and religion, the date of circa 2000 BC is far too early. The electrical contact by Mercury in 686 BC happened directly before the blazing of Venus and Mercury in 685 BC. Mercury, I should point out again, is the only inner planet (besides Earth) with a magnetic field, although minor. It might be coincidence but this also preceded a jump in awareness for humans.

The other thing which stands out, besides the "Tower of Babel" event, is a change in the size of the plasmasphere of the Earth. This can be concluded from the precession of the equinoxes. Before 747 BC there was no precession of the equinoxes. This is certainly to be recognized from the multitude of data which points to the fact that the same constellations were held to be the centerpoints of the spring and fall equinox -- Taurus and Scorpio -- for the time before 685 BC, which can be extended to 747 BC. Precession was only noted after 400 BC in Asia Minor and after AD 300 in China when it became obvious. To notice the precession of the equinox requires the accumulation of data for more than a hundred years, since the rate is about one degree in a hundred years.

The lack of precession before 747 BC means that the Moon did not exit and reenter the Earth's plasmasphere in traveling "around" the Earth. Today the plasmasphere of the Earth has a dimension of 10 to 20 Earth diameters on the Sun side, thus 80,000 to 160,000 miles. The Moon today remains within this for only part of its orbit. The Moon moves outside the plasmasphere when it travels to the Sun-side of Earth, because the radius of the Moon's orbit is 250,000 miles, and the plasmasphere of the Earth is currently at best only 160,000 miles. That means that before 747 BC the plasmasphere of the Earth must have had a dimension of some 30 Earth diameters on the Sun-side -- 240,000 miles -- large enough to keep the Moon wholly within the Earth's plasmasphere.

It is not the Moon, however, or the precession of the equinoxes, that changed our behavior. These changes are much too slow to account for the sudden changed attitudes and interests after about 600 BC. What I am suggesting here is that the Earth would have been at a much different electric potential with respect to the surrounding space of the Sun. That probably happened after 685 BC. If the Earth's plasmasphere shrunk after 685 BC, then it was because the electric field of the Sun had dropped in intensity. And this in turn might have been the consequence of Mercury moving to an orbit close to the Sun.

... lowered potential

We cannot neglect that the Sun changed its output for 40 days in 685 BC, or the fact that Jupiter released a thunderbolt. But these were temporary events. We could assume that it represented an adjustment in the flow of plasma from the Sun (the solar wind) after the change in orbit of Mercury in 686 BC. In 686 BC Mercury for the first time assumed an orbit entirely within the orbit of Venus. This must have caused a radical change in the conductive path for the solar wind or at least a change in the electric field at the exterior to the Sun. Certainly the Earth also made an adjustment in its electric parameters if Mercury, Venus, and Jupiter did so.

There might be effects on the physiology of humans resulting from a voltage difference from head to toe, but I doubt it, for this is but a small fraction of the voltage difference from ground to the stratosphere or the ionosphere, or certainly to the location of the double layer of the Earth's plasmasphere.

The only thing I can suggest is that the era before 685 BC would have experienced much more active electrical interactions between the upper atmosphere (or ionosphere) and ground level -- in terms of thunderbolts, Saint Elmo's Fire, but especially in terms of things like ball lightning. I am suggesting this last because the psychological effects are still experienced today, even though ball lightning occurs only infrequently.

I will start with a note on ball lightning as a minor version of the larger crop circles. There are similarities in that both are manifestations of moving plasma. Ball lightning is an example of a spherical plasmoid, which is self-sustaining, at least for a lifespan measured in seconds or minutes. And then they disappear. But this is actually most likely a mode change for ball lightning. The disappearance would make the original grapefruit-size ball plasmoid in glow mode into an invisible sphere in dark mode perhaps ten or twenty feet (3 to 7 meters) in diameter or larger. This could easily engulf a nearby human, resulting in a feeling of "presence" of another being (as what also happens when we sense another human or animal nearby).

Various people have expressed everything from nausea to terror in the presence of extinguished (dark mode) ball lightning but especially in crop circles. My one-time experience after extinction of nearby ball lightning was of terror, being certain that there was "somebody else" near me -- in the middle of the night, no less. As others have said, once you meet up with ball lightning, you never forget. Typically perhaps, I think people will localize such an experience (I did), so that it becomes associated with a place and a condition. Specific to crop circles, BLT Research (Internet) reports:

"A wide range of anecdotal reports exists of the effects on people. These reports have not been scientifically evaluated, but it seems clear that many people experience unusual physical effects in some crop formations -- and most often when the crop circles are relatively new. These effects range from the unpleasant (splitting' headaches, dizziness, disorientation, heart palpitations, a sense of 'dread') to the euphoric (a strong sense of 'peace,' a feeling of joy, a sense of 'oneness,' and a feeling of love).... Many people have also experienced the sensation of a presence of some sort -- other than their own, and invisible -- while inside crop circles."

"It is easy, perhaps, to dismiss such reports as being due to some sort of hysteria or over-excitement, and there seems to be no evidence of long-term effect to either people or animals. However, the fact is that a large number of field personnel who have spent considerable time in the formations, as well as some of the more casual visitors, have experienced one or several of these effects in crop circles all over the world. The fact that most of these experiences are reported in newly formed crop circles suggests there may be a remnant energy still present at some of these sites, to which at least some people are sensitive. It is most interesting that these effects do not seem to be present at all crop circles, and that, even when some people are affected in a particular event, other visitors will be unaware of anything unusual at all." -- BLT Research,
<http://www.bltresearch.com> [\[note 18\]](#)

Because of the life-long recurring dread or feeling of potential contact for anyone who experienced this condition, I think it would take a generation or two of people who never experienced this, before we would see the intellectual effort to summarily dismiss the tales told by their parents and grandparents. Agnosticism fills the void of missing evidence -- the missing experiences your grandparents told you about. And agnosticism then searches elsewhere for meaning. That certainly was the case for the Greeks, and seems to have been the case in China and India and Israel. Nothing like it in Egypt, of course.

What was missing then, after 685 BC, was the potent and palpable presence of God. That was the difference, I think, between the period before 685 BC and the period afterward.

I started this text to suggest that the effect of lowering the Earth's negative charge (or specifically, the Earth's potential) after 685 BC, suddenly made us humans much smarter -- philosophically, scientifically, and probably religiously also. We suddenly see a vast outpouring of literature, philosophical speculation, historical inquiry, all starting within two generations after 685 BC. The connection between 685 BC and the start of philosophy and physics is startling. There is a gap of two generations -- the time it would take for grand children to no longer believe in the old tales. But it must have taken more than just a generational difference, for religious traditions die hard. This change was sudden and radical. What I will suggest, therefore, is that the changes that were experienced were entirely due to the cessation of the effects of ball lightning and allied forms of plasma transfers between the Earth and the upper atmosphere and I will suggest "crop circles" instead of ball lightning as the prime agent.

... crop circles and ball lightning

The following is an example of very powerful ball lightning:

"In May or June of 1988 or 1989 around 2 P.M. CEST, Mr. Alois Fuehrer, a farmer of 38 years from Jungschlag, a small village South of Ottenschlag, Northern Lower Austria, 850 meters above sea level, returned early from fieldwork because a heavy thunderstorm moved in from the north-west. Fuehrer stood in the open on a wooden plank at the rear of the diesel tractor driven by his father."

"The vehicle had passed the last Ottenschlag houses southbound, when he noticed a falling object. It was round, 20 centimeters across, and 'seemed to come down like a toy balloon', vertical, soundless, without rotation. It was brilliant white, a steady light, and had 'something like a smoke trail'. Only 20 to 30 meters to the right of the tractor and of the road, after 4 to 6 seconds, the object hit the surface of a green summer barley field, flashed up and 'exploded with a loud, very high pitched bang.' Mr. Fuehrer said 'this was no thunder,' and noticed no heat or pressure wave. However, what he felt caused panic -- a tingling, and his hairs stood on end on his head, neck, even on his hands. He

urged his father: 'Get out of here, the next one will kill us!', who also felt the electrostatic effect in the driver's cab. The diesel tractor continued to function normally."

"Arriving home, the Fuehrers still wondered what had happened and they went back to have a look on the same evening. They found a circular patch about 6 meters [18 feet] across in the impact area where green barley plants had been reduced to ashes and smoke, 'as with a cutting torch.' The burn effect was strongest in the center. The soil had not been moved."

-- From William Corliss, <http://www.science-frontiers.com>.

Although there is certainly a close similarity between ball lightning and crop circles, I don't think crop circles are simply the result of ball lightning (farmer Fuehrer notwithstanding). In glow mode or arc mode, these forms (the ball lightning) are tremendously variable in their amazing displays and lifetimes, but the power level is simply too low to account for the large-scale effects produced at crop circles, like leveling a 30-foot diameter circle of full grown wheat crop in under a minute. Ball lightning is estimated to require only 25 watts of power to sustain a 10-inch diameter ball in glow mode for periods of 2 to 10 seconds. That is almost nothing. Even a ball which shines at a brilliant 5000 Kelvin (which has been observed) and melts a circular hole through a window, is not exhibiting much beyond what a quartz utility-light produces -- perhaps 500 watts.

There are simply no available data on the energy requirements of a grain crop circle. It would at any rate be difficult to evaluate the forces required to heat and bend the grain in a 30 feet (10 meter) diameter circle. There is, however, one report on a temporary crop circle formation on water, at the Loosdrechtse Plassen, a series of lakes in the province of Utrecht, in Holland, in June of 2002, by Martin van Wieringen, a Ptah Foundation (World Mystery Research Center) observer:

"After a short trip with my boat on the Loosdrechtse Plassen at 01-06-2002 around 3:30 pm, I saw a sort of a mist on the water surface which appeared suddenly. The result was a fast rotating cylinder of water with a diameter of approximately 20 meters on the water surface. This cylinder of water was "sucked up" from the surface with a height of approximately 2 or 3 meters. The pattern of the cylinder looks similar as a vortex pattern."

"First I thought it was a tornado, but that wasn't what causes this cylinder of water. This because the cylinder was flat at the top. The cause of this cylinder of water sprayed the water on top of the cylinder. The result looks the same as a combination of a tornado and the properties which are characterized of how crop circles are formed. After approximately 15 seconds the cylinder collapsed, but after a short break another rotating force was following a long "path" of approximately 50 meters. After this path disappeared, a new cylinder of water rises from the surface. This cylinder had a

diameter of approximately 8 meters."

-- *Dutch Crop Circle Archive*, <http://www.dcca.nl>

At 1000 kg per cubic meter, 630,000 to 940,000 kg of water were raised two to three meters above the water level, and forced to travel in a circle for 15 seconds. That is certainly a lot more energy than what is associated with ball lightning.

I have experienced waterspouts on Lake Michigan (as a pair), but they rose into the sky as funnels; they were not flat topped.

John Abrahamson, A. V. Bychkov and V. L. Bychkov have presented a collection of ball lightning encounters (still held to be "fantasies" and "delusions" by scientists), in "Recently reported sightings of ball lightning: observations collected by correspondence and Russian and Ukrainian sightings" (*Philosophical Transactions of the Royal Society*, 2002).

The contents of this paper reiterate what is already known about ball lightning, with the exception of the violently exploding dropped "ball of light" reported by farmer Fuehrer.

Abrahamson, with J. Dinniss, also constructed a model for ball lightning, detailed in "Ball lightning caused by oxidation of nanoparticle networks from normal lightning strikes on soil" (*Nature*, 2000), which suggest that ball lightning represents the slow oxidation of nanoparticles of silicon from soil vaporization due to high-temperature lightning strikes. Amazingly, almost all the properties of ball lightning can be ascribed to this chemical process.

Similarly, David Turner, in "The fragmented science of ball lightning" (*Philosophical Transactions of the Royal Society*, 2002), attributes ball lightning to a process of hydration of the outer shell of atoms or ions.

Lastly, and as yet another example, J.B.A. Mitchell, et alii, in "Evidence for Nanoparticles in Microwave-Generated Fireballs by Synchrotron X-Ray Scattering" (*International Conference on Phenomena in Ionized Gases*, 2007), passed x-rays through small ball lightning created and sustained in a microwave oven. The scattering pattern suggests very small "nanoparticles" internally, which would seem to confirm the work by Abrahamson and Dinniss, mentioned above.

[Image: Type structures for ball lightning; after Lars Wåhlin.]

There are many other research papers published. Much of it comes close to the effects experienced with ball lighting, although extensive efforts are made to explain all the aspects of ball lightning chemically. (It is additionally not at all certain if "nanoparticles" exist.) An explanation for the exterior glow is generally missing, something which electrical engineers would at once attribute to a space charge (thermonic emission), often represented as a "boiling off" of electrons. The most obvious and easily recognized space charge effect is the glow of electrons surrounding the cathode of a neon lamp.

Ball plasma is also suspected of setting up a resonant space, within which the electric and magnetic fields will assume a mosaic of patterns. Since ball plasma in arc mode is generally only 12 inches in diameter (1/3 meter), they would be operating at a frequency of around 1 gigahertz (300,000,000 / 0.3). That is what is normally considered the "shortwave" or "microwave" range.

Lars Wahlin (Wåhlin), in *Atmospheric Electrostatics* (1989), a book which deals with the generation of terrestrial lightning, identifies two forms of a toroidal current or a toroidal magnetic field, each capable of producing an accompanying magnetic field or current flow. Wahlin suggests that the form with the internal magnetic field as being due to the constriction of an encircling magnetic field which pinches and cuts off a flow of current in a lightning strike. This effect has actually been observed by others. A collapsing magnetic field will induce a corresponding electric field.

The point of this is not to suggest that crop circles are degenerate ball lightning forms, but to support the fact that any moving plasma stream also produces a corresponding magnetic field. The vector product of the magnetic field and the current flow will produce a force attempting to change the direction of the current carriers -- in effect at right angles to each other. This is known as the "right hand rule" of Force, Magnetic Field, and Current (where each of these is expressed as a vector) and is the basis for the design of electric motors and generators.

... fake crop circles

Most crop circles are hopeless fakes. Even the True Believers (with apologies to Eric Hoffer) say so, and I'll buy that opinion, even if their analysis is presented in a jargon of intersecting magnetic and geodetic lines, the relationship to ancient monuments, and "remnant energies" - with much of the geometry of intersecting lines and the feelings deduced through dowsing.

I would dismiss "dowsing" as a source of information about crop circles (or anything), but it is a fact that the same investigators report detecting the feeling of dread and nausea after entering "genuine" crop circles. If this is the "remnant energy" of a crop circle event, what exactly is felt? The word "energy" in common usage represents "potential forces, inherent powers" -- things like that, but all related to human interactions. The word "energy" in physics means something entirely different, it is "work" -- in the most basic form it is a force moving a mass through some distance.

Anyone who has taken a course in physics or mechanics would be loath to give recognition to psychological or spiritual "energies." With this in mind, the question then is, What could be felt physically after a crop circle event? The feelings of energy, dread, and nausea seem to fade with time. Humans do not react to changes in the magnetic field, or to nuclear contamination (not quickly). We do react to changes in temperature and barometric pressure, the last of which is often recognized as the dread of an impending storm. But local barometric pressure is difficult to relate to the movement of plasma, because the inflow of the surrounding air would equalize the pressure within seconds.

But what can readily be felt, almost always, is static electricity. It remains for some time and only slowly leaks away. This is most likely the "remnant energy" as well as the "dread" felt by people in recently made and genuine crop circles.

Genuine crop circles, predictably (and as readily pointed out by any number of crop circle enthusiasts), are simple designs without symbolic significance, can be placed in fields equipped with alarms, take under 2 minutes to form, mostly come into existence at the edge of night and day (this is not entirely certain), bend grain at the nodes by (apparently) softening the nodes and then bending the stalks at 90 degrees, blow holes in nodes (suspected as due to overheating of the sap with microwaves), leave scorch marks at the base of some stalks, alter the DNA of seeds and thus their genetic future, interweave grain stalks in contrary directions, pull selected exterior stalks into the circular design, deposit ferrous iron in the soil and on plants, leave behind distinct radioactive isotopes, change the local magnetic deflection by about 4 degrees (supposedly), and dry out the soil locally.

... infrequent crop circles

Real crop circles are actually very infrequent, and the number drops every year with a drop in the number of sunspots (like the auroras do also). Even the True Believers in the UK have noted that of a hundred or more crop circles appearing in a recent summer (2010), there was not likely to be more than 1 "real" one. It has also been noted that 98 percent of crop circles

appear after the weekends, and after Bank Holidays. That says something!

This candid attitude of some of the UK researchers is refreshing (my source is Freddy Silva and his site <http://www.cropcirclesecrets.org>). But the problem I continue to have with the True Believers is that they are still convinced we are getting messages from aliens, and even see these as psychically induced in the fake crop circles. In other words, it is assumed that it takes an intelligence to produce the circles, although all we seem to be getting (in the fake circles) is a roundup of geometric forms from high-school geometry and physics text. It is the sort of thing any juvenile could do. Even the supposedly vastly clever binary encoded messages used the standard ASCII character set.

The whole idea of assuming an alien intelligence is another case of "intelligent design" as a solution to the inability to imagine long time-periods, minute small changes, and the possibility of intricate biological mechanisms, or, in this case, imagine what a self-sustained plasmoid could do.

The other thing I find objectionable is that the True Believers can only extend their imagination to contemporary wants and desires. A thousand years ago people would have suggested that aliens should bring us eternal life and gold. Today it is "advanced technology" and "new mathematical theories." I cannot believe this simplistic attitude. If I wanted anything from the aliens, it would be a deliverance from our ferociously murderous antipathy toward each other. Second would be deliverance from lying politicians and, third, greedy people.

... genuine crop circles

What I am suggesting here is that crop circles are real, although very rare (especially today), that these had probably been experienced much more frequently in remote antiquity, and that they are the result of a spherical geometry of dark mode plasmoids exiting the Earth's surface. This claim can be made despite the fact that there are many fake crop circles (estimates of 80 percent fakes by Colin Andrews in 2000, and estimated at 99 to 100 percent by Freddy Silvas in 2010).

In remote antiquity the experience of crop circles would have been much more frequent, and would have been convincing evidence of being in the presence of a God, localized to a sacred site. Entering the room where at night I once experienced ball lightning still sends shivers down my spine. Imagine being out in a field in Neolithic England and seeing grasses suddenly bending to lay down in a circular geometric formation, accompanied by the certainty of a "presence." The humans of the early Neolithic in England must have recognized the condition. Crop circles today appear with the greatest frequency where circular monuments were built in the Neolithic. God was visiting. [\[note 19\]](#)

... plasma defined

I think, then, that crop-circles are caused by rising elongated plasma streams in dark mode (imagine it to look overall like a giant rotating turnip or carrot), and thus of large sizes, 20, 30, or 40 feet (7 to 13 meters) in diameter. Other people have also reached the same or similar conclusions over the last decades, although some of it was given over to weather phenomena. But plasma streams and even ball lightning have only recently come forward for consideration. [\[note 20\]](#)

Plasma is a diffuse stream of electrons or ions (or both). If it travels down from the ionosphere or upper atmosphere it will tend to form into tightly compressed streams. In various quantities of plasma flow, these are dust devils, waterspouts, tornadoes, and, in much larger form these are hurricanes. Lightning is plasma in arc mode (from intermediate cloud layers). "Plasma" is thus a term loosely meaning a continuous flow of electricity.

[Image: Dust devils on Mars; after NASA.]

For dust devils, waterspouts, and tornadoes, electrons or negative ions (O_2 and NO_2 anions) are moving to Earth; the flow of current is thus upward. This defines a counterclockwise circular magnetic field, as seen from above, surrounding the stream of electricity. Any ionized material near the base will try to follow the circular magnetic field lines and rotate around the center of the plasma stream. This would include dust and dirt from the surface which would be positively ionized by induction. Tornadoes are the most pesky manifestation.

Dust devils are seen on Mars, rising 300 hundred feet (100 meters) up from the surface, although there is almost no atmosphere on Mars. The tornado-like forms consist entirely of ionized dust. Electric arcing can be seen at the base where the devils touch the surface of Mars and where these cyclones concentrate current flow to arc mode. They leave behind blackened trails.

The base of a tornado is tubular, and rasps the Earth like a router. The magnetic field at the center is downward directed, and up directed at the outer edges. The loosened dirt, trees, cars, houses, and other debris are levitated electrically (aided by the upward directed magnetic field) at the outside of the funnel -- not in the interior.

As opposed to tornado forms, I would suggest that crop circle plasmoids rise out of the ground. If the crop circle plasmoid is of a limited size, then the flow of electric current will create a solenoidal magnetic field within the core of the plasmoid, and directed oppositely on the exterior of the more or less tubular plasma formation.

The travel of an electric current, which will also exhibit itself in the stems of grain crops (since the stems are conductors), will produce a force at right angles to the direction of current flow and at right angles to a magnetic field, attempting to move the conducting stems into a path at right angles to the overall upward movement of the streaming plasma. The individual blades of grass would experience this force. The flow of electricity in the grass is upward at the outer circumference and otherwise inward directed. That would result in snapping the grass blades at right angles at the nodes (a weak point), and tangentially to the radius of the crop circle. And this is the effect that is seen.

Let me add perhaps another few qualifications. First, as suggested above, the plasma streams upward, based mostly on the Loosdrechtse Plassen experience. This could reasonably be expected also from the fact that the Earth maintains a charge balance, so that, for example, charge transferred to the surface via thunderstorms or tornadoes will be offset, sooner or later, by plasma streaming away from the Earth.

Second, there is no reason to suggest that the streaming plasma could not revert to glow mode or even arc mode on moving up past the surface of the Earth. This is plasma; almost any form could be taken. There are a number of instances of observers having seen brief beams of light emanating upward from attested genuine crop circles.

The crop circles are all about that, apparently, except that the True Believer observers think that something lowers to the ground from higher up -- thus you get claims of flying saucers and extraterrestrials. I think it is more likely that these phenomena move up from below ground, since they keep occurring in nearly the same locations. The direction of travel, together with occasional observations of lighted spheroid shapes (even photographed at some crop circle locations), would suddenly account for various "UFO phenomena." UFOs almost always rise up, they are not seen to lower to Earth. [\[note 21\]](#)

Special thanks to R Houston for pointing out the plasma sources.

Special thanks to R Boerman for a discourse on crop circles.

Endnotes

Note 1 --

Leroy Ellenberger, "An Antidote to Velikovskian Delusions" in *Skeptic* (1995) or at <http://abob.libs.uga.edu/bobk/velstcol.html>. But the point of a valid criticism is entirely missed. All the Saturnian writers almost to a man have assumed without hesitation that the source data for the essay by Jastrow is applicable to the period before 3147 BC -- the "Era of the Gods" -- rather than entertaining the possibility of a very late period.

It is just insane to suggest that any people would keep such idiotically detailed records alive for 3000 years. As a matter of fact, almost all of the associated records which do not deal with planets are clearly contemporaneous economic records from the 8th and 7th century BC: the cloud cover in the morning, the prices of grain, dates, and lumber. And as soon as the Assyrians lose their control over the fortune-tellers and astrologers of Babylon (in 612 BC), the records cease. Almost all the Babylonian records date to after 650 BC.

[\[return to text\]](#)

Note 2 --

Revelations is based entirely on contemporaneous astrological concepts of the first century AD. The letters to the seven churches, which open the text, are addressed to the seven planetary Gods. The sign of the beast, 666, represents the number of years needed for a change of the equinox of one decan -- ten degrees -- along the ecliptic. The number 666 is one of the measures for the precession of the equinox current after the second century AD (66.6 years for one degree; today this is 72 years). The "beast" refers to the bestiary of the zodiac.

[\[return to text\]](#)

Note 3 --

The King James Bible quotation is awkwardly worded, "I will bring again the shadow of the degrees, which is gone down in the sun-dial of Uzziah, ten degrees backward." Ronald Knox has, "see how low the shadow has fallen, with sun-down, where the dial of Achaz [Uzziah] marks the hours! I will make it go ten hours back."

We are, at any rate, talking about a shadow which was longer than expected (it was a winter-time shadow). At a latitude of 31.68 degrees north, the Sun at the equinox assumes an angle

of 58.34 degrees with the horizon (58.38 before 685 BC). After 685 BC, in 684 BC, the Sun culminates at 52.34 degrees on March 6th -- on the old day of the equinox.

The reciprocal of the tangent, $\cos(\)/\sin(\)$, measures the shadow on the ground as a fraction of a gnomon of unit height. Thus the shadow on March 6 (on the equivalent day of March 21), before 685 BC, was:

$$\cos(58.38) / \sin(58.38) = 0.615.$$

On March 6, 684 BC, it was:

$$\cos(52.34) / \sin(52.34) = 0.771.$$

The fractional difference in the shadow is:

$$(0.771 - 0.615) / 0.615 = 0.25,$$

... representing a lengthening of the shadow by 1/4th of the original length.

Note 4 --

Charles Raspil "Planetary observations of the T'ang" (1994 *International Velikovsky Symposium*). The base information is from Edward Schafer, *Pacing the Void, T'ang Approaches to the Stars* (1977). Raspil supplements it with information from European, Byzantine, and Islamic sources. Raspil writes:

"Probably because of his shock at finding so many incredible astronomical observations (for e.g., fixed stars that blink on and off, or disappear for awhile, or appear with horns or other appendages; or planets that give off ribbon or flag-like emanations), Schafer attributes to T'ang astronomers talents that suggest that their greater competence is as whimsical poets."

Raspil could not deduce a consistent pattern, except to suggest that many anomalies happened during "conjunctions." Kepler is quoted as an example of the thinking of medieval astronomers (astrologers) on conjunctions:

"experience shows that all sorts of meteors were seen when the planets were configured in aspects, whereas the air was undisturbed otherwise."

"Aspects" are the angles made by celestial objects to each other, measured across the 360 degree circle representing the dome of the stars. On March 18, AD 904, Venus was indeed very close to the Pleiades.

[\[return to text\]](#)

Note 5 --

I should note that Velikovsky may have "Venus not added" wrong. In an address by Abraham Sachs at Brown University on March 15, 1965, Sachs noted:

"In 'Worlds in Collision', p. 161, Dr. Velikovsky says that Babylonian astronomy at one time had a four-planet system, with Venus missing. For this, he refers to a book written in 1915. Not being a cuneiformist, Dr. Velikovsky cannot inspect the original text referred to in his 1915 source. I have read the text and I can report that it is quite true that Venus is missing in the text-- but so are the other four planets. Dr. Velikovsky's 1915 source mistranslated the names of four fixed stars as planets."

A transcript is at <http://abob.libs.uga.edu/bobk/vsachs.html>.

Marinus van der Sluijs in "gods-and-planets.htm" at mythopedia.info [since removed] provides an extensive critique of the ready willingness with which the Saturnians (Talbot, Cardona, and Cochrane) assign the Gods of the Polar Configuration to various planets (as I have done as readily). He writes, about the Babylonian astronomy after 600 BC:

"The fact stands that the Babylonians often employed the same divine names for various planets. [And, it should be noted, also mixed them with the names of stars and constellations.] Why they did so is far from clear to us. It seems unlikely that the Babylonians of the first millennium BCE could not properly distinguish between the various planets. David Brown [see the text] argues that a name applied to more than one planet in the period he studies has nothing to do with confusion or unclarity on behalf of the Babylonians, but is indicative of a system whose rationale escapes us today."

"The 'logical problem' introduced with the realization that myth communicates with us through symbols, simply forbids us to take the mythical or folkloristic statement that the gods were planets literally. If we accept that a god was Mars or Saturn because the myth says so, we ignore the principle that myth speaks through symbols. What we ought to suggest, acknowledging both the planetary association and the symbolical nature of myth, is that a certain visual prototype was symbolised by the myth-makers as the planet, because of certain similarities the planet had in common with the remembered prototype."

Myths are not "made." They are recollected history, and have no symbolic content, despite the three assertions by vd Sluijs in one paragraph. If Van der Sluijs conceives of myths and legends as "symbolism and displacement metaphors," I think he is making an enormous mistake for a self-proclaimed mythologist. I have been at pains to explain that the ancients were incapable of abstract metaphorical reasoning and symbolic notions in earlier times, and certainly did not "think" in the manner understood by us. Van der Sluijs's insistence on "symbol and metaphor" introduces an unwarranted and unneeded contemporary point of view

when applied to concepts which have their sources in remote antiquity, although by the 8th and 7th century BC, the use of metaphors and symbolic reasoning was certainly in use.

By his own admission, van der Sluijs argues exclusively from the mythological point of view, not, as he states, from an interdisciplinary perspective (which would include the hard sciences), although he will readily admit that the legends and myths have their genesis in the visual effects of the polar display. Additionally he quotes extensively from older sources, none of which have considered earlier celestial catastrophes or the confused sky up to the seventh century BC as influencing the identification and naming of the planets.

In my point of view, the primary Gods to the ancients were real persons who could be seen in the sky -- as globes which today we call planets. Only after 1200 BC or so do they start to acquire spiritual qualities. To the Chaldean (Babylonian) prognosticators of the 7th century BC, the Gods had indeed become physical entities, which moved across the sky like so many chess pieces to determine the fate of nations and individuals, and had to be treated yet with respect, for the priests were in the employ of the pre-conscious Assyrians to whom the Gods were still very real personages. Contemporaneous with the Assyrians and Chaldeans, Homer treated the Gods in complete mockery.

Lastly, it has been noted that the names of the Egyptian Isis, Osiris, Horus, and Seth, the Greek Athena, Kronos, Aries, and Zeus, the Sumerian Inanna and An, the Canaan Ishtar, and Babylonian Marduk (and more) do rotate somewhat haphazardly among the planets Venus, Saturn, Jupiter, Mars, and Mercury. The correct identities are not always certain. The best test is to use the insight of the Greeks during classic times, that is, if two Gods have similar histories and characteristics, they *are the same* even though they might be known by different names in different lands.

Note 6 --

Mithra is also one of the Hindu pantheon, representing the shining Sun disk of daytime, and was also known among the Hittites of Anatolia in circa 1500 BC, as well as among the Zoroastrians. His popularization is likely due to the influence of Mazdaism at the time of the Persian Empire.

Note 7 --

See David Ulansey *The Origins of the Mithraic Mysteries* (1989). Most of what we know about Mithraism is from the writings of the Church Fathers -- Jerome, Tertulian, and others, plus a number of Greek and Roman authors. Ulansey comes to the same conclusion as I do, that is, that Mithraism is in response to a change in the equinox. Ulansey bases his theory on the suggestion that a knowledge of the precession of the equinox came to light in the third or fourth century BC, despite the fact that the iconographic references of Mithraism are to

Taurus and Scorpio as the constellations of the equinoxes. Using today's estimate for the precession of the equinox, and assuming that the precession of the equinox had always been the case for Earth, this would place this configuration in about 2000 BC. This is unlikely as a remembered condition, and cannot be related to any significant event. There are just too many intervening events and religious rethinkings to make sense of this.

Ulansey equates the stance and gesture of Mithra in sculptures to the depiction of Perseus after decapitating Medusa (the Gorgon), that is, looking away. He also draws parallels between the Gorgon and the frequent depiction of a lion-headed God entwined by a snake and standing on a globe representing the Earth, or, more likely, representing the globe of the stars as seen from a remote exterior. This apparently became a standard depiction in the Middle East and Greece. Globes of the stars at this time start to show both the equatorial and the ecliptic as encircling bands.

I could add to the confusion of associated imagery by noting that the Gorgon is Venus blazing in 685 BC with plasma streamers as hair, although Perseus is nowhere nearby (Perseus is above Taurus). Additionally, the image of the Gorgon is much older than 685 BC. Medusa is one of the three sisters of the south of remote antiquity, dating to after 10,900 BC. She is the main ball plasmoid which could not be looked at -- but only because it was far too bright to endure. Peratt has suggested the brightness also, in noting that many petroglyphs were carved only where the artists would be shaded from the brightness of the ball plasmoids.

Ulansey's lion-headed God is the Sun in the constellation Leo on July 25th of 685 BC, when the plasmoid from Jupiter landed after midnight and the eastern sky blazed for nine hours. The entwining snake is (likely) the plasma plumes appearing at the north and south magnetic poles of Earth under the conditions of a radical change in the field of the Sun.

What confirmed for me the common core of this diverse and unfamiliar imagery was the depiction of the lion-headed God as item 312 in Maarten Vermaseren's *Corpus Inscriptionum et monumentorum religionis mithriacae* (1956), where the statue wears a plasmoid bolt on its chest, rather than the usual Gorgon head. This is also illustrated on page 33 of Ulansey's book.

Note 8 --

Although I guessed at this, as I found out later, David Ulansey also agreed that the boys with the torches represent the vernal and autumnal equinox, and Ulansey also admits that the symbolism is at times reversed. I did not check to see if Ulansey considered the visual crossing of the ecliptic and the equatorial or the factual crossing.

The crossing of the equatorial and the ecliptic is also notable in Mesoamerican iconography. The same symbol is used, the Saint Andrew's cross, where one of the diagonal bars crosses

the other, a different configuration for the spring and fall equinox. For the vernal equinox the bar starting at the upper left crosses in front of the other. The autumnal equinox reverses this. The visual representation in Mesoamerica is based on the shadow of the Earth falling on the last ring of the Absu, which lasted well into the current era.

Note 9 --

The event of 685 BC had happened 80 years before Lao-tse was born. Reading "Tao" as the road, meaning the zodiac, and "Thien" as heaven, meaning the dome of the stars, the text, although with obvious strong philosophical rather than scientific overtones, becomes immensely elucidated. See especially the introduction of James Legge in the *Sacred Books of the East*, Volume 39 (1891) and the comments on translations by Kelley L. Ross at [\[www.friesian.com/taote.htm\]](http://www.friesian.com/taote.htm).

A typical interpretation of Taoism was made by Sze-mâ Khien, writing, in the first century BC, "Lâo-dze [Lao-tse] cultivated the Tao and its attributes, the chief aim of his studies being how to keep himself concealed and remain unknown" (quoted by Legge). This represents seeking a high moral order by imitation of the still-standing and unknown quantity -- eventually identified as "Heaven" even by the Confucianists -- behind the dome of the stars which had made such a sweeping change in 685 BC.

Confucius, born in 551 BC, must have been aware of the change, even though it happened 100 years before his time. However, it is not mentioned in any of his writings. To us, the most important works of Confucius were his compilation of ancient records, his preservation of a thousand years of poetry, and his annotation of the *I Ching*. But to Confucius himself, his most important work was the compilation of a year-by-year political record of his home state of Lu, the *Spring and Autumn Annals*, covering the years 722 BC to 481 BC. He specifically noted the importance of the *Spring and Autumn Annals*, working on it until shortly before his death. This period was also a time of internecine struggles among the nearly independent states, and the Confucian Annals have given their name to this period of Chinese political history -- the "Spring and Autumn" period.

His students and followers knew how Confucius felt about the *Spring and Autumn Annals* and elevated the book to the status of one of the five Confucian Classics. Yet the contents lack any philosophical observations and the entries relate activities which are all too terse and mundane to be of any interest.

If Confucius was searching among historical data for the effect of the change in the zodiac, it does not show. An inspection of the *Spring and Autumn Annals* yields nothing of note during the years spanning 685 BC. Some 37 eclipses of the Sun are listed for the complete period, of which all except two were verified in the 19th century. Five floods are listed, four earthquakes, three comets, three lightning strikes, and many rains of excessive magnitude.

The *Spring and Autumn Annals*, and the commentary by Tso Kew-ming, the *Tso Chuen*, are instead totally absorbed with the human failings of the leaders -- issues of honor, insults, and reputations.

China at that time was an inland nation, with the coastal regions held by "barbarian" tribes. Thus China did not use the stars for navigation, as the Eastern Mediterranean did. Little attention was paid to the stars or the planets, which to the Chinese did not represent earlier Gods. For example, when a large comet appeared in 524 BC the recommendation by the priests and court historians to perform extra sacrifices to avoid disaster were ignored. An earlier solar eclipse in the same year was accompanied by similar recommendations and response (from the *Tso Chuen*).

Frances FitzGerald, in *Fire in the Lake* (1972), details the outlook of the people of Viet Nam in recent times as a conservative Confucianism with the deeply imbedded elements of the Tao. The politics and social order for the Viet Nam "way of life" -- what FitzGerald calls "state of mind" in her first chapter -- are essentially Chinese, 2000 years old, rational and pragmatic, and so astoundingly different from European and American thinking and outlook as to be virtually incomprehensible.

Note 10 --

From the introduction to the *Zend-Avesta*, by James Darmesteter, in *Sacred Books of the East*, Volume 4 (1880):

"The world, such as it is now, is twofold, being the work of two hostile beings, Ahura Mazda, the good principle, and Angra Mainyu, the evil principle; all that is good in the world comes from the former, all that is bad in it comes from the latter. The history of the world is the history of their conflict, how Angra Mainyu invaded the world of Ahura Mazda and marred it, and how he shall be expelled from it at last. Man is active in the conflict, his duty in it being laid before him in the law revealed by Ahura Mazda to Zarathustra. When the appointed time is come, a son of the lawgiver, still unborn, named Saoshyant, will appear, Angra Mainyu and hell will be destroyed, men will rise from the dead, and everlasting happiness will reign over the world."

The Persians only used open fires as altars. Fire altars were in use for sacrifices to the Gods since remote antiquity in China, Central Asia, and India. These are modeled on the "fire on a platform" seen in the sky after 4077 BC when Saturn went nova. In Western Asia, Eastern Europe, Mesopotamia, and Egypt the image of Saturn in the sky is understood as a house instead, and temples are built as houses for the Gods.

Note 11 --

The celebration of Dionysus formed the basis of Grecian theater. As is noted by Alfred de Grazia in *The Disastrous Love Affair of Moon and Mars* (1984), it consisted of the introduction of a folk art form into an unformed society of survivors of the destructions of the 8th and 7th century BC.

"The theory of causation seeks evidence of abrupt takeover of a destroyed culture by marginal survivors who cast aside, or employ ceremonially, practices they do not or cannot use or understand. Then they proceed to draw from every source their new synthetic culture."

"... when the Greek theater appeared [writes Giovanni Patroni], we find the rustic god Dionysus, with a goat-cult of dancers cloaked in skins. The poverty of the means, the few actors, the vagabond origins of the Thespian theater, all showed still, according to Patroni, that the primitive real Greek theater was not receiving the subsidies of princes, not the interest or participation of Mycenaean high society; it was left to the rural folk. ... In the general destruction of societies, the art of the survivors made its way quickly forward. The elite and its sophisticated art forms were destroyed; folk art (not primitive art) dominated the scene."

-- Alfred de Grazia

Note 12 --

See Kelley L. Ross at [\[www.friesian.com/upan.htm\]](http://www.friesian.com/upan.htm). He continues with the following (describing the transfer of ideas some 700 to 900 years later):

"The undoubted transfer of ideas between Greece and India in the Hellenistic Period, and the export of Buddhism from India to China beginning in the Han Dynasty, provides us points of comparison with what, the uninfluenced traditions, came before."

[\[return to text\]](#)

Note 13 --

For a development of Greek philosophical systems from about 500 BC to about AD 200, see the first half of Charles Freeman's book *The Closing of the Western Mind* (2005). Later chapters detail the rise of Christianity after Constantine, up through the time of Aquinas.

[\[return to text\]](#)

Note 14 --

Livio Stecchini reports that a change to a differing dating system was initiated in Greece and Rome after 747 BC without reference to concurrent changes in Mesopotamia. See *The Velikovsky Affair* (1966).

[\[return to text\]](#)

Note 15 --

"It [the Miletian school of philosophers] set about to explain these phenomena [lightning, earthquakes] in terms of the same elemental processes ... as it invoked to explain the orderly arrangement of the earth and the heavenly bodies. In so doing, it implied the baselessness of the traditional Olympian religion which attributed lightning and earthquakes to whims of Zeus and Poseidon and world-destructions to battles of the sky-gods."

-- William Mullen, "The Agenda of the Milesian School" *Natural Catastrophes during Bronze Age Civilisations*, SIS Conference, (1997).

Thales of Miletos (640 -- 546 BC) is traditionally held as the first Greek rationalist investigator, based on his total rejection of the role of the Gods in creation, and his conclusion that everything was made from water (attributed to Thales by Aristotle). We see this as the first primitive atomic science. But consider the fact that, with this statement, Thales is repeating the oldest creation myths, which hold that everything indeed was made from water.

The measurement of the year and the rationalization of the periods of the Moon is also attributed to Thales. Apocryphally, to Thales is attributed the advice to navigators to steer by Ursa Minor, rather than the traditional Ursa Major.

[\[return to text\]](#)

Note 16 --

The circumference of Earth was found by Eratosthenes by measuring the length of a shadow in Alexandria at noon on the solstice, when it was known that, at the same date, the Sun was directly above Syene (Aswan). The distance between the two locations, at almost the same meridian, was known from Egyptian surveying records and probably accurate to within a few hundred feet. The most generous measure of his estimate for the circumference, 252,000 "stadia," based on an appropriate selection of a "stadia" (there are three differing measures for "stadia"), is 24,662 miles, which is within 198 miles of being correct -- and despite the fact that Syene and Alexandria are not at the same meridian, and that Syene is not located exactly at 23.5 degrees north. See Justin Pollard and Howard Reid, *The Rise and Fall of Alexandria* (2006). This book is a wonderful compendium of ancient science and philosophy, covering 330 BC to AD 650.

Robert Crease, a historian of science, writes in *The Prism and the Pendulum* (2003) about Eratosthenes,

"Eratosthenes's picture of the cosmos [a model] was critical to the success of the

experiment. Without this particular picture, measuring the shadow would not yield the earth's circumference. For example, an ancient Chinese cartographic text, the 'Book of the Masters of Huainan' [139 BC], notes that gnomons of the same height but at different (north-south) distances from one another cast shadows of different lengths at the same time. On the assumption that the earth is essentially flat, the author attributed this difference to the fact that the gnomon casting the narrower shadow is more directly under the sun, and argues that the difference in shadow length can be used to calculate the height of the sky."

This would have worked, but would not have resulted in a useful model, for the statements above are based on the concept of Earth as a flat plane.

The "picture of the cosmos" in Eratosthenes's time was derived from Aristotle: the Earth as a globe. It is one of the "narratized mental spaces" mentioned in the text, and it need not be a valid point-for-point representation of reality, as many models of physics will testify. Appropriate results from the exploration of this mental space are the only criterion for usefulness.

[\[return to text\]](#)

Note 17 --

For elements of statistics and probability theory in the context of their historical development which parallels common attitudes toward chance, see Michael Kaplan and Ellen Kaplan, *Chances Are* (2006).

The Greeks also developed the concept of the soul as a separate entity, which leaves the body on death and continues a life of its own. The concept was taken up by a number of writers and philosophers in Greece, first used in the sense of a transmigration of the soul. The idea of the existence of the "soul," unlike the idea of "free will," quickly spread to other cultures, introducing itself into the thinking of the Middle East and Alexandria, and was readily adopted by Christianity.

"Life after death" was not a common Greek concept in the period before the current era. A "land of the dead" was, however, interpolated into both the *Iliad* and the *Odyssey* after 500 BC, and achieved its modern definition with Plato after 400 BC.

The Romans did believe in the concept, and as a result developed a much higher social morality. But it was apparently already an accepted concept among the tribes north of the Alps (if we go by the medieval legends of the Celts).

Note 18 --

Not that there are not some very strange things reported by BLT Research, especially with

Robbert van den Broeke.

[\[return to text\]](#)

Note 19 --

It could be suggested that adding a series of posts or megalithic stones would help in concentrating the incoming (or "outgoing") plasma to the same location, and hence the building of henges. But this contradicts my earlier supposition that the number and location of the posts or stones replicated the look of the plasma stream seen incoming from the sky overhead. Henges were mostly abandoned after 3000 BC.

[\[return to text\]](#)

Note 20 --

I have seen suggestions of "plasma" on crop circle web pages, but they are often presented as some form of air disturbance and in terms of magneto-hydrodynamic fluid flows. See an article "The Physics of Crop Formations" (1998), by John Burke, at [\[BLT\]](#), which suggests plasma discharges as the cause (although Burke has not much of a handle on the mechanics of either plasma or electricity) and traces the original suggestion to George Meaden's book *Circles from the Sky* (1991). Meaden is a meteorologist and physicist.

[\[return to text\]](#)

Note 21 --

Robert Boerman, a Dutch author, wrote to me in an email in 2008:

"I have studied the crop circle phenomenon for 11 years from 1997. I visited, researched, photographed, measured and studied almost every single Dutch crop circle from 2000 to 2006, wrote two books about it, and now, after all those years of research, I don't know it anymore. The phenomenon is too complicated. What I found out is that there is a link between plasma (balls of light?) and crop circles. And I think that some of the crop circles are formed by nature itself, some by human mind, some definitely by hoaxers."

Boerman was the first to make me aware that he and other people were considering crop circles as a plasma phenomenon. See his website at <http://www.dcca.nl/index.html>.

The Sibylline Star Wars

The information below bears on the blazing of Venus and Mercury in 685 BC, the relocation of the polar axis, and the change in the location of the equinox. It is from a document written 800 years later, but clearly from extant sources. It is probably also the most spectacular confirmation of the reality of the events of 685 BC.

Franz Xavier Kugler, an early 20th century translator of Babylonian cuneiform astronomical tablets, in a book titled *The Sibylline Battle of the Stars and Phaethon Seen as Natural History* (1927), analyzed the ending of the fifth volume of the Sibylline Oracle Books, originally completed (it is today estimated) in about AD 115 in Egypt. He suggests that the text deals in specifics, of a yet-to-come event, for which details were garnered from older records, although in his opinion the details date from 1500 BC. In my opinion the details date from 685 BC.

The *Sibylline Oracle* books were written in Greek in lower Egypt between 100 BC and AD 200. They are mostly Jewish in sentiment and philosophy, as they are in politics. Using an established style for prophecies, as in the Delphic oracles and in the writings of the prophets of Israel, "Babylon" is substituted for Imperial Rome, while "Rome" might be a substitute for the real name of an Emperor. This makes interpretation difficult at times. The Books were still in circulation in the 16th century as manuscripts. German and English translations (from the original Greek) appeared late in the 19th century.

Livio Stecchini, in "Cuneiform Astronomical Records and Celestial Instabilities" in *The Velikovsky Affair* (1966), reiterates Kugler's idea that the Sibylline prophecies were based on extant data from antiquity. He also notes that the scientific philosophies which had developed by this time (100 BC to AD 100), required specifics in prophecies. There are additional comments by Malcolm Lowery in the article "Father Kugler's Falling Star" in *Kronos* (1977),

and by Bob Kobres in "The Path of a Comet and Phaethon's Ride" in *The World & I* Volume 10, No. 2 (1995). Stecchini writes, about Kugler:

"Kugler wanted to indicate that the writers of the oracle were so preoccupied with solid astronomical facts that they described the successive phases of the episode of Phaethon according to what they knew about the position of the heavenly bodies in the several months of the year. It is his contention that the writers of this oracle, far from being maniacs breathing gibberish, were trying to make their prediction (based on a past historical occurrence) credible by framing it in an accurate astronomical timetable."

Stecchini then continues to promote his own viewpoint:

"This group of philosophers was fathering modern uniformitarianism, because they were fitting the historical tradition of 'catastrophes' into a cyclical pattern of phenomena recurring at fixed intervals of time, past and future, according to an absolutely unchangeable and predictable order of the heavenly cosmos."

That is so modern to say. The "unchangeable and predictable order" is totally missing. Just read the poem once and you will be convinced. I also disagree with the date of 1500 BC, as if some celestial disruption happened at that time, for it is doubtful if such detailed data was recorded that far back, or that it would have survived as astronomical data, when the social milieu of that remote time still held fast to attributing all such events to the Gods. And I do not think we could hope for a clear calendrical record if the land had been devastated repeatedly and the skies were obscured for years. Much more likely the specific data records the blazing of Venus in 685 BC. By 685 BC, Babylonian astronomical records had appeared and observation of the heavens was well established.

The Great Year

I should first note a related numismatic oddity among the coins of the Roman Imperial period. This involves the reverse side depiction of an upfacing crescent with seven stars above. These occur in the reigns of the Roman emperors Hadrian (reigned AD 117 to AD 138), Commodus, reigned to AD 192, and the Severan dynasty (AD 193 to AD 235) with dates late in the second century AD and early third century. These coins thus coincide or closely follow the writing of the Sibylline Star Wars text. [\[note 1\]](#)

I looked at hundreds of coins from the Roman Imperial era. All the coins depict a head (generally the emperor) in profile and the scene of a full-sized figure on the reverse -- at times mythological, at times as allegorical personifications (Victory, Africa), at times a temple structure or sacrificial devices. One even shows the double-ended triple-tined thunderbolt of the Eastern Mediterranean on the side of a cart drawn by four horses. There are also infrequent depictions of a star within an upturned crescent. In one case this is sitting directly above a pillar of sorts.

There are also some Parthian coins with the crescent and seven stars of the same dates. And then, after the third century AD, it fades, except for occasional uses into the current era. In antiquity Isis, holding baby Horus, is shown standing on the crescent with seven stars surrounding her head, as Mary holding baby Jesus is today.

[Image: Roman coin of the Imperial era after Hadrian.]

Curtis L Clay, posting at <http://www.forumancientcoins.com/board>, in November, 2005, writes, with respect to Roman coins with a "crescent and seven stars" design on the reverse:

Strack, noting that the same type is labeled SAECVLI FELICITAS, "The Happiness of the Age", on Eastern denarii of Septimius Severus [reigned AD 192 to AD 211], interprets Hadrian's type as indicating the return of the seven movable heavenly bodies to their original positions, signaling the beginning of a new golden age.

He cites: (1) Festus: "The mathematicians call it the Great Year when the seven wandering stars complete their individual courses and return to harmony with each other", and (2) Servius [4th century Roman grammarian] on Virgil's Eclogues: "At the completion of the Great Year all of the stars return to their places and begin the next cycle of identical movements. If the movements of the stars are repeated, it follows that everything that happened will recur again, since it is obvious that everything is determined by the motions of the stars. For this reason Virgil says that the Golden Age will return and everything that happened before will be repeated."

I cannot find the related text in Virgil. Clay continues with:

On this interpretation, we have to assume that the moon is depicted twice in the type: it is represented not only by the crescent, but also by one of the seven stars above the crescent, since it is one of the seven wandering heavenly bodies, but is also by far the most prominent of them at night, and the only one that waxes and wanes.

But I suspect that the Moon is *not* depicted twice. The upturned crescent has nothing to do with the Moon. Although the seven stars are grouped in various ways to reflect graphic convenience and representative shorthand, the crescent is always shown as upturned -- a

condition which the Moon never achieves, except in the tropics.

The crescent is the backlighted portion of Saturn, last seen in 3147 BC. It has no significance for 2349 BC or 1492 BC, or for June and July of 685 BC, except to signify the endpoint or the start of creation -- the destruction of the heavens. The grouping together of all the planets was still remembered or understood as significant from before 3147 BC, although during the "Era of the Gods" the seven objects grouped together were probably the satellites of Saturn. In the third century AD these were the seven planets. The crescent below the stars is part of the standard depiction, and has nothing to do with the Moon.

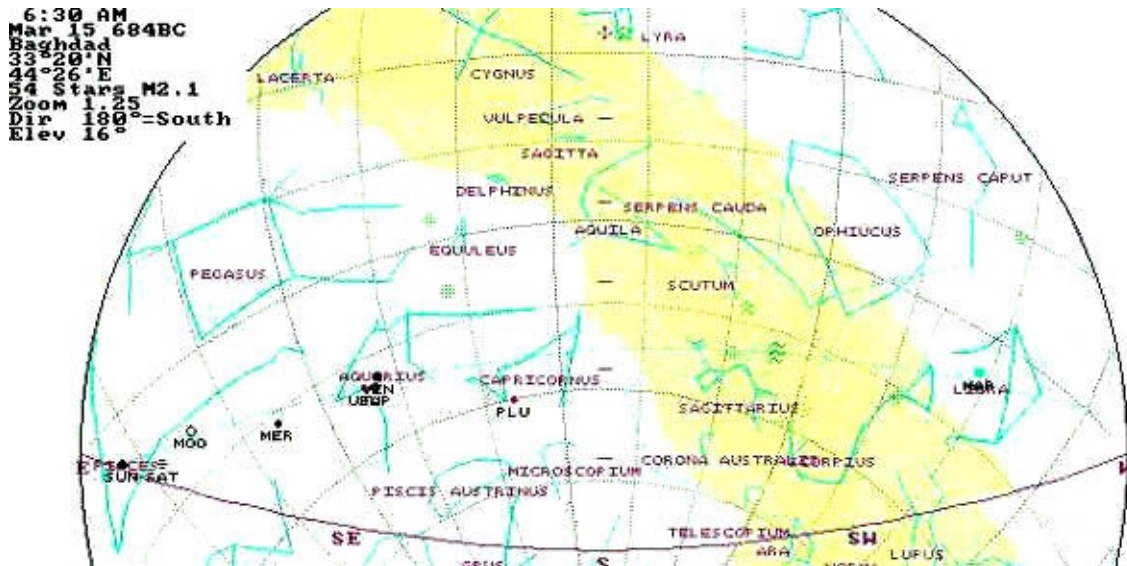

This idea of "grouping together" and the start of a new epoch was reinforced at the beginning of the calendar year following the nova event of 685 BC. In spring of 684 BC, on the day of the equinox, all seven planets presented themselves in the eastern sky just before sunrise.

On March 8th, Gregorian (the equinox in the previous era), the planets extending from the east horizon were: the Sun (before rising), Saturn, the new crescent Moon, Mercury, and Jupiter and Venus (almost conjunct), then a large gap and Mars over the southwest. The first six were all grouped in two houses, Pisces and Aquarius. Geometrically the center of the distance between the Sun and Mars is located in Capricorn.

Berosus

Berosus, a priest from Babylon who moved to Greece after 300 BC, had noted that planets in Capricorn of the Great Year are associated with a deluge, and when these appeared in Cancer the catastrophe would be fire.

In the previous year -- the year of the nova event of 685 BC -- early in June (June 15, Gregorian) the planets Venus, Mercury, plus the Moon, Sun, and Mars straddled the constellation Cancer (all within 45 degrees). This was the starting day of the blazing of Venus and Mercury. This may be the reference to Cancer which Berosus had in mind. Jupiter and Saturn were nowhere near, however.

[Image: The sky on March 15, 684 BC, Julian, the signs in the sky of the first "Great Year" after the plasmoid of 685 BC. From SkyGlobe 3.6.]

I should note that March 8, Gregorian (March 15th, Julian), is the "old date" of the vernal equinox, which had moved to March 21 in 684 BC, as I have shown elsewhere. This was the first instance of the new date of the spring equinox (although using the old calendar date). The conjunction was also not a unique event. By the end of the same year another conjunction showed up on December 15th: the Moon, Saturn, Jupiter, Mars, Venus, Mercury (these two both in Capricorn) and the setting Sun.

The initial conjunction includes all the elements of the "Great Year" from antiquity: a long interval between catastrophic destructions of the world (as it was assumed), the grouping of all the planets so that they would restart their orbits, the first day of the first year in the new era (at the conclusion of the previous era), and, lastly, the identification of the start of the Great Year with the constellation Capricorn.

van der Sluijs

Marinus van der Sluijs, in "A Possible Babylonian Precursor to the Theory of Ecpyrosis," *Culture and Cosmos* (2005), in an analysis of a Babylonian text *Erra and Isum*, suggests a precursor to the concept of a Great Year as shown in the poem's dialog between Marduk (Jupiter) and Erra (Mars). Mars has usurped Marduk's power but relents after being warned how the world will end with fire if he persists. It does, of course, nearly end with fire, although in 685 BC Marduk (as Jupiter) takes control again.

The narrative compares the "water catastrophe" of Marduk with the "fire catastrophe" of Erra -- as if these two directly followed each other. They did not, of course, as we know. The fall of the Absu in 2349 BC would be the "water catastrophe," but the Exodus event intervened.

The crucial details of a common element allowing for the comparison, and the reason for selecting the 2349 BC "fall of the Absu" event rather than Exodus, is that in both instances, 2349 BC and 685 BC, Jupiter (Marduk) is involved in an identical gesture -- he gets up from his seat, then sits down again. The moment he rises, creation starts to come undone.

"Getting up from his throne," in the *Erra and Isum* narrative is an up-country version of the same incident recorded in the Babylonian *Enuma Elish*: the disappearance and reappearance of Marduk's garment. In both cases -- in the *Enuma Elish* and in *Erra and Isum* -- this was the disappearance of the lower mountain-shaped plasma expulsion of Jupiter. In these two instances, in 2349 BC and 685 BC, as I have detailed already, there was the sudden reappearance of the lower coma expulsion or "throne" of Jupiter after the catastrophe -- as if to suggest that the act of reseating Jupiter stabilized creation. The sequence in both cases is extensive because the time lag between unseating and reseating is measured in decades or centuries, but a causality was affirmed.

This is among the details brought forward by vd Sluijs, although without reference to actual events and dates, which he is unaware of. We possess only portions of the narrative, and thus we do not know how the conflict between Jupiter and Mars was resolved, although we could guess. The *Erra and Isum* text is thought to be dated to the period of 1200 BC to 600 BC. Because of the revolt by Mars and the warning of devastation to come, I would opt for a creation date for the document after 650 BC.

What we have here is an example of myth creation (narratization) for two historic events which identify the agents involved. We know both the events and the protagonists, having met them already in the text I have so far presented. Most interesting is that the author is willing to tie together events 1500 years apart with the single gesture of the reseating of Jupiter. The reseating we know of already also. The number of years between these events is certainly much longer than the 684-year span of the Great Year as suggested directly below.

Even in antiquity (as we know from texts in the first century AD), the length of the Great Year was in question. Why this was so will soon become clear. There are some obvious values for the span of time of a Great Year which could be calculated. Some are patently obvious.

Clube and Napier

Victor Clube and Bill Napier, in *The Cosmic Serpent* (1982), use a Great Year of 684 years. It is a value based on B.L. van der Waerden's *Science awakening II: the birth of astronomy* (1974). Van der Waerden found this as a frequently encountered number in ancient Babylonian sources. Clube and Napier go to some rather extensive numerological contortions to pick up a time span of 684 years. They use the date of the second Earth shock (686 BC) identified as due to Mars by Velikovsky, along with a made-up date for the Exodus, 1369 BC, to fit the time span of 684 years (counted inclusively), and use it to suggest that the next

catastrophe would be in 2 BC.

This is based on the fiction of a new date for Exodus, which, however, is not needed. The span between the more generally accepted date of 1492 BC for the Exodus, and the first "attack" by Mars in 806 BC (which Clube and Napier were not aware of), spans 686 years -- close enough to van der Waerden's (and the Babylonian) value of 684.

What is interesting, of course, is that the Babylonians were attempting to impose some order to the planets in the sky. The dreadful 120 years of assaults by Mars were real, and were remembered. So were the 684 quiet years which preceded that period. The date of 2 BC might have been viable for a long time as forewarning of another catastrophe, but apparently nothing happened.

I looked for 7-planet conjunctions between 7 BC and AD 1 (Julian astronomical dates, thus to AD 4), checking month to month during the time of a new Moon. These conjunctions are not uncommon. A list of the five found during this 8-year period is shown in the endnotes.

[\[note 2\]](#)

It is likely the Babylonian astrologers did not use Clube and Napier's math to obtain the number 684. But, assuming "684" was indeed known and was correct, then adding 684 years to 806 BC (the first time Mars devastated the Middle East) will result in scheduling the next catastrophe for the year 122 BC -- when also nothing happened. But adding 684 years to 685 BC makes the next event fall in 1 BC. The dates are astronomical, so that 1 BC represents AD 4 in Eastern Mediterranean chronology. Either date will do.

Hadrian

Meanwhile, conjunctions just kept on coming, without any apparent catastrophic effects. I checked, but no conjunction happened anywhere near the death of Julius Caesar, despite his deification in response to a sighted comet. I also started to check for the time period of the emperor Hadrian from the year AD 100 on. Conjunctions of all the planets spread across the sky happen on the following Julian dates (I may have missed some).

- AD 107, Sep 19, Moon (rising), Sat, Mar, Mer, Ven, Jup, Sun (setting)
- AD 109, Oct 27, Moon (rising), Mar, Sat, Ven, Jup, Mer, Sun (setting)
- AD 115, Jun 5, Sun (rising), Jupiter, Venus, Mercury, Saturn, Mars, Moon.

[Image: The sky on June 5, AD 115, Julian (AD 119 in Eastern Mediterranean chronology). From SkyGlobe 3.6.]

The last of these (AD 115) corresponds to AD 119 in Eastern Mediterranean chronology. Hadrian became emperor in AD 117, two years before this conjunction. The first coinage of the crescent and seven stars occurs in AD 119 or 120, although I have not been able to verify this from other sources. Hadrian was in Britain at this time, busy with Hadrian's Wall.

I would suggest that the frequent conjunctions were worked into the propaganda of political discourse. The Romans were acutely aware of astrology, and nothing would have been missed. Additionally, the future locations of the planets in the sky could at this time be accurately calculated in advance. [\[note 3\]](#)

"There was an obsession with astrology," writes Tom Buggey, "during the reign of Septimius Severus and successors, the reliance on astrology became a mania." (At <http://tjbuggey.ancients.info>.) Buggey means the Severan Dynasty, AD 193 to AD 235, which followed directly after the emperor Hadrian.

In AD 126 Hadrian completed the building of the Pantheon in Rome -- the temple to all the Gods, all seven -- an absolutely magnificent and sturdy building, which still stands today. On June 30 of astronomical year AD 122 (which is AD 126), there was a clear conjunction (another "Great Year" lineup) with Jupiter in Sagittarius in the southeast, Mars and the new Moon in Libra, and Venus, Saturn, and Mercury in Leo, with the Sun setting in the northwest. All the Gods stood in the sky. Perhaps dedicating the Pantheon at this time had prevented the end of the world.

Stecchini

It thus seems likely that the prophecies of the *Sibylline Books* accomplish what Livio Stecchini proposes, that is, to present a "cyclical pattern of phenomena recurring at fixed intervals of time," even though Stecchini offers no indication of the measure of the repeating cycle. Stecchini wrote, paraphrasing Kugler:

"It appeared in the east sky more brilliant than the Sun,"

He writes, additionally:

"The lines purport to describe the circumstances of the coming end of the world; they were written in the century before the birth of Christ [but collated with other texts in the second century AD] by Greek-speaking inhabitants of Egypt, when the ancient world was agitated by the Messianic expectation of a cosmic upheaval. But the lines give an account that is so exact and technical that it must be something more than a mere mystical vision of coming destruction. Such precise astronomical details are given that, calculating by the position of the constellations around 100 B.C., the crisis began in September and reached a climax in seven months ... after the 7th or the 8th of April."

"... According to Kugler, the crisis described as the Battle of the Stars began with the appearance in the eastern sky of a body as bright as the sun and similar in apparent diameter to the sun and the moon. The light of the sun was replaced by long streams of flame crossing each other."

"After the mention of these streams of flame that replaced the sun as a source of light, there follows the line, 'the Morning Star fought the battle riding on the back of Leo.'"

Stecchini explains, after Kugler, that "Venus [the Morning Star] riding on a lion" was a well known and "feared emblem for disaster" in the Eastern Mediterranean region, and gives examples of unconnected goddesses all depicted as riding on lions. I would point out, of course, that the "emblem" was well known because it had been experienced in 685 BC. Phaethon appeared not in remote antiquity, but in 685 BC. And the "Morning Star" was not Venus, but Mercury.

In the Star Wars description we again find Jupiter (Zeus) coming to deliver a mortal thunderbolt, as in the "legendary" event of Phaethon. Although in our current concepts of the solar system the honor of being the Morning Star goes to Venus, in 685 BC, and since the prior year already Mercury was the Morning Star.

There is no question that the Phaethon legend describes the nova event of Venus and Mercury in June and July of 685 BC, although the Roman author Ovid (before AD 17), who narratized the "legend," places all the action in the span of one day rather than 40 days. Some descriptive details stand out. Ovid notes that large regions of the Earth were burned up with "*Ignis Coelis*" (fire falling from the sky), that Phaethon had to struggle against "the whirling poles" (which may have been a reference to a polar plasma plume) and was swept away by the "swift axis" (the polar axis?), that the normal path of the Sun through the skies was not followed, that the northern constellations attempted to dip into the sea (as the equatorial moved), and ends with the note that the Earth "sank back a little lower than her wonted place" (as paraphrased by Velikovsky).

Plato (circa 300 BC) quotes Solon to the effect that Phaethon's ride ended when he was hit with a thunderbolt delivered by Jupiter. Hesiod (circa 650 BC) mentions the birth of Phaethon to Eos (Dawn) and his abduction by Aphrodite (Venus). Phaethon is Mercury. Aphrodite here is the planet Venus, not the Moon.

A year earlier Mercury had been involved in a plasmasphere contact with Earth which had reduced its orbit to fall entirely within the orbit of Venus. With this in mind, his "birth" as a Morningstar -- "the child of Dawn" -- plus his spectacular "abduction" by Venus will start to make sense.

Mercury's abduction is the near conjunction of Venus and Mercury on June 15th of 685 BC. It was seen as an abduction (also understood as a birth) because Mercury had previously only been seen just above the horizon before sunrise or after sunset (four times a year). It would not have been seen as traveling across the sky with the Sun, except that on June 15th, while very near each other in the sky, both Venus and Mercury started to blaze like suns during the day.

The two planets looked like comets, with shafts of light streaking across the sky -- directed both toward the sun and away from it, and likely at right angles as well. This is what comets do under the electric stress of approaching the Sun. Later astronomers, inspecting ancient records, came to the obvious conclusion that comets are generated when planets meet in conjunction. This opinion was held from Roman times through the Middle Ages.

A Starting Date

My estimate, made before I ran across the text by Stecchini, was also of an initial appearance in the east and a course of 8 months. Originally I selected a period starting in March/April and lasting to January of the following year (rather than Kugler's September to April of 100 BC). At the first writing of this text I had no idea at all of when Venus would first have started to blaze, and used the first date of its appearance in the east, going by ephemeris information. Only in early 2008 did I manage to derive a reasonable set of dates for the event, based on diverse records. At this time I would hold that the blazing of Venus started on June 15, Gregorian, and ended on July 25th Gregorian (June 22 to August 1, Julian). The general details of these two dates were presented in a previous chapter and in the chapter "The Chilam Balam Books.") Finding these dates simplified a reading of the *Sibylline Oracle* texts, which I will address below.

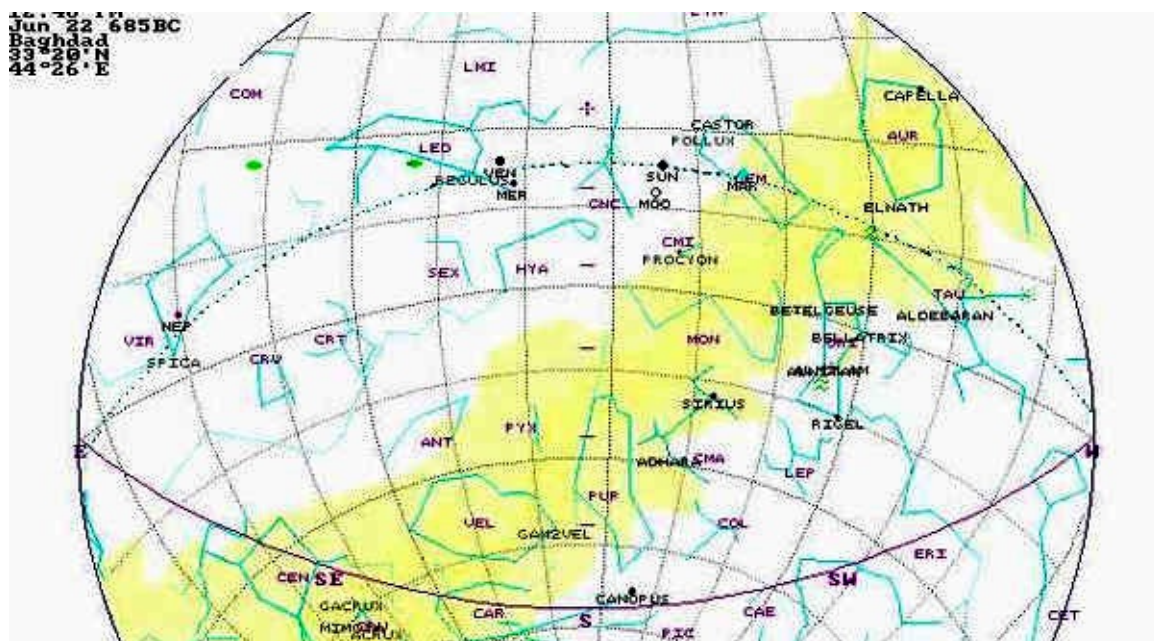

What is of greater interest are the specifics of the prophecies, not the dates. I disagree with Stecchini's evaluation (after Kugler) that the information "is so exact and technical that it must be something more than a mere mystical vision." I should explain that Kugler sees the progression of the Sibylline description as simply recording the path of the Sun between September and April. This becomes the basis for his assumed Phaethon event of circa 1500 BC by inference (which was actually the Typhon event, and points up how little is really

known of the Exodus).

What I see, instead of a play-by-play, is an opening and closing statement which encloses a long list of damages in terms of relocations of the constellations, which range over all except a few of the zodiacal constellations. The effect is not unlike the trail of constellated animals which follow the depiction of the killing of the bull (Taurus) in the temples of Mithras, or the list of celestial damages presented in the play *Thyistes* by Seneca. Both of these are contemporaneous with the Sibylline prophecies.

There is an opening statement: the account of the visionary, how the star-war progressed (at which point dates come into use), what the main weapon was, and a summary of the lasting damages. At the end of the text we find a resolution and a windup signifying the end of creation. Enclosed by these is a long list of alterations in the constellations of the zodiac (and some others), which are neither complete, nor make all that much sense except when the new skies are compared with the old skies. But I suspect that the list was not meant to be complete; the main purpose was to suggest the utter derangement of the stars resulting from the battle.

For Kugler to have used 100 BC is reasonable, since in 1927 it was the best guess for a date for the Fifth Book, and since Kugler only sees an association with the normal path of the Sun. I will not pursue this. I am more interested in obtaining data for the actual event of 685 BC.

[Image: The sky on June 15, 685 BC, Gregorian. Looking south, at noon, a day of the new Moon. Venus and Mercury are in Leo, to the east of the Sun and Moon, which are in Cancer (CNC). (Not corrected for the change in the Earth's axis.) From SkyGlobe 3.6.]

The location of the planets and the constellations with respect to each other remained the

same before and after 685 BC, but the polar axis and the equatorial both shifted. The constellations all appeared in the skies in the wrong places, that is, in the wrong locations with respect to the horizon and the zenith of the earlier ephemeris. Additionally, the starting date of the year (the vernal equinox) after 685 BC had shifted 15 days into the future.

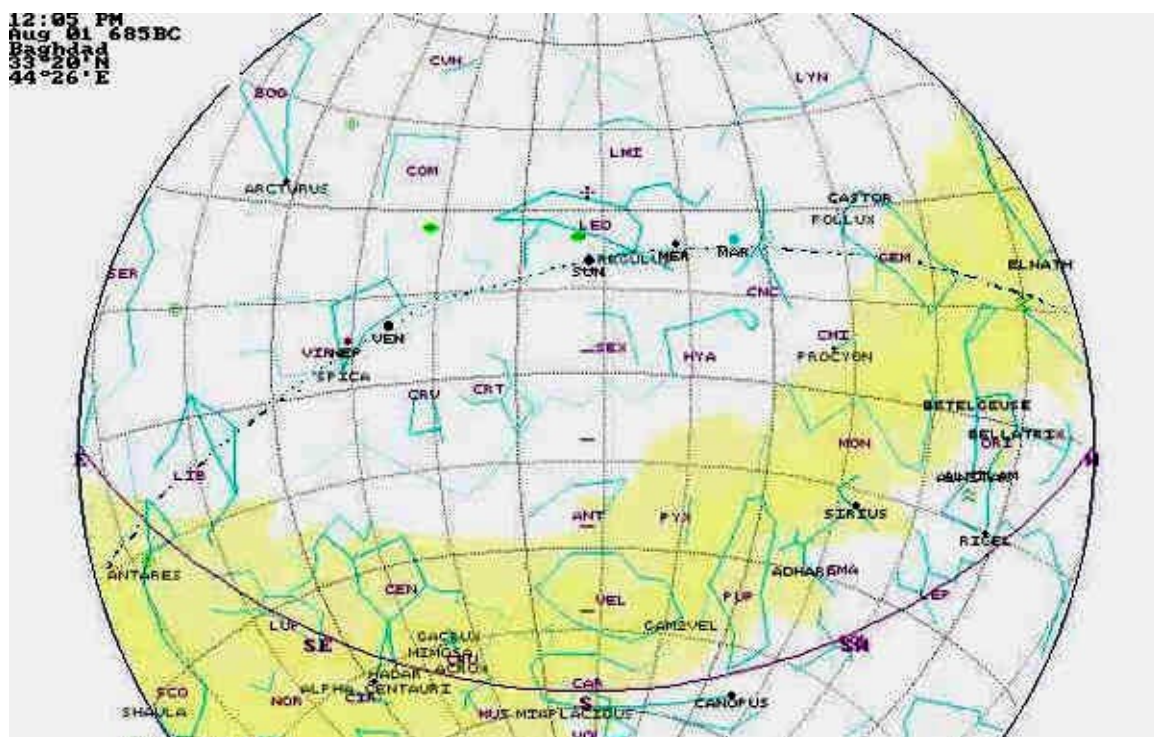

The Opening Text

The text in question, representing lines 688 through 711 of Book Five of the *Sibylline Oracles*, is from a translation by Milton S. Terry in 1899. The text starts with: [\[note 4\]](#)

*"I saw the threatening of the shining Sun
Among the stars,"*

*"and in the lightning flash
The dire wrath of the Moon; the stars travailed
With battle; and God gave them up to light."*

It is the Sun which is threatened by another body or bodies. The "travail of the stars" involves the relocation of the constellations of the zodiac after the battle is done. This becomes fact only after the 40-day battle is completed. More on this below.

[Image: The sky on July 25, 685 BC, Gregorian (August 1, Julian), the concluding day of the blazing. The Sun is in Leo, Venus is in Virgo. From SkyGlobe 3.6.]

"I saw ... in the lightning flash, the dire wrath of the Moon." The author here jumps to the

climax of the event, the delivery of the plasmoid lightning bolt of Jupiter on July 25th. Before July 25th (Gregorian), Europe and Asia had seen the bolt approaching from Jupiter for days. The bolt had passed directly by Earth on the day side, but only Mesoamerica had witnessed it at full size. On the 25th of July (August 1, Julian) the bolt was seen approaching Venus and the Sun.

As night fell, and Europe turned away from the path of the plasmoid in the day sky, nothing was seen except the Moon standing in the south, in its first quarter, probably after 9pm in the evening (it set at 1:30am). With the plasmoid traveling at an estimated speed of 40 million miles per day (64 million km per day) it would have reached the Sun in a half day after it disappeared from view to Europe. That is when the plasmoid hit the Sun. It would have been 3am in the Eastern Mediterranean.

The Sun rose the next day at 5am, engulfed in a cloud of plasma (to last an additional 7 hours as the 15-million-mile (24-million-km) long plasmoid crashed into the Sun), which also occluded Mercury, Mars, and perhaps Venus. Venus rose late, but may have lost its coma already, in which case it was not likely to have been seen.

I have previously proposed that the plasmoid would have had a diameter of perhaps 1.5 million miles (2.4 million km). That is twice the diameter of the Sun. The plasmoid would have engulfed the Sun. At an estimated length of 15 million miles, the flash of the first contact might have lasted 9 hours. The *Popol Vuh* suggests that additional smaller plasmoid bolts continued to arrive from Jupiter for four days.

It must have been seen all around the horizon, and the Moon, rising the next day in the east after 3pm, while the Sun was still engulfed in plasma, would have lit up spectacularly. This describes the concluding event.

"God gave them up to light" obviously is meant to poetically tell that the battle happened during the daytime, which agrees with ephemeris information, or that a lot of light was produced for days. The narrator now drops back to the beginning of the battle.

*"For long fire-flames rebelled against the Sun;
Lucifer treading upon Leo's back
Began the fight; and the Moon's double horn
Changed its shape;"*

The starting position is now indicated as defined by the text, "Lucifer treading upon Leo's back." This was "Venus riding on a lion," the well known and "feared emblem for disaster" in the Eastern Mediterranean region, as per Kugler. On June 15 (June 22, Julian), Venus and Mercury are in Leo, to the east of the Sun and Moon, which are in Cancer. Lucifer is Mercury, but could be Venus.

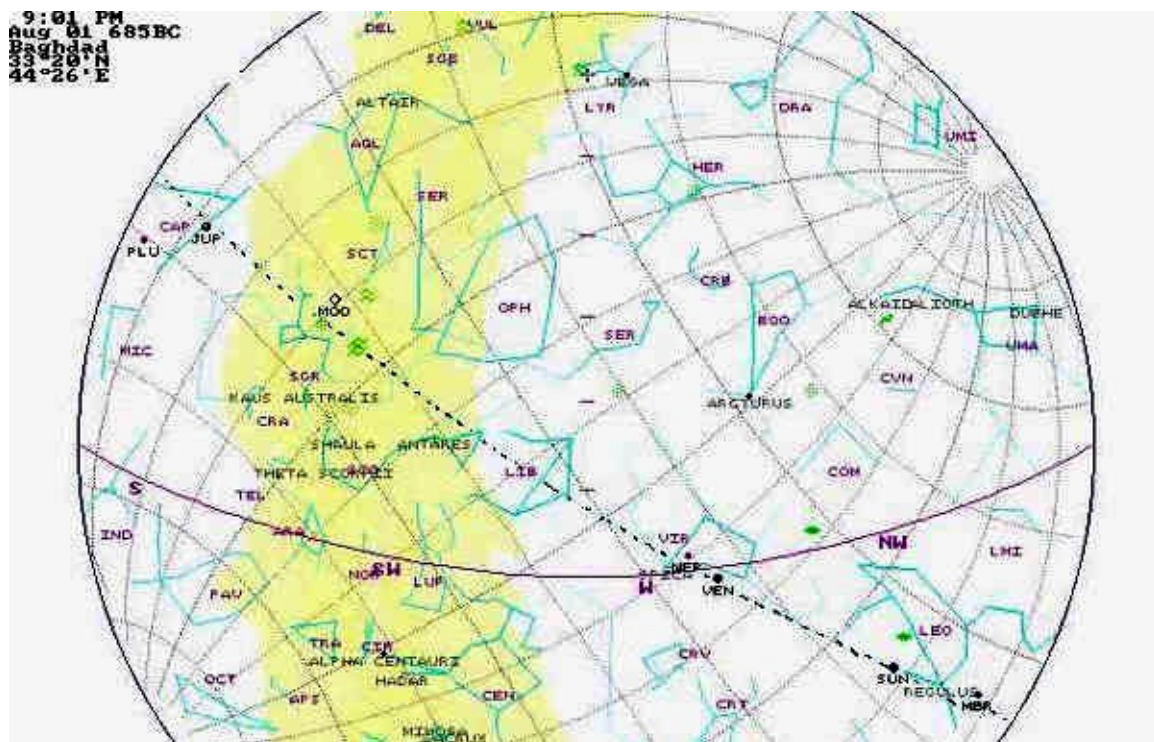

The "long fire-flames" are the plasma expulsions of Venus and Mercury (and somewhat later

also of Mars). The "long fire-flames" probably extended both away from the Sun and toward the Sun, as well as at right angles to these. This has been seen for comets. The crossed beams in the sky presented a triple crucifixion. Mercury, in the center, would have been recorded with his spiked crown. [\[note 5\]](#)

Before and after sunrise the "flames" would reach up from below the horizon. Stecchini writes of the plasma plumes as "long streams of flame crossing each other" (quoted from Kugler). Rising up from the horizon where the Sun has set, these are the pointed sticks planted in the ground by Kirkin (Venus). Jupiter (Wyju) jumps into the same section of the horizon about 6 hours later with both feet.

Almost at once after mid-June, Mercury starts to move toward the position of the Sun, and passes it by July 3 (July 10, Julian). At that point Mercury, also ablaze, might have sent streams of plasma directed at Earth, for being in front of the Sun, its plasma tail would have pointed at Earth.

The coma, the plasma expulsions, and the distorted view of the plasma tail of Mercury when it extended toward Earth (easily confused with the Sun which Mercury was close to), are described by Isaiah and Ezekiel.

[Image: The sky on July 25, 685 BC, Gregorian (August 1, Julian), the concluding day of the blazing, after about 9pm. The Sun and Venus have set. Sun in Leo, Venus in Virgo. Not shown is the plasmoid arriving from just below the western horizon. From SkyGlobe 3.6.]

I would also suggest, in fact, that if the two inner planets were in flames and Jupiter reacted similarly a half month later, then certainly the Earth also would have been subject to such a condition. Plasma expulsions from the Earth may have been seen moving up into space. In a previous endnote I wrote:

"... the Earth also would have ended up erupting, but because of the Earth's magnetosphere and enclosing atmosphere, the Earth might have been spared the creation of thousands of electric burn craters, as on Venus and especially Mercury. There is the contemporaneous statement by Assurbanipal, king of Assyria, about Ishtar (Venus) 'raining fire over Arabia.' Later Roman writers make the same claim of the Earth burning up because of the close approach of Phaethon, as does Plato."

The Moon (at night after June 15) would be lighted by the Sun, and the bright Venus and Mercury, so that its crescents ("horns") would be misshapen from its normal form. The Moon would normally have had sharp waxing horns after June 15. Now, with the blazing of Venus and its extended light, the horns might have reached further around the edges of the Moon, or the opposite edge of the Moon would have been lighted, "the Moon's double horn changed its shape."

During the days of the late summer, with the steep gradient of the zodiac, the plumes would point down at the horizon, since Venus would be below the Sun most of the day. Only late in the day would the flame become horizontal. After nightfall a stream would come up from below the western horizon at a 45-degree angle, lighting up a large portion of the night sky.

The image above is for 9pm of July 25 (Gregorian). It is the early night sky of the concluding event, as seen from the region of the Eastern Mediterranean. Jupiter's plasmoid lightning bolt is headed for the western horizon. In the diagram above the plasmoid travels along the circle of the ecliptic. As Europe turned toward the night, the bolt was seen approaching Venus -- thought by some to be the errant Phaethon -- to strike him down. In actuality the bolt passed by Venus and struck the Sun, but the contact was not seen. The plasmoid landed at the Sun at about 3am. The morning would see the Sun, Mercury, and Mars all engulfed in a haze. The *Popol Vuh* claims the turmoil lasted four days.

It is quite possible that the people of the Eastern Mediterranean got it right, and knew the thunderbolt struck Mercury, who was primarily identified as Phaethon. But an error remains, for the target was the Sun, not Mercury, which was within 11 degrees of the Sun. By next morning Venus and Mercury must have quieted down, although the skies remained obscured for days. [\[note 6\]](#)

Mesoamerica did not see the massive explosion at the Sun either, because it happened a few hours after sunset. It was assumed that the bolt was destined for Mars, standing just to the right (west) of the Sun (about 30 degrees). The explosion at the Sun would have visually engulfed the location of Mars in the sky, as well as Mercury. The next day the Sun was still in place, so it was assumed (at least by some of the many literate people of Veracruz and the

Valley of Mexico) that Mars had been hit. Mars did not again come close to Earth, but primarily because the orbit of the Earth became nearly circular (as noted by Rose and Vaughan) before the time that Mars might have returned again. (Assigned to 670 BC, in Eastern Mediterranean chronology.)

The Maya *Book of the Chilam Balam* states that the Sun left its normal path for three Uinal months of twenty days. This is counted inclusively, however. The actual period would be 40 days -- June 15th to July 25th, Gregorian. The *Chilam Balam* also places the arrival of the lightning bolt from Jupiter, which ended the affair, exactly on July 25, 685 BC (Gregorian), which may also be calculated (from the same text) from the last close pass of Mars 520 days earlier.

From the *Sibylline Oracle* it might be suggested that the end of the drama happened with the Sun and Venus both in Capricorn, which would have been January of the next year. The *Sibylline Oracle* reads:

*"Capricorn smote Taurus's neck;
And Taurus took away from Capricorn
Returning day."*

But this might also simply suggest the most obvious aspect of the list of changes which will have been wrought with the war -- the change in the equinox. Jupiter was in Capricorn when the plasmoid was released. So it was Capricorn (in the typically displaced wording of prophecies) that "smote Taurus's neck." The phrase "returning day" is the fact that Taurus has been shifted to below the horizon at the vernal equinox with the change of the zodiac, thus giving up some 15 days.

That prediction will be true for the coming years. Taurus's neck was broken, it would no longer be the constellation that the Sun rose in at the equinox. In the typical stylishly metonymical metaphor of the *Sibylline Oracle*, whatever "Taurus," the constellation, took away from "Capricorn," Taurus was giving up -- calendar days.

The wording, "smote Taurus's neck," is reminiscent of the Tauroctony of Mithraism, the slaying of the bull Taurus, depicted as having its throat cut. In antiquity the constellation Taurus was depicted only as the head of a bull, not the complete body, as is done today, which is also how the constellation was first depicted in the temples of Mithra circa AD 100.

Before 685 BC, with the Sun rising between Aries and Taurus at the vernal equinox, it is the head of the bull which was already (or soon was) above the horizon at the equinox. After 685 BC, with the Sun rising at 15 degrees of Aries at the vernal equinox (using the divisions of the ecliptic of antiquity), the head of Taurus no longer appeared above the horizon as the Sun rose to announce spring. His throat had been cut.

Capricorn is here the agent of change. Jupiter is in Capricorn throughout the 40-day period.

In early January of the following year the Sun and Venus were also both in Capricorn. By this time the blazing of these two planets had subsided long ago, and this condition probably has nothing to do with the lines about Capricorn (and despite my earlier note about Berossus).

The *Sibylline Star Wars* document is obviously based on an ordered record of changes, and the travels of Venus, but that is no guarantee that it correctly incorporates the starting and completion dates. [\[note 7\]](#)

The display in the sky is nicely wrapped up in the closing lines of the poem (I'll detail the center section below):

*"And the strength of the mighty Shining One
Aquarius kindled. Uranus himself
Was roused, until he shook the warring ones;
And being incensed he hurled them down on earth."*

"Shining One" translates to "Phaethon," and thus refers back to Mercury or Venus. But if it is Aquarius (the constellation) who "kindles the strength," then it was Jupiter who was invigorated. However, Jupiter is not in Aquarius during the 40 days of battle. In July Jupiter was in Capricorn, the next constellation to the west of Aquarius.

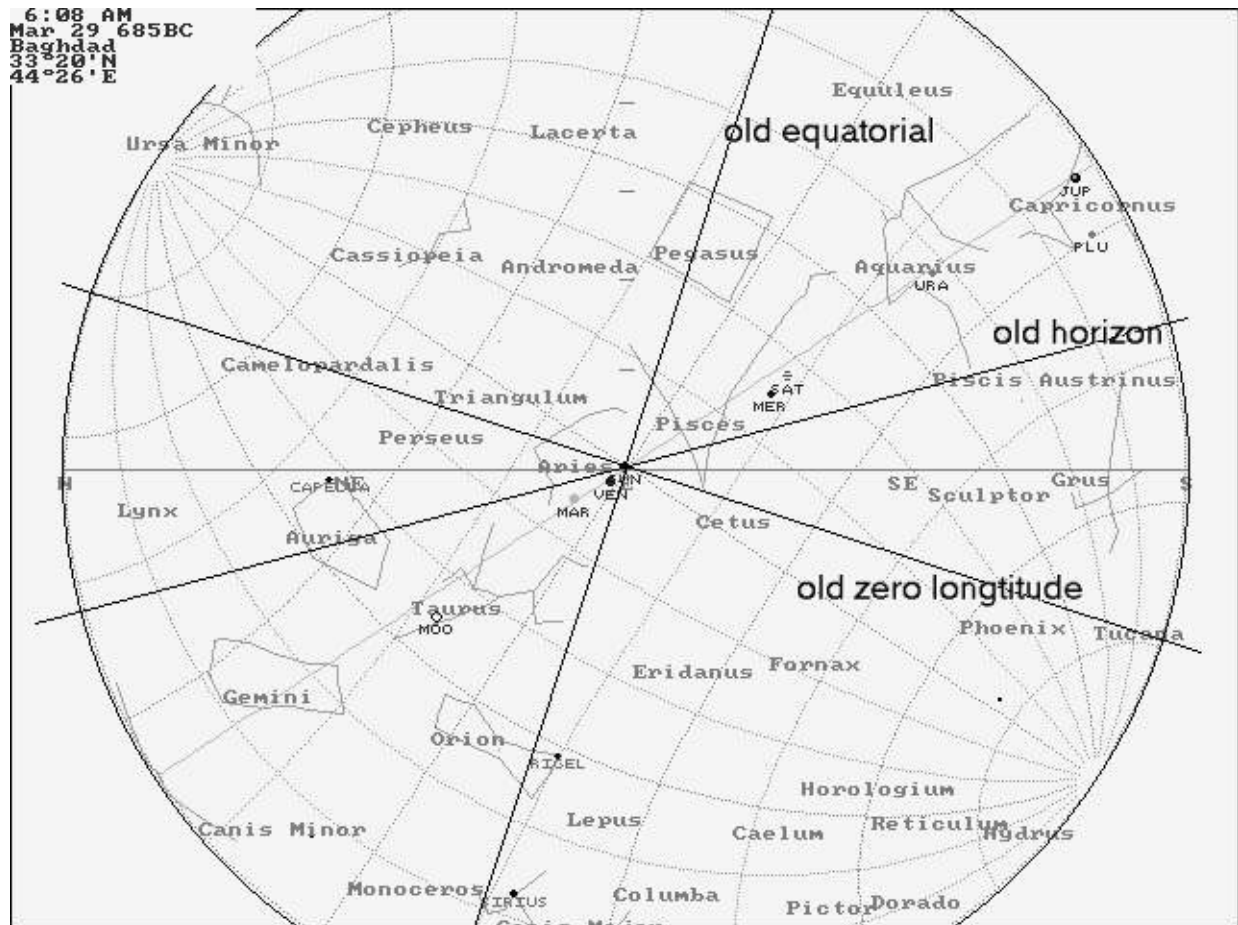

This is the same displacement we see for the record of the Sun and Moon on June 15th. They are not in Cancer, but somewhat west of Cancer. Likewise Venus and Mercury are not exactly riding the back of a lion, but just west of Leo.

Then "Uranus," who is Jupiter of the family of Uranus, entered the fray, and throws both the Sun and Venus to Earth, that is, below the horizon. It is possible that Saturn is meant by "Uranus." Saturn is the son of Uranus. (The planet we have named "Uranus" since AD 1781 has nothing to do with the identification of planets in antiquity.)

The oracle (which is a vision of future events) claims that then the world will be set on fire, and the stars will disappear:

*"Then swiftly smitten down upon the baths
Of Ocean they set all the earth on fire;
And the high heaven remained without a star."*

We should be able to imagine what this looked like. The "baths of Ocean" is the zodiac or the region below the zodiac, but also might be the actual ocean, the Mediterranean. In most of the retellings of late antiquity, which all apparently take some 5th century BC play or tale as their source, possibly a lost play of Aeschylus, *The Heliades* ("Daughters of Helios"), Phaethon falls into the river Eridanus, which was identified as a constellation at an earlier time. [\[note 8\]](#)

[Image: East hemisphere of the sky, after 685 BC. From SkyGlobe 3.6.]

But in the later retellings Eridanus is simply localized in the west, in the land of the Celts, also often identified as the Po in Northern Italy (which was under Celtic occupation in the early days of Rome), or in Spain, another well-known Celtic region. A location in the west would have been correct, for the splashdown of the plasmoid of Jupiter would have happened after the Sun had set north of directly west, and would have brilliantly lit up the western skies for hours. Setting the world aflame and the disappearance of the stars is also correct, for the stars would have disappeared in the light of the nine-hour-long flash.

New Locations of the Stars

The intervening lines of the text deal with the new locations in the sky of the zodiacal constellations plus Orion, Draco, and the star Sirius. All the changes relate to the location of the ecliptic, the equatorial, and the horizon. The change in the starting point of the year was probably noted by the next year, 684 BC. But the change in the location of the polar axis was noticed immediately. The change would move some constellations up in the sky and would move others down. Two lines indicate this clearly:

"Draco disavowed his zone."

Draco, a circumpolar constellation, before 685 BC chased the tail of the Big Bear, Ursa Major, where the polar axis was located. When Ursa Major suddenly dropped "down" by 6.5 degrees, Draco, the most noticeable northern constellation, started to rotate about another space away from Ursa Major. Today it revolves around the star Polaris of Ursa Minor.

"from the Sun's flame Sirius slipped away"

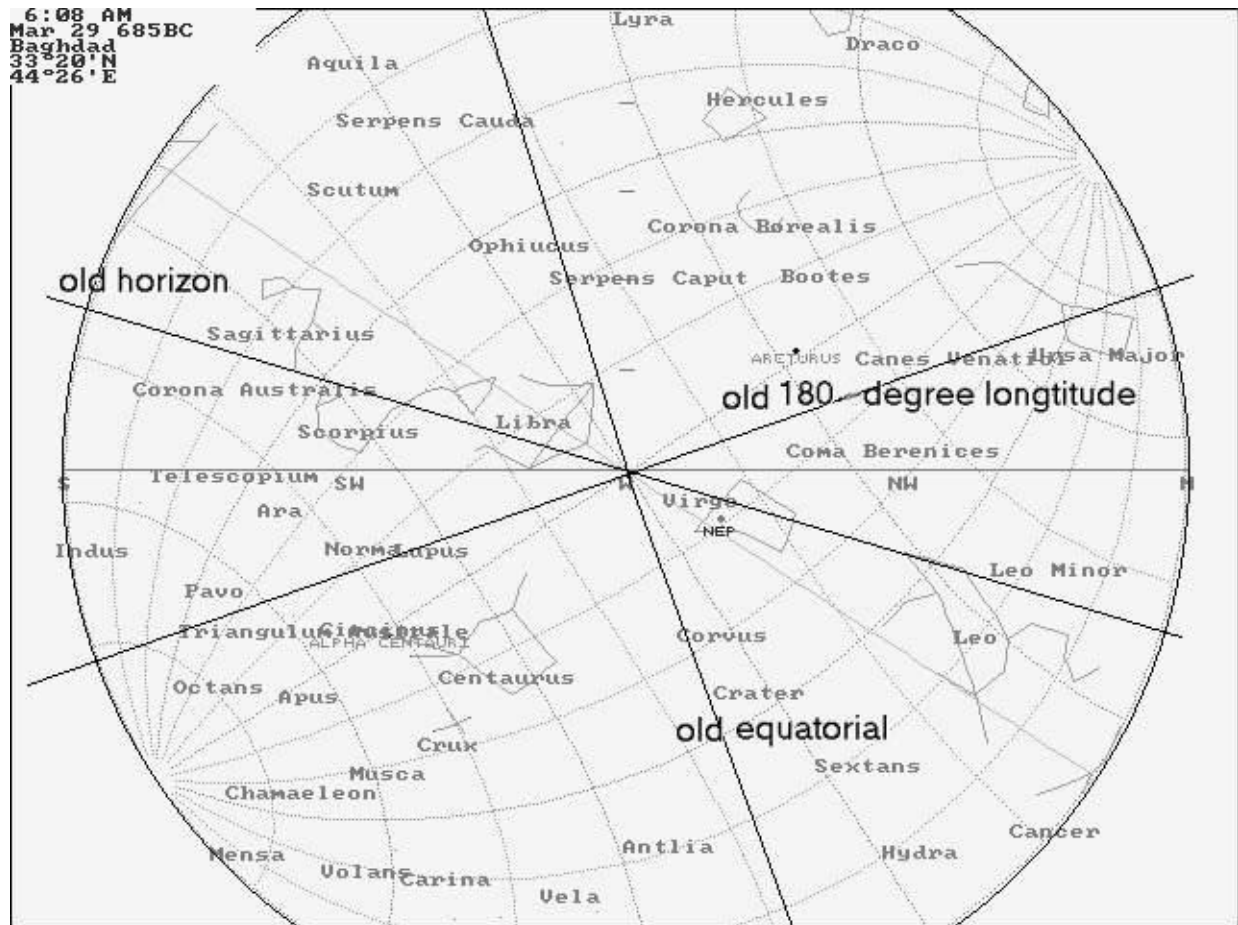

As I noted in prior text, Sirius was formerly located very near the equatorial -- about 2 to 3 degrees below. (See Sirius at the bottom of the diagram above, almost directly on the old equatorial.) After the change Sirius had dropped some 18 degrees below the equatorial. The "slipping away" of Sirius also reveals that it failed to rise or show in June, as it had in the past, and rose instead a month later. Sirius had been the primary star used as a celestial marker for ocean navigation, rising and setting almost directly east and west.

*"Orion would no more
Abide his yoke"*

In November Orion is seen in the southern sky with Gemini and Taurus above his shoulders. This did not change after the polar axis shifted, except in the spacing of these three constellations as seen in the sky. The equatorial cut across the bottom stars of Orion before 685 BC and through the top stars after. (Today it passes through the center of Orion.) The "yoke" might refer to the belt of three stars.

*"the lot of Gemini
Did Virgo change in Aries;"*

"Virgo" here is "the virgin," an almost universal appellation for Venus in the Eastern Mediterranean region ("the maid"), who changed Gemini's lot by being in Aries. Gemini's lot would have been to be suppressed further below the horizon at the start of the year. I am either reading this incorrectly or it is recorded incorrectly, for it would suggest a time of the year when Venus appeared in Aries. Otherwise by "Virgo" the constellation is meant.

[Image: West hemisphere of the sky, after 685 BC. From SkyGlobe 3.6.]

The translation may, in this case, have reversed two constellation names, for at the concluding date, July 25 (August 1, Julian), Venus ("the virgin") was in Gemini, which implies that it was the lot of Aries that had changed. Aries's lot, of course, was to be the opening constellation at the start of the year -- at the new equinox -- noticed the following year when the Sun rose at the midpoint of Aries, rather than at the start of Taurus.

I should point out also that it was this phrase which led Kugler to the conclusion that the *Sibylline Star Wars* only described the path of the Sun starting in September, when the Sun is in the constellation Virgo (in 100 BC). I read this differently.

"no more shone
The Pleiades;"

The above line is another clear reference to the change in the location of the equinox. With Taurus below the horizon at the start of the year, the Pleiades, located at one of the horns of Taurus, would no longer announce the start of spring and the start of a new year.

All the constellations moved, not with respect to each other, but with respect to the equatorial and the horizon of the Earth. The equatorial is a circle in the sky connecting east and west

which is tilted at an angle above the south horizon equal to the complement of the latitude where it is observed. Thus the stars moved with respect to the horizon and the top of the sky.

*"Down into Leo's girdle Pisces went.
Cancer remained not, for he feared Orion;
Scorpio down on dire Leo backwards moved."*

Scorpio did not move backwards. But any review of the zodiac at a later time might note discrepancies which should not be there if the constellations had been designed by God. Scorpio is placed below the ecliptic, as is Sagittarius, and Leo is off the ecliptic in the opposite direction. Both of these locations remained the same before and after. The ecliptic did not move with respect to the constellations.

Cancer (as well as another half-dozen constellations) moved up in the sky, while others sank. "Leo's girdle" is the belt of the equatorial. It should be remembered that both the ecliptic and the equatorial were still strewn with dust in 685 BC. The "zodiacal light" of the ecliptic lasted to AD 1840. The dust of the last ring of the equatorial (the remnant of the Absu, the Uroboros) probably lasted to AD 400 or 600.

Conclusions About Dates

As I have pointed out elsewhere, these were not minor changes. It is for this reason, plus the lighting up of the day sky by the nova event of Venus and Mercury, plus the enormous flash on the 25th of July, that the event was understood as a war among the stars. When it was over every constellation had moved -- to where it should not be.

After blazing up in 685 BC, and then failing to disappear in front of the Sun in the west (in late December), Venus showed again as the Morning Star in early January of the next year. So say the *Venus Tablets of Ammizaduga*, or, as Mesoamerica has it, "Quetzalcoatl rose in the east as the Morning Star."

I have no question at this point that the shift of the polar axis and the change in the equinox happened, and happened suddenly, especially when combined with such comments from other sources.

I will maintain that the main "event" concluded on July 25th of 685 BC, with a plasmoid strike from Jupiter. I have detailed the derivation of this date in earlier chapters. The Guatemalan *Popol Vuh* suggests that the ecliptic remained obscured for four days after Hunahpu and Xbalanque jumped into the oven of the Xibalbans. Ovid suggests that the Sun did not show for a day (but then, Ovid places all 40 days in one day).

The descriptions of the phenomenon as a "throne," as a "horse without hips," or, as in Ezekiel's vision, of "brass glowing like fire in a furnace" and a "fire with encircling

radiance," all speak to a display with much shorter plasma outpourings ("flames"). This would be the condition of Mercury as it reached inferior conjunction with Earth, and its plasma stream was directed towards Earth, and therefore visually foreshortened.

The Chilam Balam

An accurate Mesoamerican source, the Maya *Chilam Balam* books, reads that the Sun "moved from its place for three months," in Katun 3-Ahau (688 to 668 BC) and would return after "three heaps of years," or at least by the end of Katun 3-Ahau, that is, before the end of a twenty-year Katun period.

As I have pointed out, all five time spans recorded in Book 10 of the *Chilam Balam* use inclusive counting. So the "three months" represent a span of two Mesoamerican Uinal months of 20 days, a total of 40 days. From the *Popol Vuh* it is obvious that Venus and Mercury need to be close together in the sky (they hold hands) at the start of the nova event. June 15 (Gregorian) qualifies, and is, in fact, 40 days before July 25th.

The second remark in the *Chilam Balam* (about three heaps of years) reads as follows:

"After three years [three heaps of years] it will come back into place in Katun 3-Ahau. Then another Katun will be set (in its place)."

We do not really know what "heaps of years" are, but I would guess that they are groups of five, as used on Maya counting boards, and further, that these are Tzolkin cycles of 260 days, and therefore we should count an interval of 14 (three times 5 less one), not 15 (three times five).

The "place of the Sun" would be measured by its setting location along the horizon and matched against calendar records of when and where this was expected. After the disturbance of the orbit of Earth in 685 BC, and after quiescence had returned, the Sun would rise and set again where expected, that is, on the proper date of our calendar, but not on the same date on the Mesoamerican Tzolkin calendar. But it turns out that 14 cycles of 260 days are exactly correct in "returning" the zenithal passage of the Sun to the same Tzolkin calendar day-name for a latitude of 17 degrees north. What was important for Mesoamerica in this instance was the fact that the Sun obeyed the Tzolkin.

Of course, the Sun did not return to its proper horizon setting location on the same dates. Normally with the Mesoamerican calendar, the same Tzolkin day-name and day-number corresponding to the same Gregorian calendar date happen only after 20 Tzolkin rotations. Fourteen rotations will be 12 days short. It did return to the same horizon locations for zenithal passage over the sites in Mesoamerica, from which we receive the fiction perpetrated by the Olmecs that the Sun had returned to its proper place. I discuss this in the chapter "Olmec Alignments."

Nonnos's *Dionysiaca*

The writers mentioned above who have commented on Kugler's work have gone on at some length about the fact that Kugler's book does not reach the conclusion it might have originally intended to have. The book is, after all, about Phaethon. Kugler does not place the appearance of Phaethon in 100 BC, but only suggests by the accuracy of the description that we should not neglect the "legends" from circa 1500 BC, or what is thought to be 1500 BC -- that is, the Exodus of 1492 BC.

In fact Kugler supplies a series of sources for the dates of the fall of Phaethon which solidly place the event at the time of Moses. I have no disagreement with this as long as it is recognized that the events at the time of Moses (that is, in 1492 BC) are described by the Typhon legends, not the Phaethon legend. But what we also see, of course, is the Typhon legend reworked to fit the later event of 685 BC. The Star Wars prophecy is not the only instance. Another instance used by Kugler is the *Dionysiaca*, written another 300 years later, in circa AD 450, under the name of Nonnos.

This is a poem detailing the complete adventures of the God Dionysus, composed in the antique style of Homer and Hesiod (as was the style in Greek literature). Book 38 has a description of the Phaethon legend, which again describes changes in the sky overhead, with claims of all the constellations moving to different locations. The details of the description are almost incomprehensible in terms of an exact reading, unlike the *Sibylline Book*, with the zodiacal animals growling and clawing at each other, but the concluding lines are of interest. It reads:

"No longer did the stars in the Bear, moving in a circle fastened around his hips, dance up high near the northerly pole, but moved to the southwest and wet their dry feet in the Lake of Hesperia at the unaccustomed Oceanos."

Hesperia is a mostly fictitious ocean in the sky, probably based on the Absu, and adjacent to the river Oceanos, which is probably the last red ring below the equatorial. These particulars are mostly a poetic formulation. But more important, here we have the Phaethon legend tied to the change of the dome of the stars, like in the *Sibylline Book*. This is preceded, earlier in the description, with:

"Even the axis, which turns in the centre, began to totter through the whirling ether."

And:

"But winged Virgo sped past Arcturus, approached the Axis and collided with the Wain. The Morning Star sent erring rays to the western rim, and was even then pushing away the Evening Star, which stood opposite."

This actually describes the concluding dates of the event. Venus (Virgo) stood in the sky

below Arcturus, maybe 17 degrees further west, while, with the Sun set already, Mercury (now the Morning Star west of the Sun) was already below the horizon and indeed stood opposite Venus (now identified as the Evening Star, for it followed the setting Sun).

Two Meteors

Kugler sees in the *Sibylline Star Wars* a description of the arrival of two meteors, but takes this information no further, perhaps suggesting that these phenomena would have disappeared in a few days. Malcolm Lowery wrote:

"Kugler recognizes in lines 512, 513 and 515 a description of the arrival of 'two enormous meteors of the apparent size and form of the sun and the moon . . . with their characteristic accompanying features', but is happy to leave them out of the further action, accepting them, presumably, as no more than the excuse the ancients needed to write a poem about the events following."

I would suggest that the blazing Venus seen next to the blazing Mercury would be sufficient to explain "two enormous meteors," especially if they are suggested to be of the same size as the Sun and the Moon (the Sun and Moon are the same apparent size). There are Chinese sources in antiquity which recall that at one time "two Suns" were seen battling in the sky.

Dating the Denderah Zodiac Ceiling

(May 2007) The temple of Hathor at Denderah in southern Egypt contains a very unusual circular zodiac ceiling panel in one of the auxiliary buildings. The temple was rebuilt under Roman rule sometime in the first century. The zodiac panel may have been started under some of the Ptolemies, perhaps a hundred years earlier.

[Image: Denderah zodiac ceiling; Approximately 8 feet (2.5 meters) across. Collection of Louvre Museum.]

Since its discovery in 1799, various researchers have attempted to determine what date might be depicted by this star chart. The zodiac of the Denderah ceiling is not very accurate, however, as others have noted. But accuracy was never an issue in Egyptian depictions of the stars. It was all about religious symbolism. The iconography of the zodiac is solidly Ptolemaic Greek, however. It politically gives recognition to earlier Egyptian astronomy with an outer border of decans. Decans are a series of stars that rise every hour at night, marking time. There are 36 for use throughout the year, one every ten degrees.

I am using a portion of the locations of planets as determined by Julie Gillentine in "The Zodiac of Dendera" (*Atlantis Rising*, 2001), and Joanne Conman in "The Round zodiac Ceiling of the Temple of Hathor at Denderah" (*The Secret Chambers of the Sanctuary of Thoth*, 2002, on line).

Gillentine made the selection without recourse to the identification of certain figures as planets, so that, for example, I disagree with her selection of Jupiter and Saturn. I selected the duck between Sagittarius and Capricorn as Jupiter. The duck is the Sun, and the Sun had been Jupiter.

Conman identifies a number of figures with Gods and Goddesses of southern Egyptian

nomes, which I do not think is called for. This is a notion first brought forward in the 19th century. This is just unlikely. There are many more nomes than there are figures in the ceiling zodiac. And it certainly also does not apply to the figures of the decans, for these were well established, and had nothing to do with local temple concerns.

[Image: Figures with Was scepters at Denderah, incorrectly attributed to planets. Decans not shown. Original after Conman.]

The time depicted by the zodiac chart would be about midnight, with Jupiter almost directly south and the full moon in the south-southwest. Sirius (the ox in the boat) is shown directly north, but this would be below the Earth and only rotate into the daytime as the skies turned.

From the ceiling zodiac the locations of planets can be read as presented in the text below. Some of the constellations have been turned, shrunk, or dislocated, however. The example which everyone will recognize at once is that Aries is reversed, facing Taurus, and looking over his shoulder toward the west. Some of the planets are erroneously or haphazardly placed. Mars, for example, seems to be placed early in Gemini, away from where it ought to be in Cancer. But Sirius is also below Cancer, which cannot be, because Sirius and the constellations are immovable stars. Sirius belongs below Gemini.

[Image: Figures as planets and zodiac signs at Denderah; Decans not shown. Original after Conman.]

Finding the year and date for this configuration of planets is thus problematic, but it can be done. If Saturn is in Pisces, there are only two or three years which need to be inspected out of every thirty years to find Jupiter in Capricorn. In all cases the month of July or August has to be selected, since the Sun must be in Leo. Mercury will be there also, and Venus should be close by. The appropriate year can be located from the requirement of having Mars in Gemini or between Gemini and Cancer.

There is a question as to which figures constitute the planets. There is a set of standing figures which each hold a *Was* scepter, which normally indicates their status as Gods. (One remains unidentified in Scorpio, plus Orion is likewise equipped with a *Was* scepter.) These are held to be the planets placed in their governing house, that is, each is located in a zodiac sign of importance to that particular planet. The concept that every zodiac sign has a "ruling" planet which has particular potential in those locations has come down to modern times in astrology, and is called the "exaltation" of the planets. The genesis of this is a complete mystery. It was already established in Babylonian times.

The location of the exaltation of the planets does not constitute a plan for a date for the

zodiac, since Mercury (in particular) is much too far removed from the (assumed) location of the Sun in Aries. Mercury is located three or four zodiac signs away in this schema -- the Sun is not in Aries. I wanted to point this out.

If we are to look for another indication of a date, we have to look at a more correct set of symbols which encode planet names and locations. These are listed below.

- "Venus in Virgo" -- Venus (Isis) with Horus on her hand.
- "Sun and Mercury in Leo" -- Mercury to the west, shown as an archer, the Sun holding two jars, and with a plumed head dress.
- "Mars in Cancer or Gemini" -- This is the crowned falcon on the papyrus plant. He is shown below Gemini, but should properly be below the adjacent Cancer.
- "Moon in Pisces" -- The Moon is the baboon above the Eye of Ra.
- "Saturn in Pisces" -- the figure of the *Eye of Ra*.
- "Jupiter in Capricorn" -- The duck ("Ra") between Sagittarius and Capricorn -- since the duck is the sun, which was Jupiter for thousands of years as the Sun of the night.

It is this last, the duck as Ra and Ra as Jupiter, which has consistently sabotaged all efforts at determining a date, or even a coherent listing of planets, for everyone holds Ra to be the Sun, whereas for 3000 years Jupiter was identified as Ra. And all too many researchers have thought that the duck in this zodiac is just decorative, like the corresponding *Eye of Ra* in Pisces. The *Eye of Ra* is not decorative, it is Saturn.

Now to determine a date. In the time span of the half millennium preceding the first century BC, when the zodiac ceiling was installed, only three events stand out as universally significant. The first was the lengthening of the year in 747 BC. The second was the Earth shock by Mercury and the burning tower of Babel in 686 BC. Both of these were spring events, with the Sun in Aries.

The third event was the delivery of the plasmoid of Jupiter at the Sun on July 25, 685 BC. I only reached a conclusion about this date when I realized that the baboon in Pisces was a well-established symbol for Thoth, but by Roman times Thoth had migrated its planetary association from Mercury to the Moon. Mercury had all but disappeared from the skies 460 years before the Roman rebuilding of the temple, and the assignment of the messenger of the Gods had passed to the Moon. The Moon should be in Sagittarius on July 25th. It would be in Capricorn two days later, in Aquarius in four days -- roughly two days of displacement for every zodiacal house. The Moon reached Pisces in six days. Here it is the baboon above the *Eye of Ra*.

This extension of six days after the actual delivery of the plasmoid (on July 25) reflects how soon the skies cleared of plasma at the Sun, and accounts for further events, including the delivery of subsequent smaller plasmoids.

The *Popol Vuh* suggests that the ecliptic remained obscured for four days. About the

blowgunner twins, Hunahpu and Xbalanque, who had just been burned up and their ground-up bones cast in the river, the *Popol Vuh* reads:

"And on the fifth day [after] they reappeared. They were seen in the water by the people. The two of them looked like catfish when their faces were seen by Xibalba."

The blowgunner twins of the *Popol Vuh* were seen as catfish. You will find later in the Chapter "The *Popol Vuh*" my comments:

"Catfish were seen, but these are more likely additional minor plasmoid bolts from Jupiter. Since these would have traveled in the ecliptic, they might easily be mistaken for Venus and Mercury, especially when it was unclear where these planets were. The catfish were seen while the day and night skies blazed with the reaction of the Sun to the initial plasmoid strike from Jupiter."

Selecting the baboon as the symbol of the Moon, places the Moon in Pisces. That would bring the close of the event to July 30, Gregorian. The close of the event was the beginning of a new creation. There were no further interferences by any planets after this date. The following spring showed all seven planets in a line in the sky -- the start of a Great Year.

Endnotes

Note 1 --

A number of numismatic sites with an interest in astronomy have suggested that the seven stars might represent a conjunction of all the planets in the sky. It is also suggested that the seven stars represent either Ursa Major or the Pleiades. And, in fact, the earliest coin of this nature dates from AD 76 and is clearly marked TRIO, short for Septentriones, a name for the seven stars of the Wain (Ursa Major) and generally meaning "north."

[\[return to text\]](#)

Note 2 --

Some conjunctions only last a day, some last a week. The location of the Moon is not hard and fast, since it moves 12 degrees per day.

Oct 5, 7 BC, Sat, Jup, Moon, Mar, Ven, Mer, Sun (setting)
Jul 5, 6 BC, Sun (rising) Mar, Ven, Mer, Jup, Sat, Moon
Apr 6, 4 BC, Moon, Jup, Mar, Mer, Sat, Ven, Sun (setting)
Mar 7, 2 BC, Jup, Sat, Mar, Ven, Mer, Moon, Sun (setting)
Oct 27, AD 1, Sun (rising), Jup, Mar, Ven, Mer, Moon, Sat

[\[return to text\]](#)

Note 3 --

To get a glimpse at how easy it is to calculate planet positions in the past or future, take a look at how Patten and Windsor make these calculations in *The Mars-Earth Wars* (1996), reaching back 2300 years. Patten and Windsor use data listed to many decimal places, but this would not be much different from what was available in antiquity, which had already accumulated 600 years of data by AD 200.

[\[return to text\]](#)

Note 4 --

The complete Sibylline text follows. I have broken it up into sections to clearly indicate the composition. Line numbers are in brackets.

The opening lines:

*[689]"I saw the threatening of the shining Sun
Among the stars, and in the lightning flash
[690] The dire wrath of the Moon;"*

The battle:

*"the stars travailed
With battle; and God gave them up to light.
For long fire-flames rebelled against the Sun;
Lucifer treading upon Leo's back
Began the fight; [695] and the Moon's double horn
Changed its shape;"*

The lasting change:

*"Capricorn smote Taurus's neck;
And Taurus took away from Capricorn
Returning day.*

The changes in the sky:

*"Orion would no more
Abide his yoke; the lot of Gemini
Did Virgo change in Aries; [700] no more shone
The Pleiads; Draco disavowed his zone;*

*Down into Leo's girdle Pisces went.
Cancer remained not, for he feared Orion;
Scorpio down on dire Leo backwards moved;
And from the Sun's flame Sirius slipped away;"*

The closing passage:

*[705] "And the strength of the mighty Shining One
Aquarius kindled. Uranus himself
Was roused, until he shook the warring ones;
And being incensed he hurled them down on earth.
Then swiftly smitten down upon the baths
[710] Of Ocean they set all the earth on fire;
And the high heaven remained without a star."*

[\[return to text\]](#)

Note 5 --

The spikes in four directions from the three planets would likely result in the later claim of the crucifixion of Christ and two robbers, or of Mithra. The down directed spikes were crossed at about half their height by the remaining red ring in the sky, resulting in a blood-red swatch on each and looking like the genital mutilation performed with crucifixions. See, for example, *The World's Sixteen Crucified Saviors* (1875) by Kersey Graves. Four of Graves's saviours are dated to about 1200 BC, one in 1700 BC, and all the rest in the era of 800 BC to 500 BC.

[\[return to text\]](#)

Note 6 --

I have made this statement before, that Venus would have lost its tail and large coma at this time, but this is not at all certain. Only by the time of the writings of Aristotle (384 BC to 322 BC) do we see a definite attempt to separate planets from meteors and more ephemeral phenomena (which last are classified by him as "weather"-- meteorology). Stecchini writes, "It is significant that, after having described the general topic of meteorology, Aristotle begins the treatment of it by refuting those who say that 'the comet is one of the planets'." The "comet" here is Venus.

[\[return to text\]](#)

Note 7 --

In fact, I have not been able to pinpoint a closing date. The document clearly records all of

the travels of Venus between an unexpected blazing in June and (perhaps) the subsequent easterly reappearance -- except that there was no westerly disappearance of Venus. On this occasion, as an ephemeris will show, Venus rode about 8 degrees above the Sun as it was setting in the west, and reappeared the next day in the east at sunrise.

This would explain the missing data at the close of year eight of *The Tablets of Ammizaduga*. I would suggest furthermore that Venus may have changed its orbit with the relocation of Mercury in the previous year. That, in turn, explains perhaps the fact that Venus set a month late, as noted by Rose and Vaughan, and which remained inexplicable to them. Normalization of data does not tell one anything about orbits.

The closing date indicated with the Denderah Zodiac ceiling is five days later than August 25. See further text below.

[\[return to text\]](#)

Note 8 --

The constellation Eridanus is identified as a series of stars hanging from the left foot (Rigel) of the constellation Orion and reaching the horizon -- like a river -- even with Orion high in the sky. In July of 685 BC Orion and Eridanus are both west of the Sun and below the horizon at nightfall, but they rise in the east 4 hours before sunrise. Eridanus is located well below the ecliptic and the equatorial. The star Rigel is at the same relative altitude (44.5 degrees at culmination for Cairo in 685 BC) as Sirius (42.1 degrees). The start of Eridanus, which dips down (toward the southern horizon), would thus be located behind the last red ring of the original Absu which also gave Sirius its red color. The blood in this river -- backlighted perhaps by the flash at the Sun, below the horizon -- would be convincing evidence of the death of Phaethon.

Recovering the Lost World, A Saturnian Cosmology -- Jno Cook

Chapter 28: Language and Causality.

\$Revision: 42.50 \$ (lang.php)

Contents of this chapter: [\[Consciousness\]](#) [\[Becoming Human\]](#) [\[Language Development\]](#) [\[Boat People\]](#) [\[Languages and Texts\]](#) [\[Subjective Consciousness\]](#) [\[Advantages\]](#) [\[Disadvantages\]](#) [\[Children\]](#) [\[Endnotes\]](#)

Primates learn from their peers, not from adults.
-- Sherwood Washburn, [\[note 1\]](#)

Consciousness

And now for something entirely different: Let me introduce *subjective consciousness* at this point, and language and texts as a secondary topic. The reason for presenting this material is two-fold. First, I need to point out that an understanding of events in the remote past is never modulated by abstract metaphors, something we today do with great fluency. The events of the distant past are facts, they never "stood" for something other, excepting perhaps in the use of similes. Secondly, I need to point out how grammar effects the understanding of the world for different people, how it completely and radically changes concepts which we take for granted. This is particularly relevant to an understanding of the following chapters which deal with Mesoamerica.

Subjective consciousness is not biological. It is a learned faculty, like language, and is thus dependent on contacts with other people and includes within its structure the ability to promulgate its use to others by purposeful example. To become *subjectively conscious* means to learn how to *teach subjective consciousness* to others, and thus keep *subjective consciousness* alive. This is no small task, yet we constantly perform the task of teaching through our dialogues with others and we do it automatically.

Even the most ardent micro-evolutionist will have to admit that language and speech were probably not available to humans before about 10,000 BC. (see John Halloran at www.sumerian.org/) And much, much later came consciousness as we experience it today. Of course, our experience of consciousness is so entwined with our identity, and seems so overwhelmingly innate, that anything suggesting differing conditions, like the notion that our experience of extended consciousness -- *subjective consciousness* -- is not biological, but is

cultural, will bring most people's reflection on this topic to a complete halt. It comes as an immense shock to realize that *subjective consciousness* is only a very recent development.

We are here not talking about consciousness, self-consciousness, or self-awareness. These are qualities possessed by all animals. It allows them to identify themselves, allows them to associate past experiences with their peers and mates, allows knowledge of the thousands of details of a wide-ranging geography, and allows the incorporation of learned experiences. We do all that too, and mostly without thinking about it.

And we point fingers, and understand others when they point. As Malcolm Gladwell notes in *Blink* (2005), "... interpreting a pointing gesture requires, if you think about it, that you instantaneously inhabit the mind of the pointer." Most animals don't get it. Animals do not seem to do well with questions either, which represents a similar displacement into the mind of another person. [\[note 2\]](#)

I will describe *subjective consciousness* as distinct from *consciousness* further below. At this juncture it might be more instructive to list some examples of people who, for any number of reasons, have remained *pre-subjectively conscious*. These include people who are very accomplished, for example, musically, but have never composed anything new or even improvised, people who can draw or paint with mastery but only derivatively and have never produced a new image. Or the person who keeps asking you and others for advice on some question, yet never acts on it. Here there is a failure of imagination, or as others have suggested, a failure of judgment, although I would hold that we are dealing with both the inability to imagine and to make judgments based on what was imagined. This is a poor integration of functions which the left-brain is capable of with the remainder of mental activities which we would call "thinking."

Of course it is possible to get through life without ever accessing or exploring the analogical vistas of the imagination, just as it is possible to converse without ever using metaphors. Such conversation, or such thinking, can certainly present the complexities of relationships, the gripping realities of emotions, and the humor of situations. And we can still fill a dialog with lies and falsehoods, just as we can deliver biting sarcasm. What can't be done easily is to present or suggest a situation to the recipient of our dialog which is composed, not of reality, but of a what-if situation -- an analogical reality, offered to the hearer for his personal exploration.

The lack of metaphorical thinking in remote antiquity is critical to understanding what we are told by our forebears. The languages in which the first observations of the heavens were rendered were specific and concrete -- as Jaynes suggests -- "end to end." These people were not creating symbols or dealing in mystical religious philosophies; what we are told of was exactly what was seen and experienced.

This is, in fact, what Jaynes proposes, that metaphorical thinking dates only from after 1000 BC. Jaynes demonstrates this through examples and details from the earliest historical texts

and through an analysis of cult objects of Mesopotamia and Egypt. Of course, nothing is proven, for nothing can be proven about the mentality of an era we did not participate in. But enough striking examples are brought forward to suggest that his hypothesis might very well be correct. I should point out that Jaynes was completely unaware of any of the catastrophism developed in this text.

What is more significant is that Jaynes's concept of *subjective consciousness* is based on a working model of the mind which has very large predictive value. This is also why there has been no follow-up to Jaynes's model. Besides stepping away from academic mainstream psychology in writing *The Origin of Consciousness in the Breakdown of the Bicameral Mind* (1976), Jaynes's model, which locates consciousness exclusively in the left hemisphere of the brain and delegates volition to the right half, in effect closed the door to further research, despite the fact that vast behavioral areas remained to be explored, for the basis of the model was largely philosophical, it was not clinical. But it works!

Current stock psychological research, as with neurological research, is based entirely on stringing together data from endless clinical studies. It also tends to be very reductive, equating conclusions from clinical data to elements of computer models and electrical circuitry, despite the fact that the interrupt-based methods of computer processing are not equivalent to the simultaneous capabilities of the brain -- the only true multi-processing system.

You will also see a reductiveness to named parts of the brain as if "firing order" and "activity" are causally meaningful. They are not. The dependence of the limits of clinical data is equivalent to the stalemate reached in the study of language some decades ago -- a reduction of words to sounds and phonemes without a single notion of how to jump from there to syntax.

But despite the turn by professionals to the academic minutia of clinical studies, the broad concepts of separate left and right brain are alive in popular culture. Separate qualities are often ascribed to the two hemispheres, which are, however, generally totally wrong. To say that the left hemisphere is capable of speech, for example, is completely correct, for we are aware of this faculty. To say that the left hemisphere is logical and the right hemisphere is intuitive is completely bogus. Nothing which may be accomplished by the right hemisphere is accessible to consciousness, so that nothing can be said about the workings of the right hemisphere except by inference. And the inferences come from feelings, from reminders and admonitions (often inappropriate) which spring to mind, and from images that impose themselves on consciousness. [\[note 3\]](#)

Malcolm Gladwell, 2005

A book by Malcolm Gladwell, *Blink* (2005), relates the ephemeral nature of the communication of the silent right brain with the conscious left. The book opens with attempts

of the Getty Museum in California to verify the authenticity of a Greek statue, a kouros, dating from 500 BC which had been offered for sale to the Getty. The investigation, which included stylistic considerations, the provenance of prior ownership, the source of the material, and the evidence of 2000 years of aging, took 14 months.

In 1986, at the completion of the investigation, the kouros was viewed by a number of experts in ancient Greek sculpture. Frederico Zeri (on the Getty's board), stared at the kouros's fingernails when unveiled -- they looked wrong. Evelyn Harrison (an independent curator) felt something was amiss and recommended against purchase. Thomas Hoving (Metropolitan Museum of Art, NY) recalled that the word that jumped into his mind at the first sight of the kouros was, "fresh," hardly appropriate for a statue reputed to be 2500 years old. Hoving also recommended against purchase.

The Getty shipped the kouros to Greece and called a conference of experts. Here are additional responses: George Despinis (Acropolis Museum, Athens), to quote Gladwell, "took one look at the kouros and blanched." Georgios Dontas (Archaeological Society, Athens), saw the statue and felt cold, he felt, he said, "as though there was glass between me and the work." Angelos Delivorrias (Benaki Museum, Athens) felt a wave of "intuitive repulsion" at the first sight of the sculpture.

The experts were eventually vindicated; the kouros was indeed a fake. But now look at the broad base of opinions of the experts: All of them made up their mind within one or two seconds after first seeing the kouros. Not one of them could articulate the reasons for their opinion or "revulsion." Note that the feeling of incorrectness seemed to be universal, but also note the words which entered their minds, and the image of the glass. These were all articulate people, yet they were stumped to explain their "feelings."

What is most amazing is that the inarticulate part of the minds of these six curators managed to come to identical conclusions in under two seconds each, when the Getty had managed to get the wrong answer after 14 months of expert investigations. The speed is phenomenal, but the inarticulateness and terseness of communication between the silent right brain and the conscious left mind is a definite drawback.

Gladwell, following current theories, writes, *"The part of our brain that leaps to conclusions like this is called the adaptive unconscious, and the study of this kind of decision making is one of the most important new fields in psychology."*

Daniel Goleman, 2006

As a second example of the reduction of Jaynes's left rear and right rear hemispheres to smaller constituent parts of the brain, consider Daniel Goleman's book *Social Intelligence* (2006). Goleman uses both sociological and neurological clinical sources in an attempt to define social interactions as dependent on pattern recognition. Here the high-speed

recognition, which he calls the "low road," at least has a clear method of communicating its findings to the conscious left brain. On recognizing an emotion in others, the observer will duplicate this in his own body. Goleman calls it "emotional contagion."

"Emotional contagion exemplifies what can be called the brain's 'low road' at work. The low road is circuitry that operates beneath our awareness, automatically and effortlessly, with immense speed. Most of what we do seems to be piloted by massive neural networks operating via the low road -- particularly in our emotional life."

The "high road," writes Goleman:

"... in contrast runs through neural systems that work more methodically and step by step, with deliberate effort. We are aware of the high road, and it gives us at least some control over our inner life, which the low road denies us."

The "immense speed" of the low road, however, is relative. The brain can operate at an immense speed with familiar material. All of us have been looking at faces and associating facial expressions with emotions since we were a month old. The same operation "beneath our awareness" takes hold in typing or playing a musical instrument. But ask yourself a difficult question, and it may take weeks or months before an answer "pops into your mind" based on all the information you had already gathered. It is the "unaware" right brain which will have reviewed all the relevant data that you have consciously accumulated, perhaps over a lifetime.

Goleman lists (after Matthew Lieberman) some brain areas involved in processes which escape conscious awareness, as the amygdala, basal ganglia, lateral temporal cortex, ventromedial prefrontal cortex, and dorsal anterior cingulate cortex. It is a long list.

I would be more comfortable with Jaynes's model, which posits a fully functional second mind, but one which has almost no control over speech, and whose operation remains completely inaccessible to consciousness. It is equivalent to being inhabited by another psyche, one who is smart, fast thinking, correct in most situations, but, as has been observed, also willful, impatient, and quickly annoyed.

Michael Gazzaniga, 2008

The third example is a book by Michael Gazzaniga, *Human: The Science behind What Makes Us Unique* (2008), which discusses split-brain (commissureotomized) patients. "Being inhabited" is a concern specifically addressed. Gazzaniga writes:

"Why don't split-brain patients have dual consciousness? Why aren't the two halves of the brain conflicting over which half is in charge? ... Are consciousness and the sense of self actually located in one half of the brain?"

[\[note 4\]](#)

Yes, Jaynes would say. Gazzaniga points out that attention remains fixed on a single spatial location after the brain has been split, as if the two halves were still working together. (Of course this is a fiction. We cannot tell what the right brain is concentrating on.)

He also notes Paul Broca's research (in the late 19th century) which located the center for speech on the verbal left hemisphere, writing, *"A split-brain patient's left hemisphere and language centers have no access to the information that is being fed to the right brain."*

Thirty years earlier, Jaynes wrote about that also. Information can visually be fed separately to each hemisphere by showing separate images to the left and right eye. (There is some loss of information, since the optical nerves of the eyes each split the field of view between the left and right hemispheres.) Under this condition the left and right hemisphere can be asked to respond appropriately to the separate images, and this will be accomplished, for both the left and right brain can understand speech. Since the hands and fingers are almost totally under control of either the right or left brain, the response (like picking an appropriate object) will reflect the decisions of a single hemisphere. This has led Gazzaniga to some conclusions about the separate hemispheres, as follows. (I'll note the right as silent, the left as verbal in the following.)

"Although the [silent] right hemisphere remains superior to the isolated [verbal] left hemisphere for some perceptual and attentional skills, and perhaps also emotions, it is poor at problem solving and many other mental activities"

This badly short-changes the right brain. Goleman, in the previously quoted book, in essence suggested that the silent right brain, or the parts of the brain unavailable to consciousness or introspection, is superb at gauging emotions. Gazzaniga calls it "face recognition." The silent right is also capable of completely logical analysis of data, unlike the left brain which tends to make up even incorrect theories, as the author points out. Gazzaniga writes:

"The [verbal] left hemisphere, on the other hand engages in the human tendency to find order in chaos and persists in forming hypotheses about the sequence of events [in this example] even in the face of evidence that no pattern exists: slot machines, for instance."

The use of the phrase "human tendency" takes us beyond speculation. Now calling the left brain with its apparent inherent need to come up with theories, "the interpreter," Gazzaniga finishes his analysis on a poetic rather than a scientific note:

"How is that two isolated hemispheres give rise to a single consciousness? The [verbal] left-hemisphere interpreter may be the answer. The interpreter is driven to generate explanations and hypotheses regardless of circumstances. The [verbal] left hemisphere of split-brain patients does not hesitate to offer explanations for behaviors that are

generated by the [silent] right hemisphere. In neurologically intact individuals, the interpreter does not hesitate to generate spurious explanations for sympathetic nervous system arousal. In these ways, the [verbal] left-hemisphere interpreter may generate a feeling in all of us that we are integrated and unified."

The waters have been seriously muddied. Jaynes covered all this 30 years earlier, and without recourse to vapid generalizations about consciousness or "human tendencies." Let me start at the beginning, and review what we know.

Becoming Human

As a brief summary: Humans were not always *subjectively conscious*. The nature of *subjective consciousness* was explained in the text. As *subjectively conscious* humans, we are at best 3000 or 4000 years old (2000 to 1000 BC), with a "recorded" pre-history dating back 5000 years (to 3000 BC), and not the slightest significant amount more. All history starts there. There are objects and constructions from before 3000 BC, but they are certainly not "ours" -- not the work of *subjectively conscious* humans. Neither is much of what can be dated to before about 1000 BC. We owe our humanness, like the genesis of Earth's biology, to the "Gods of Creation" -- the planets, and their catastrophic interferences with Earth.

It might have gone another way. *Subjective consciousness* could have never happened. We could still be chipping flints, as *Homo erectus* did for a million years without improving on their one stone tool. Even today there is a great diversity of *subjective consciousness* in the world, a clear indication, I think, that it is not a biological function. Our humanity is something we have to actively work on. We are a gregarious species, a social one, and, as a group, look to others for authentication and authority. That is dangerous because this particular behavior is biological, and represents a fallback position when *subjective consciousness* falters.

We are animals, although we like to think we are different. Our biology is fully integrated into the domain of the mammals. We may have a few features not shared with other mammals, but most are shared. Primarily, like other mammals, we give birth to immature young and need to spend a long time teaching them. All mammals teach their young and that is crucially important to humans. This teaching is overwhelmingly biologically driven, and a subject often completely neglected by anthropologists and archaeologists, for it is "women's work" -- like spinning whorls or all those Venus Figurines. It does not deal with weapons, hunting, or economics. [\[note 5\]](#)

Becoming "human" -- that is, *subjectively conscious* -- was a chance event. There is no biological cause. Language is a prerequisite, but language has the same status -- it also has no biological basis and has to be learned. There are, however, some requisite mechanisms for language which are biological. We have to have a voice box located high in the throat and nasal cavity large enough to produce a range of sounds and we need a brain set up to allow

lateralization of the speech center. (Some brain functions are lateralized in other mammals also.) There are other prerequisites which are shared with mammals, like the ability to learn rapidly, especially at an early age, and parents willing to teach what they in turn have learned.

The cat brings a live mouse back to its litter of kittens. They play with the mouse, eventually kill it and eat it. The kittens have learned about mice, about the chase, about killing mice, and eating them. When the kittens grow up, they bring mice back to their own kittens. That they also learned.

-- observation, 1983

Language Development

The structure of languages, their redundancy, variability, and complexity of expression are all at the service of teaching -- and not just teaching children, but adults also. The same is true of *subjective consciousness*. Whenever we engage with others, we are constantly proposing a new consciousness with our expressed thoughts about areas of interest. These are proposals for alternate and new mind-space scenarios. They are new -- to the other person -- because what we express is our own, and seldom the mental experience of the other person. Teaching never ends.

The enormous number of constantly changing languages and the vast differences in grammars are proof enough that languages are not biologically mandated. The versatility of humans allowed languages to develop. However, although the existence of humans -- hominids -- stretches back millions of years, languages are not thought to be much older than about 40,000 years.

As a species we are deprived of a number of communication possibilities that are well-developed in other species. We have language because we happened to have made use of what we had: a voice box which can make very complicated discrete sounds, the ability to identify sequenced sounds, an inventiveness -- you might even say, playfulness -- beyond anything seen in two million years, an unlimited food supply, and lots of free time. Altogether, language seems to have little purpose until recently, when it became the basis for *subjective consciousness*, and looks more like an accident than an adaptive evolutionary trend with some survival purpose. It looks, in fact, more like a game that was played among humans, something which we readily acknowledge in our casual banter with others. [\[note 6\]](#)

All mammals communicate, and gregarious mammals do so in complex ways which remain mostly outside our ken. And it is all about food, sex, and young, and territory and enemies. Dogs, originally as wolves (100,000 to 60,000 years ago), are gregarious, and they growl, howl, and grunt, and have a dozen barks. They also use body language and facial expressions, very similar to us, to communicate. (Dog gestures are easy to learn, by the way, and can be used effectively to "talk" to dogs.) So far, so good. We do all that. We can

communicate with grunts, talk with our hands, and express ourselves with facial gestures. And, as such, we need nothing beyond hand waving and a few grunts for communal food gathering, or raising children. [\[note 7\]](#)

But dogs (wolves) also communicate in ways completely beyond our abilities. They live in a Smell Universe which is absolutely amazing and unknown to us. A wolf (dog) rolls its back on a killed animal and carries the smell back to the den -- often dozens of miles away -- to identify the prey by species, age, health at the time of death, and the age of the kill. The route to the kill is attached to the reporting wolf like a map of smells so that the home wolves need not be guided. They know what landmarks were trotted past, how far to go, and can home in on the prey during the last part of the trek. They are not led by the wolf who brings back the news.

Dogs (rats also) have a bundle of nerves connecting the smell centers of the left and right hemispheres of the brain which is 10 times the diameter of our left to right speech connection. That means a circuitry 100 times more abundant in neural connections than what we use for speech. These animals have an integrated brain capacity dedicated to smell which is thousands of times larger than our capacity altogether for vocabulary, grammar, speech, and memorized names and phone numbers.

You cannot play "peek-a-boo" with dogs, as you can with small children. You will continue to "be there" for a dog even though you cannot be seen. The three dimensional Smell Universe has a fourth dimension in time. When I come home with my dog, she sniffs the stairway space to determine if any occupant of the house has gone upstairs, and (I suppose) when. Dogs also read the emotions of other dogs (and humans) by smell in addition to using visual signals.

Dogs are carnivores, and are attuned to the sounds, smells, and movements of prey, and thus are very aware of the same among each other. We (or related ancestor species) have been scavengers and predators for about 2 million years, maybe more. We certainly should also be attuned to sights, smells, and sounds, and thus we could be expected to have developed a language made up out of these senses.

But we have no left-right connection in our brain at all for smell. In fact our sense of smell is the only one which does not cross over in the brain, unlike all others (sight, hearing, touch, as well as all motor and autonomic nerve control). Our sense of smell is very rudimentary. That leaves us with sight and sound. And here is where things get complicated. We have areas in the rear brain which are able to make minute differentiations of sounds, and especially time-separated sounds. The area makes a slight impression on the skull (or the skull accommodates) and this is suspected as being in development with *Homo erectus* and *Homo neanderthalensis*.

At that point in our development, we could tell bird calls apart, but, aside from identifying animal calls, sound identification was useless to us in hunting. We were by design a species

which roamed the edges of the savanna (supposedly) where our visual acuity (and our ability to run after a gazelle until it fell down from exhaustion) was much more important than sound. We moved from the savannas to forests and rivers where sound plays a minor role for us. Our visual acuity, however, exceeds that of dogs and wolves. We gathered food, whether plants or fish or large animals, by sight, not by sound.

Yet we have a well-developed capacity for differentiating sounds. We can tell *where* a very small object falls on a hard floor from the sound. Dogs will smell for it. We do not know the genesis of our enhanced hearing abilities, but most likely it served as a monitoring sense in communal groups. We have been gregarious forever. We have always lived in groups. We can follow a single conversation in a babble of talking voices. Eyes and hands could be used to pay attention to one task while hearing kept us aware of the activities of the group.

Our acute hearing is also of significant utility in child rearing. Our hearing is acute enough to spot the emotional content of a baby's voicing by the inflections. We can differentiate between degrees of displeasure and degrees of joy, and the whole range of other emotions and needs. (Dogs can do this also.) Our young are born in a most inept state and we need to care for them for a very long time. Next to eating nuts and berries and bringing home game, caring for children is the most time-consuming activity we ever undertook as a species. Child-rearing has probably always been a communal activity, but there are other things for the community to do as well, and since you cannot watch children constantly, sometimes you have to listen for them instead.

I don't think the start of language involved some spear-carrying Cro-Magnon coming home and having to invent the phrases, "Me-kill. Caribou. Come-with. Slice-up. Bring-home." It probably originated while watching and listening for kids, and sitting around in the spare time making up jokes, "Tickle, tickle, ha ha ha." [\[note 8\]](#)

Children have to be taught everything. Children learn through repetition, and humorous situations are the ones they would like to repeat or re-live. Whacking a child for stealing meat out of the pot, or shushing them away from hot coals, is not the type of activity adults and children would repeat just for the fun of it. But jokes and funny situations are. They are repeated and re-lived voluntarily.

If, in fact, there is anything "primitive" in language, it is humor. It runs consistently through all languages and through the speech of normal adults as well as brain-damaged people. My mother-in-law, with complete loss of expressive language and a severe impairment of receptive language due to two strokes, would still react to a funny situation appropriately.

And, additionally, there is nothing as universal as the ability to make puns. Puns come out of nowhere. They seem to arrive from some very primitive speech level. Puns seem to implicate the fun intellectual relationships between words of a basic vocabulary listing which exists in the mind. Even reasonably intelligent dogs invent jokes, but they cannot conceive of puns.

Language is not necessary to obtain food. We lived in a veritable pantry for tens of thousands of years. A sparsely populated world provided nothing but food for omnivorous humans. I believe that we developed language to entertain ourselves in all our free time, as we played. Play is a common characteristic activity of all mammals, and for children (as for all young mammals) play is learning.

It only takes two or three people to start an attempt to repeat and recall a funny situation. It takes very little to come up with a few nouns and verbs, and then you are off and running. A child moves from one-word sentences at 18 months to fully developed 4- and 5-word sentences in the span of a few months. Children who are never taught language will learn at any age, and within a few months.

A few adults can "invent" language in the same span of time. And with children around it will propagate generationally. Since it is a learned activity, it will incorporate its own teaching methods. We so readily teach children language because we ourselves have learned to teach language from our parents.

Language also propagates geographically. When talkies meet a non-talking group of people, the non-talkers will be talking in short order. This has been experienced repeatedly when signing deaf people have been introduced to groups of non-signing deaf people. They invent a common speech (differing from the signing originally used by the signers!) in a matter of weeks. [\[note 9\]](#)

The largest mystery of human language is that it is only about 40,000 years old (or much less), whereas modern humans have been around (by inference from rates of change of mitochondrial DNA) for 100,000 years. In itself that would tell you something: neither language nor grammar are biological. It is not like an appendix. It didn't "evolve" as a brain function or some neurological structure, not, at any rate, as part of the biology of our species. It evolved culturally. The rapid changes still seen in many languages today, and the enormous diversity of "grammars," also point to cultural evolution.

The biological structure needed for speech includes, besides a voice box of the proper dimensions, the enlargement of nasal passages. We don't see this in Neanderthals, but we see them fully developed in the first moderns of the archaeological record. From that point on our voicing and sound-recognition went hand in hand.

The Cro-Magnon types existed for 60,000 years (as in the Levant) using only the primitive Mousterian toolkit developed by and used by Neanderthals. And then, suddenly, about 40,000 or 50,000 years ago, we see the Cro-Magnon toolkit spring to life in southeastern Central Asia and the adjacent western Central Europe region, along with pierced shells and beads, carved ivories, limestone statues, bone needles and other household and hunting implements, decorated spear throwers, and, in Southwestern Europe, the first painted caves. None of these had ever been produced by any other hominids during the previous 3, 6, or 12 million years. [\[note 10\]](#)

The suggestion is that language suddenly developed 50,000 to 40,000 years ago. Wherever it developed, it would have spread like wildfire through adjacent populations of humans. It would have been the coolest thing next to pressure flaking. Language might have been the more easily taken up if the main attraction was the material culture of the nearby talking Cro-Magnon tribe. [\[note 11\]](#)

You have to admit that techniques like making buttonhole borers, detachable harpoons, or pressure-flaked serrated knives are not biological "evolutions" -- they are cultural evolutions. The sudden development and variety of Cro-Magnon's toolkit is *absolutely astounding* compared to the million years that Homo erectus used a single general-purpose bi-faced hand-axe as their only tool, or the uniformly sized flint "side scrapers" fabricated by Neanderthals for 200,000 years.

There are other parallel developments that are less easy to trace. Making cords, knotting nets, spinning, and weaving -- all point to a genesis in remote antiquity of about the same date. Mixing and compounding colorants were definitely within the scope of Cro-Magnon, as witnessed by the decorated caves of France and Spain and elsewhere. The first pottery dates from about the same time, in Japan. [\[note 12\]](#)

You would expect that language had something to do with that, but it is nearly impossible to describe in words how to knap flint or proceed with pressure flaking. In fact, language is not needed to pass on the knowledge of flint manufacturing or spinning but rather language is used to come up with the ideas for the uses of flint or threads. Language is descriptive, and any one description develops another, by way of metaphorical extension.

"The grand and vigorous function of metaphor is the generation of new language as it is needed. ... "

"[Metaphors] literally create new objects. Indeed, language is an organ of perception, not simply a means of communication."

-- Julian Jaynes

From language came ideas -- suddenly and in wild profusion. That is where all the new tools came from. They were "made to order." A single human with language is capable of generating and specifying a range of ideas far beyond anything the whole rest of the mammal world was able to think of collectively in a billion years -- or Homo erectus was able to generate in over a million years.

What we have to conclude is that about 40,000 years ago humans came to a new beginning. With the addition of language, the world was totally modern. Soon all the edible plants had been named, all the huntable animals had been identified, every cave had been explored and decorated. Although language is not needed for demonstrating household tasks, naming a plant is a lot easier than locating the plant as an example. Language introduced new

possibilities across the board. Anything could be invented which could be described -- tools and techniques were invented as needed.

And language allowed telling stories. We don't really know much about the stories; we only have the numerous instances of rock carvings and the painted caves which may point to such activities. When a painted cave depicts a herd of deer swimming across a river, it would certainly suggest a story activity to us, as do the cliff wall drawings in the Sahara of cattle roundups and dancing, although these last may be much later.

The Cro-Magnon toolkit coincides with the start of the last major glaciation (in Europe). Anthropologists insist that Cro-Magnon grew up during the severe cold of a major glaciation. I think that they grew up in a mild climate south of the northern glacier. More likely they had purposefully entered Europe as new hunting territory. But with the end of the glaciation it got colder and the migratory herds started to relocate northeast into Central Europe and into Northern Asia. The Cro-Magnon followed, now equipped with an advanced lithic technology for efficient hunting, portable kitchen utensils, a knowledge of the constructing of shelters, and of boats, rope, netting, and clothes, and very soon the techniques of spinning and weaving. It was language, also, which supported the social order needed for the Cro-Magnon trek eastward into Asia. [\[note 13\]](#)

Distance was no barrier in antiquity, as others have noted, and especially for hunters. By 35,000 years ago moderns had moved from Asia into all the continents faster than any species had ever spread, and in some cases much earlier. Australia was reached by 60,000 years ago.

Boat People

People spread out to get away from each other, and migrated to new areas to feed an expanding population, and this spread ideas widely. There are some clear signs of immensely wide contacts. Spinning and weaving, for example, are a very ancient practice. Spinning whorls are found worldwide and are identical everywhere. And finally there is the racial demography of Asia, with its parallel bands of three or four distinctly different human "types" from north to south, an indication of distinct groups all traveling east (or west, at an earlier time) to populate new territories -- and meeting the coastal populations which had arrived 20,000 years earlier. In the Americas we see the same bands -- linguistic in this case - - running in a north-south direction, an indication of arrivals of distinct groups via the Pacific coast.

At the U. C. Berkeley, Johanna Nichols has, for 15 years, classified languages by grammatical similarities to come up with relationships, rather than using the traditional language trees built on vocabularies. After 150 years of studies, finding relationships of vocabularies has only reduced the 5000 or more languages of the world to some 300 primitive types, with no indication of a connection between them.

The use of grammar as the connecting thread makes sense. All versions of pidgin English are identical in that the speakers use an English vocabulary overlaid on their native grammar. Grammar is very conservative, and it changes only slowly compared to words. The most astounding result of Nichols's work has been the identification of core grammars which spread up the east coast of Asia and down the west coast of the Americas. [\[note 14\]](#)

"In Nichols's mind, the picture is clear. An enormous and sustained wave of human migration started about 50,000 years ago somewhere in Southeast Asia. Over thousands of years, successive bands of people spread out from the region. They could move relatively quickly because they were coastally adapted -- they knew how to make simple boats and make a living from the sea. Over thousands of years, some carried their languages south and west through coastal New Guinea and into Northern Australia, while others moved clockwise up the coast of Asia, across the Bering Strait into Alaska, then down the west coast of North and South America."

-- Bob Adler scicom.ucsc.edu/SciNotes/9901/echoes/echoes.htm

"Simple boats" is contemporary chauvinism. It also seems clear that the trek along coastal South America was north from Antarctica. With the withdrawal of ocean water by glaciation, the coasts were cleared to reveal the plains of the continental shelves. Oceans may have been calmer. The course of travel would have been from river to river along the coasts. There are rivers every 25 miles (40 km) or so mostly everywhere. Humans stuck close to rivers because, like all primates, we require enormous amounts of drinking water. The rivers additionally were the routes inland.

Languages and Texts

In previous text I have offered snippets of historical documents in evidence on the presumption that our forebears at least had the wits to be able to keep records, even if they didn't develop particle physics or historiography. But these records and many of the later narratives cannot be read directly from our cultural perspective, which introduces the bias of modern values and the world-view derived from our particular grammars and what we think we know. It is critical to have an understanding of the worldview of the people who wrote the records of antiquity, and for this a look at the languages of those records might be useful.

I am no linguist, so this overview will be fairly brief and may not be accurate. In most instances I have only discussed some aspects of texts. This may shine some light on the underlying languages and grammars.

The language base is what forms the cognitive processes used by a people in their perception of the world. The Indo-European languages are solidly based on the concept of time as a series of "events" which flow from the future to the past through the present. The verb forms and their declensions certainly show this. We face the future. "Time is like a river," said

Heraclitus, facing upstream, "you cannot step into it twice."

However, this is not true for most languages. Many languages do not require people to recognize "time" as a flowing substance or for time to have significance. There are large differences between languages, which cause different speakers to use entirely different analytical methods in reaching an understanding of the world. There is certainly an ongoing convergence among the radically different viewpoints on the world (which can be seen as early as in Mesopotamia) and today more so with increased contact between people with differing languages.

... American Languages

Overall concepts of time are cultural (so is the "value" of logic, by the way). This was pointed out by Edward T Hall in books on cultural differences (*The Silent Language* (1959), *The Hidden Dimension* (1966), and others), dealing with personal space, the concepts of self as related to the body, and, most amazingly, difference with respect to an understanding of time.

Some of this was based on earlier observations by the linguists Edward Sapir and Benjamin Whorf of two North American Indian languages. Whorf pointed out that the first concern of Hopi is actuality, and of Navajo, the type of activity. Hopi belongs to the Uto-Aztecan language family group which includes Nahuatl, spoken by the Mesoamerican Aztecs, and the *lingua franca* of the Classical Era Maya. The language group is found in the Western United States, away from the coast, along the west coast of Mexico, and into Nicaragua, interspersed with other language groups.

The Sapir-Whorf Hypothesis (as it is known) suggests that language affects how people perceive their reality -- the content and structure of a culture is directly related to the content and structure of a language, that is, of the grammar of a language.

"The commonly held belief that the cognitive processes of all human beings possess a common logical structure which operates prior to and independently of communication through language is erroneous. It is Whorf's view that the linguistic patterns themselves determine what the individual perceives in this world and how he thinks about it."

"The -- for us -- self-evident distinction between past, present and future does not exist in the Hopi language. It makes no distinction between tenses, but indicates the validity a statement has: fact, memory, expectations, or custom."

"There is no difference in Hopi between 'he runs' 'he is running, 'he ran,' all being rendered by 'wari' -- 'running occurs.' An expectation is rendered by 'warinki' ('running occur [I] daresay'), which covers 'he will, shall, should, would run.' If it is a statement of a general law, 'warinkiwe' [sic?] ('running occur, characteristically') is applied (La

Barre, 1954)."

"The Hopi 'has no general notion or intuition of time as a smooth flowing continuum in which everything in the universe proceeds at an equal rate, out of a future, through a present, into a past.' (Whorf 1952)"

"Instead of our categories of space and time, Hopi rather distinguishes the 'manifest,' all that which is accessible to the senses with no distinction between present and past, and the 'unmanifest' comprising the future as well as what we call mental."

-- originally at newciv.org/ISSS_Primer/

From the same source, on the Navajo, and their primary concern with the type of activity:

"Navajo has little development of tenses; the emphasis is upon types of activity, and thus it distinguishes durative, perfective, usitative, repetitive, iterative, optative, semifactive, momentaneous, progressive, transitional, conative, etc., aspects of action."

Writing in *Language, Thought, and Reality* (1956), Benjamin Whorf states:

"We cut nature up, organize it into concepts, and ascribe significances as we do, largely because we are parties to an agreement to organize it in this way -- an agreement that holds throughout our speech community and is codefied in the patterns of our language. The agreement is, of course, an implicit and unstated one, but its terms are absolutely obligatory; we cannot talk at all except by subscribing to the organization and classification of data which the agreement decrees."

Hall, writing in *The Hidden Dimension* (1966), comments on the fact that Whorf became fluent in the Hopi language, which he studied for years, but with some effort. About Whorf's efforts, Hall writes the following:

"Whorf discovered part of the difficulty when he began to understand the Hopi concepts of time and space. In Hopi, there is no word which is equivalent to 'time' in English. Because both time and space are inextricably bound up in each other, elimination of the time dimension alters the spatial one as well."

He quotes Whorf as:

"The Hopi thought-world has no imaginary space ... it may not locate thought dealing with real space anywhere but in real space, nor insulate space from the effects of thought."

Hall concludes:

"In other words, the Hopi cannot, as we think of it, 'imagine' a place such as the

missionary's heaven or hell."

I am quoting Hall here to show how divergent the reality of the Hopi might be from a reality based on the Indo-European grammar of tenses. The failure in being able to imagine a place which could only exist in the mind, which Hall suggests above, seems like a failure of *subjective consciousness*, but this statement is hardly adequate evidence.

Following chapters will need to deal with translations from the Mayan and these will point out the very apparent lack of concern for sequences in time, although "history" was certainly understood. There will also be an inexplicable certitude of time existing in a rotating series with a scale of no more than 250 years. And where we would attempt to establish causal connections between events through their apparent contiguity in time, the Maya feels the need to establish events as the actions of some agent -- to the point, at times, of making up names. Both of these are pointed up above for the related languages of the Hopi and Navajo.

"I mentioned in relation to the units of measure that the Mayas did not seem to have the same concept of time as ours. This would seem strange if we take into account an overwhelming majority of inscriptions which have relation with records of periods of time. However, in the Maya language there does not exist the word 'time.' The most common expression is 'kinil' meaning in relation to the sun, or days."

-- Nexus Tzacol, from Project Ahau (Internet).

Keeping this in mind will help with understanding, even though the Mayan texts I have accessed are only available to me through translations, at times through two other languages. More on Mesoamerican texts further below.

... Sumerian texts

Neither Sumerian nor the later Akkadian is an Indo-European language. Akkadian is, in fact, a Semitic language (today classified as part of "Afro-Asiatic" which includes Arabia and North Africa). Sumerian does not seem to be related to any other language, although I have seen suggestions including Hungarian, Basque, Dravidian, and Georgian. The Akkadian speakers had enormous respect for the Sumerians, whom they succeeded, and they long used Sumerian as their official language. But we know next to nothing about Sumerian. In Sumer and Akkad there was a sense of time somewhat similar to that of the Indo-European language in that they had a past tense and a combined present and future tense -- actually a *perfect* and *imperfect* as in Arabic. But there is a notable difference in the point of view.

"... from the perspective of a Babylonian [Akkadian, Sumerian] the past lay before him or "faced him," while the future was conceived as lying behind him. ... the attention of Mesopotamian culture was directed towards the past and thus ultimately towards the origins of all existence."

-- Stefan Maul (1997) [\[note 15\]](#)

The sense of "the flow of time" is thus reversed in Sumerian and Akkadian from how we assume time to flow. The Mesopotamians "face the past," and are propelled backwards "into the future" -- a cognate of the word "back" in Sumerian, by the way. The beginnings were the only reality. All the innovations of civilization had been delivered by the Gods at the beginning of time. It allowed the Gods to retain their nearly three-thousand-year stranglehold on Mesopotamia.

... Egyptian texts

Old Egyptian is a distinctly African language (At one time called Hamitic), the language group of much of Northern Africa, and of the same family as Semitic Akkadian and others in the Sub-Saharan region. But a conservatism even stronger than in Mesopotamia shows in their lack of any need to present narratives. Although there are some chronological narratives written quite late, there seem to be no early "narratives" such as we have in Sumer, Akkad, and Babylon starting after 2000 BC. There were tabulation of kings and annual records, as elsewhere, dating to the 5th dynasty which records kings dating back to 3050 BC. But narratives seem to have developed only during the Middle Kingdom (ending in about 1500 BC), and are quoted in inscriptions in tombs for a 200-year period early in the New Kingdom (after 1327 BC) -- in a quaintly "antique" language, that is, in the style of the Middle Kingdom.

Yet Egypt, which obviously and insistently looked to the past as the only reality -- the "First Time" -- also looked forward to the pharaoh's meeting with Re, the God of creation, as a completion of the pharaoh's earthly existence. I suspect reality was understood as a cycle of existence where time revolved, and perhaps continually repeated the past. Time did not move, as it does for us. However, it is uncertain what the worldview really was, or how it could be explained in terms familiar to us.

We know more about the Egyptian attitude towards words and names. Certainly they believed in the efficacy of ceremony and the force of words. From the spells used in the tombs, and from some later tales about the use of names, we sense that for the Egyptians *words by themselves* represented a powerful magic. The preparations for burial were entirely enfolded in magic, with absolute certainty of the results -- the continued life after death -- proven, as Jaynes explained, by the voices of the dead which continued to be heard.

What seems to be lacking in ancient Egypt is our understanding that a simile is not an identity. Books about Egypt which speak of this or that "representing" something or other, are mistakenly imposing our sense of metaphorical equivalence on their use of language. The pharaoh did not represent Horus, he *was* Horus. The multiple statues of the king in his funeral temple were not representations, they actually *were* the king -- all of them. The curious identity of images with what they "represented" is probably best demonstrated by the

fact that in tombs the hieroglyphs which used images of birds or animals were faced away from the coffin (or had their legs removed graphically) so they could not advance on the coffin -- to keep the pharaoh's body safe from attack. The Egyptians had no room for metaphors.

... Chinese texts

China has a "saved" literature from 2300 BC to 700 BC, collated sometime after 500 BC. It is presented as factual, and the earliest record is a compilation, the *Annals of Shu* by Confucius, of odds and ends of surviving documents of the Shang dynasty and earlier. The first two sections of the Shu (covering dates back to 2357 BC) are clearly noted as later recollections. These start with, for example, "Examining into antiquity, we find that... ." Only the remaining sections were written at the time of the events which are described. The Shu is history.

There are, in addition, "legendary histories" of China, which are not part of the coda of the Classics. These legends and mythologies were not committed to writing until a later date (after AD 200 or 400), when a story-telling literature had become well established.

The Chinese languages do not have a "tense" associated with verbs, although there are clear indications in the texts of "when" actions occur which is fully congruent with the great complexities of Indo-European verb declensions, such as the "future past perfect." The script is ideographic, which makes it useful over different languages and more stable over time than phonetic scripts, but it is open to questions of exact meaning. Additionally, the media was impermanent -- bamboo slivers, cloth, and paper. Thus the coda of older documents has required constant transcription and has been open to endless emendation. This has left no actual documents contemporaneous with historical events, only later compilations. Additionally the script was not unified until about 200 BC under the Chin, the same dynasty which purged China of nearly all books in 213 BC. Many of these were reconstructed from memory and hidden books -- but not until much later.

The other influence on the compilations after 500 BC was the humanist and realist philosophies of the Confucianists (Confucius, 551-479 BC) and the earlier Taoists (Lao-tse, 604-531 BC). Here we are in an era of classical philosophical development. We see efforts to tame and explain the world in terms of basic forces of nature (as the yin/yang and material elements), not unlike the contemporaneous Greek efforts to displace the Olympian Gods with rational thought. This had an impact on the records which are forwarded to us, for they have been cleaned up and emptied of mythical and legendary elements. The texts were edited to be in the service of the imperial aristocracy, and only examples of virtuous deeds have been retained. The Chou had already removed many of the ancient religious specifics. The Confucianists retained only the veneration of ancestors, plus a concept of heaven as the source of all authority. The Shu is history, however, and can be believed. It is not legend, it is fact. [\[note 16\]](#)

"It was philosophers of this period [the third dynasty, the Chou, 1027 to 221 BC] who first enunciated the doctrine of the 'mandate of heaven,' the notion that the ruler (the 'son of heaven') governed by divine right but that his dethronement would prove that he had lost the mandate. The doctrine explained and justified the demise of the two earlier dynasties and at the same time supported the legitimacy of present and future rulers."

-- www-chaos.umd.edu/history/

In part the proof of legitimacy for any dynasty was the creation of a compendium of the activities of the previous dynasty to demonstrate how the previous dynasty had gone awry, and thus lost the mandate to govern the world. Thus we have very detailed (although terse) historical records from after about 200 BC, and some from 700 BC.

... Mesoamerican texts

Mesoamerican written texts were almost totally destroyed by the Europeans, and only partially reconstituted after AD 1500. What we have are four Pre-Colonial codexes of an astrological nature, with no "historical" content except as might be inferred. There are a number of Colonial period narrative texts, but they tend to be jumpy -- they do not convey the sense of the progress of time as we would expect, despite the occurrences of finely detailed counts of years in some texts. The *Codex Chimalpopoca*, for example, proceeds to list ages into the past but it seems to be mostly number magic rather than historical fact.

[\[note 17\]](#)

That the Mesoamerican narrative texts are formulaic, stylized, fantastical, and lack a cohesive narrative development may be due to the fact that the language structure does not require it. Mesoamerica presents a very large set of seemingly unrelated languages whose only structural affinities seem to be a highly developed sense of action (in verb use) and very weak tenses. Even the verb "to be" seems to be missing. But there is a strong sense of spatial relationships (topography), to be expected of a people who managed to make sense of the Tzolkin and Haab calendars as if they were spreadsheets.

Both the *Popol Vuh* and the *Annals of Cuahitlan* use a list of only "12 ancestors," which would amount to a time span of about 300 years, and use the movement of the tribe from a location of origin to a final location as the complete history of the recent world. It is the act of migration which is important, not the details, and the search for a new homeland is the only event of significance. The "history" texts of other tribes in the same region of Central Mexico also use this formula of a migration. Descriptions of epochs before the migration and arrival in a new homeland tend to be spectacular -- and may be assumed to represent celestial events rather than tribal events.

We know from the Maya that time was held to be circular, or rather repetitive. The numeric values of dates -- every day was individually named and numbered, and imbedded in a deep

series of cycles -- loom as large as events. In fact, all events were placed on a rotating platter of time, and fitted in with predictability. Human events occurred because they had happened before, and human destiny was to repeat them, with the requirement that they do so properly. This sense of repetition is the cognate of a causal model of reality which, although mostly unintelligible to us, is not different from the status of prophecy in Greek antiquity or Christianity. [\[note 18\]](#)

The Maya and Mesoamericans assumed the existence of a spirit world which ordered all things to happen at the right place in time in the material world. The Mesoamerican concept of reality involved action. All successes and failures of the physical world were caused by the actions of the Gods of a parallel spiritual world, and for the Maya (and presumably for all the peoples of Mesoamerica) the spiritual world was completely dependent on actions performed in the physical world. Man maintained the spiritual world which was in turn responsible for all causation in the material world. This was a circular arrangement where each world upheld the other and presented a chain of causation which could not be broken.

Suzanne D. Fisher, in an introduction to an English translation of Antonio Bolio's Spanish translation of the Maya *Chilam Balam*, writes, about the spiritual nature of the Maya:

"As provider of nourishment for divine beings, man has in his hands the existence of the world, which is created and maintained by the gods. In this sense neither men nor gods are perfect, since both are mutually dependent upon one another; both are insufficient unto themselves, but the dynamic harmony they constitute gives them sufficiency."

This philosophical outlook in Mesoamerica might explain the calendars with their unwieldy complexities of a dozen meshing cycles. Since the spiritual world remained essentially unknown, an almanac constituted the only clue as to what actions to take in the future. Once a small set of events was discovered to form a coincidence on the wheel of time, the concept of repeatability would yield an understanding of the relationship between the two worlds. I suspect this first happened after 2349 BC when Venus struck four times at intervals of 52 solar years. This was taken very seriously by the Olmecs. Then when, after 1492 BC, Venus again appeared at a 52-year interval (but in a "Tun-year" interval), disaster was averted, not by chance it seemed, but by human intervention in the spiritual world. If the intervention involved bloodletting and human sacrifice, then the pattern was set. [\[note 19\]](#)

Such at least seems to be the world-view of the Maya, and by extension the world-view of all of Mesoamerica. The religious culture seems to be uniform up to about 600 BC, and over a large geographical area. There were apparently differing interpretations after 600 BC, but mostly consistent among the Maya.

Mesoamerican histories do not yield much information which is sensibly ordered in time. The *Popol Vuh* is difficult to read for Westerners who expect a listing of events to follow each other chronologically. In the *Popol Vuh* the celestial ball-playing twins are repeating, with more success, the adventures of their twin fathers. It is the activity that counts, not the

sequence. The *Popol Vuh* is discussed in a later chapter.

With these Mesoamerican sources you have to search among strange descriptions and senseless concerns to find information coincident with Mesopotamian and Egyptian sources. There is plenty of solid information to be found, however, although nearly everything celebrates celestial events in 2349 BC and 865 BC, and much reads as magic run amok.

Book 10 of the *Book Of Chilam Balam Of Chumayel* is "The Creation of the World." This recalls events dating back to 5800 BC without references to the metaphorical and allegorical twists of the Classical era. All except one event is dated correctly, that is, to the same dates as can be gleaned from Eastern Mediterranean sources, by Katun periods of 20 years. See the chapter "The Chilam Balam" for more details.

With some effort three additional sections can be read as accurate descriptions of events dating back to 2349 BC (the "third creation"), to circa 10,900 BC (the "survey of the world"), and possibly to 30,000 or 40,000 years before the present. See the chapter "The Olmec Record of the Past" for more details.

The *Chilam Balam* is also one of only three historical documents of the Maya, the others being the *Popol Vuh* and the engraved texts at Palenque of circa AD 700. Some of the text of Palenque points to events in the 24th century BC, which can be aligned with what we know from other sources.

Subjective Consciousness

What I have tried to show above is the variation in languages of different peoples (their grammars), which would have had a direct impact on their understanding of the world. Yet all of them used language to achieve *subjective consciousness* -- some earlier, some not until very late.

I have introduced the concept of *subjective consciousness* as culturally acquired in earlier text, and made reference to Julian Jaynes. Perhaps a very brief review of his work would be called for here.

I would urge anyone to read Jaynes, at a minimum in order to reach an understanding of *how* we think -- through metaphors, narratization, and spatial fantasizing -- and also how many judgments and solutions to problems are reasoned out without conscious awareness, that is, without what we would otherwise consider as "thinking." As noted by Jaynes, actual "conscious thinking" represents a thimbleful of the gross volume of all that we would consider as "thoughts."

Jaynes spends the first chapter of his book in telling what consciousness (*subjective consciousness*) is not. It is not a copy of what we experience; it is not the source of concepts;

it is not needed for learning; and it is not necessary for thinking or reasoning. It is a difficult chapter, for much of what we hold dearly as the core of our innermost mentality is removed as support of consciousness.

... Basis of Consciousness

Language is an absolute prerequisite for *subjective consciousness*. Language is a system of naming which begets other names. It is ever-expansive, especially because the names for anything new are metaphorically related to things already known (and named).

But language is not enough for consciousness. After all, many animals use languages but can only conceive of the present tense and the near future. "Let's eat; let's play; let's screw."

*"Arf arf, arf arf arf,
the mailman is at the door,
he is going to kill us all."*

-- the dog

Here the dog, in her limited consciousness, is imagining the worst for the next few moments, as dogs have done for 100,000 years, be it marauding bears invading a campsite or evil mailmen tampering with the mailslot. But the imagined future for a dog does not extend much further ahead. We, on the other hand, can displace our "thinking" far beyond the present or into the past, reconstructing remembered or imagined spaces. But most importantly, our minds can race through many alternatives (of "who is at the door?") and make rapid evaluations -- all based on placing a substitute for ourselves into these alternative spaces.

But what are these mental "spaces?" The spaces of *subjective consciousness*, like language, are also created metaphorically. The general metaphor in use here is the *analog*, where every part of the "real world" is represented by a corresponding part in the model -- the mental space of *subjective consciousness*. It is like a map: the map reduces real world geography to marks on a paper, and the map in turn can be inspected to determine spatial relationships of the real world.

These spaces are constructed and "observed" by us, as if we are situated within them, and are thus inhabited by a copy of ourselves, an "analog I." You can even step back to see this "I" from some distance as an "analog me." So, to complete the definition of *subjective consciousness*, it requires the individual creation of an "analog I" in the expanded mind space. It is a facility so familiar to us that it is difficult to think of yourself actually engaging in "subjective consciousness." "Subjective consciousness" is to be distinguished from "self-consciousness" or "self-awareness" which is observable in many animals.

Now we have *subjective consciousness* as we understand it: a focus on the specifics of a space or an action, seemingly located in the mind, specifically in the left hemisphere, and using an "I" which is able to move about through actualities and possibilities and evaluate alternative courses of action based on probable outcomes. And in these spaces we can shift time. We can determine future actions (as yet uncompleted) and also review past actions (making up the elements of an operating space called "memory"). These evaluations are the level of "judgment" of which the verbal left brain is capable -- and at which it is very good.

Subjective consciousness is a focus which completely knits over the chasms between spatial locations (and times, also) in your mind -- to make it seamless to the point of not ever being able to be conscious of not being conscious. It reorganizes memories to make them seem like "looked at spaces," rather than actual sensory impressions. It forces you to "remember" anything you have done by taking an exterior spatial view of the activity. Even mathematical concepts are evaluated as spatial relationships. Jaynes claims there is no *subjective consciousness* except that which is represented by imagined spaces accompanied by the analogs of normal human actions -- we view, review, fit, weigh, and manipulate concepts, and all as actions. Time is also viewed spatially, as a continuous space of differing gradations. [\[note 20\]](#)

Subjective consciousness is a focus which only occasionally actually includes awareness of sensory experience. Not that you cannot shift your consciousness to something that catches your attention or become acutely aware of some part of your body -- but it is another (unconscious) part of the brain which tips you off, and then you shift to inhabit an "analog real space," moving your "analog I" to just behind the eyes. [\[note 21\]](#)

More importantly, and despite what you think occurs in your mind, *subjective consciousness* excludes the formation of concepts, so-called reasoning, and most judgments about physical objects and other people. There is no recollection, for example, of how you managed to drive your car home, and there is awareness, but no "thinking" involved in panic reactions. A later review of a newly constructed memory will add all the "reasoning" that determined your actions. All immediate "thinking" is done in the background, unconsciously, and by the right brain. You don't have any awareness of this until the conclusions are transmitted to the *subjective consciousness* of the left side. [\[note 22\]](#)

We only apply logic (as "reasoning") after the fact. Similarly, ask any artist where ideas come from -- they appear out of thin air. Ask Einstein where his concepts came from -- they came from no-where, usually while shaving. Einstein remarked that he shaved very carefully, for new ideas would pop into his mind and often startle him. This happened during other mundane activities also.

"I thought of that while riding my bike."

-- Albert Einstein

None of consciousness is anything like what a wolf does to chase down an elk, which is totally automatic, involves quick judgments and pre-guessing the moves of his prey, and who knows what else. If you or I did something as wild as that we would make all the right moves and never "be conscious" of them. What we *would* be conscious of is the overview of the real space we would be operating in (chasing an elk), but seen as if we were watching a movie, with ourselves simultaneously as actor and viewer.

Our "consciousness" could be elsewhere while we were chasing the elk. This condition is easily recognized in driving a car, where we make all the right adjustments to traffic, yet are "lost in thought" most of the time, lost that is, in the musings of our left-brain consciousness. We could be considering the opening notes of some piece of music. The car trip (or elk chase) would still be completed with the same efficiency -- our body would still make the correct decisions on how to move, where to turn, when to stop. And none of it would involve "thinking" as we commonly understand it.

The right brain can perform any "learned" activity blindly, like playing a piano, or driving a car. But it has trouble with new situations. Evaluating anything new is the task of *subjective consciousness*. In fact, *subjective consciousness* will hinder automatic activity. Try becoming aware of your fingers while typing. You will start making mistakes or even come to a halt. Become aware of someone looking at you while you are walking and your step will falter and your shoes will scuff the ground.

Development of Subjective Consciousness

What Jaynes next suggests is that *subjective consciousness* is learned by children at about age 7 or 8. It involves recognizing themselves as seen by others -- an "analog I" which is then internalized and placed into the space of the imagination. This analog can move around, perform actions, evaluate results, and can even vault through time. Parents constantly guide small children through numerous "what-if" situations and badger them with metaphorical constructions and reminders of remembered events, in effect *teaching them subjective consciousness*. Part of this is to teach to the child what others might be thinking. Since *subjective consciousness* is learned, it is cultural, not biological. And, Jaynes claims, because *subjective consciousness* is language-based, it is easily learned by children as soon as they gain some facility with the expansion of language into metaphors. [\[note 23\]](#)

Subjective consciousness is deeply imbedded in the teaching of *subjective consciousness*. It is as if we could say that "the expression of subjective consciousness" is "the teaching of subjective consciousness." In this respect it is no different from our teaching of language skills.

Historically, Jaynes places the creation of the "internal I" after the development of written texts. It was also in response to a population expansion of the Middle East, because the other source of *subjective consciousness* is meeting new people -- not those familiar to us. For the

most part we don't look at those familiar to us, nor do we question how they see us. Having to meet strangers causes you to wonder how they are seeing you and this results in the creation of an "analog I" as the way you imagine others see you. By reflection this then becomes the way you imagine yourself. [\[note 24\]](#)

The quality of *subjective consciousness* changes over time. Since it is cultural, there is no biological evolution involved, but *subjective consciousness* does evolve. Jaynes has documented the radical changes over the span of a few hundred years during the first millennium BC in Greece and the Levant, and noted the changes in South America over the span of a few months. The quality of *subjective consciousness* will be different from one person to another, although any social group with the same language and a common culture will for the most part share a common *subjective consciousness*.

Both the left and right hemisphere of the brain can understand speech. However, only the left brain can speak. The right brain specializes in seeing objects in context and has a sense of spatial relationships. The left brain concentrates on specific objects but is able to apprehend and order linear patterns, including, of course, speech and stories. [\[note 25\]](#)

That is a sort of shorthand, for the right hemisphere is also involved in speech -- operating the mouth and vocal cords. And the right brain can talk to the left brain in "voices" which are either heard silently in the consciousness of the left hemisphere, or pass right through and are spoken. You will see yourself doing this, for example, in greeting familiar people, but you will also find yourself mouthing off at the most inopportune moments.

The "voices" from the right brain are the remembered admonitions of your parents, and later, your superiors. It is your right brain that brings to mind such things as "it is time to go," or "close the door." It is the right brain that always has the seemingly appropriate solutions, for it sees things in an overall familiar context and knows what to do in any situation which is not novel. It is also the more creative -- solutions to many "computable problems" come from the right.

The left brain concentrates on individual objects often to the total exclusion of context, but works easily in linear format -- like remembering phone numbers as one unit (which is but a larger decontextualized object), remembering songs and stories, and placing all the words of a sentence in the right order when you speak. The left is verbal, linear, and, because of the imagined spaces that can be examined, analytical. But in actuality it probably spends most of the time just meandering. The only conscious "thinking" we do is musing and reflecting -- always by means of imagined actions in imagined spaces. The right brain often gets annoyed with the left, and you will hear yourself muttering comments on your lack of directed thinking or your behavior.

Jaynes points to the left brain as the center of our consciousness: we are "aware" of left brain activities, but never of the right-brain. When the left brain gets into a bind on a problem, it is the right brain which often spits out an answer to the left-brain's consciousness -- "It popped

into my mind."

In an age before written texts, or before reflection on the self as seen by others, the right brain "spoke" -- actual words were heard by the left side. We still hear these admonitions today, but mostly silently, "close the door." The wonderfully common-sense right hemisphere at times has to warn the left half of something, or get its attention. Jaynes suggests that using heard speech might have been a shorthand used by the right brain because the rear commissure connecting the two halves is only a few millimeters in diameter. By comparison, the olfactory commissure (which we do not have at all) in dogs and rodents is, as I mentioned, 10 times that diameter, thus 100 times the area. These animals integrate left and right brain functions surrounding smell much better than we integrate our verbal functions.

Our right to left communication today is often in visual concepts (I suspect), rather than words, although we still hear our mind "say" things -- quietly. It can be guaranteed that almost all statements of "correct behavior" which jump out of our mouth are initiated in the right brain. However, frequently they are inappropriate. The right brain does not deal with anything novel and cannot analyze the nuances of a new situation and peruse the alternate possibilities which the conscious left brain can imagine. Often you will find yourself saying, "My first thought was ... but upon further consideration...."

... Instructions from God

Throughout the "Era of the Gods" and for 2000 years after, these instructions from the right brain were "heard" as the voices of the Gods: instructions on crop management, irrigation, and whatever else was appropriate for daily life of a community. There were many thousands of people in Mesopotamia and Egypt involved in agriculture, distribution, and trade. These were also the first large populations to do repetitive backbreaking communal tasks. Grain production requires that type of work, but it was done without reluctance because the Gods were held as real, superior, and absolute in power, and a slave mentality developed. Society was to continue as it was: with people sowing and reaping the fields of the Gods. Early inscriptions insist on this.

Jaynes points out the "authority" of spoken words, and he supplies extensive data from schizophrenics and commissureotomized patients. The right brain under these conditions issues commands, not solutions or suggestions. This is not different, he claims, from what was experienced by the people of Mesopotamia and Egypt up to about 1000 BC.

It is the development of written texts (claims Jaynes) which opened up a new vista: the possibility that words could be independent of a person and thus "voice" could be abstracted into silence. This is an amazing concept which filtered down into society over the next few hundred years as parents modeled such silent consciousness to children. And with that the voices disappeared. [\[note 26\]](#)

... Differences

As examples of the differences in consciousness of vastly different people, compare the war edicts and bragging of the Assyrians with the contemporaneous "Spring and Autumn" Wars being waged in China. The wars were no different -- and the same example of the warring Gods stood before both groups in the skies overhead. But the attitudes were completely different. The Assyrians were bellicose and cruel and insisted on devastating the peoples they had conquered -- always over matters of tribute. [\[note 27\]](#)

"Throughout the Assyrian war records runs the monotonous mantra. 'I destroyed, I devastated. I burned with fire'. No hint of mercy or pity here; but ... repetitive and total conquest. Assyria, often likened to the Nazis, was a thoroughgoing military nation, highly disciplined. Her characteristics were destructive invasion, deportation and taxation."

-- Originally from CIAS at specialtyinterests.net.

The Chinese states went to war over the same sort of resources, but the tactics of war and settlements took a different course. By 400 BC there was already a conscious effort to view tactics philosophically and write about them, as follows. The Chinese in fact have never favored warfare.

"In general, the method of employing the military is this: Preserving the [enemy's] state capital is best, destroying their state capital is second best. Preserving their army is best, destroying their army is second best. ... attaining one hundred victories in one hundred battles is not the pinnacle of excellence. Subjugating the enemy's army without fighting is the true pinnacle of excellence."

-- Sun Tzu, opening lines *The Art of War* (circa 400 BC).
[\[note 28\]](#)

... Points of Disagreement

For many people language is so obviously and unquestionably innate that the book by Jaynes will make absolutely no sense at all. And without the idea that language could have evolved culturally, you cannot understand the idea of a cultural evolution of *subjective consciousness*. Growing up bilingual helps, for it provides some perspective. But most of us fail to examine even our own "word-thinking" and the language of others. Another contributing factor is the incredible chauvinism we have adopted to separate ourselves both from animals and from the past.

Other people will dismiss Jaynes over the details of the *Iliad*, which he uses as his start-up example of a change in consciousness. The objections involve arguments about when the

Iliad was written, whether Troy existed at all, and how a group of Greek pirates could possibly wage a ten-year war. Also, since Jaynes is using 1100 BC for the Trojan war (a date first suggested by Herodotus), he is forced to assume that the transmission of details of the epic was via some sort of semi-conscious bards. This follows a theory of "bardic transmission" dating from studies of Balkan epic poetry earlier in the 20th century, but the exact transmission from bard to bard has since been disproven. [\[note 29\]](#)

I have other differences with Jaynes myself. I object to Jaynes's insistence on the need for kings and leaders. It seems to be a peculiarly Western outlook that you cannot have a village of 200 people without some sort of control, much less a city of 10,000. Often he slips into generalization like "the mechanism of social control." Archaeologically, it appears that there were no leaders, kings, or pharaohs in control before 3100 BC. However, we do not need to look among antique or primitive societies alone for egalitarian societies. The precursor of the Dutch Republic, a collection of city-states, managed adequately without promoting anyone to absolute power for several hundred years. Humans will cooperate -- it is natural for us as a gregarious species, although it is also natural to demand leadership in times of social stress, as happened after 3100 BC. The idea of "individuality," which today makes us almost perversely independent and uncooperative, is a very late concept in Europe, probably dating to well after the 16th or 17th century AD. [\[note 30\]](#)

Jaynes uses the idea of "social control" to suggest how the voices of the Gods -- which most definitely occurred -- might have started and been located in the right hemisphere of the brain. He resorts to the suggestion of an "evolution by natural selection as a method of social control." But this is an unclear concept. I would suggest that "natural selection" is not an issue, primarily because the need for "social control" is not a fact.

I would suggest, instead, that the structure of the mammalian brain is already lateralized for spatial and linear functionality, respectively in the right and left hemisphere. This is in itself enough to naturally place speech functions -- which require linear order -- on the left. In addition, the speech functions are fluidly relocatable, which I think would argue against an evolutionary mandate. Some people have speech functions located on the right, as with those who suffered left hemisphere damage at an early age, and with some left-handed people.

What Jaynes, publishing in 1979, was not aware of was the research by Talbott in 1980, and the subsequent expansion on this over the next twenty years, showing the enormous cultural influence of the planets standing in the sky close to Earth, which were universally understood as the Gods who directed all human activities -- the very Gods whose voices Jaynes places in the right hemisphere.

Jaynes instead uses marked graves in the Neolithic (from 7000 BC), the rather occasional extravagant graves of "kings" (which may be the misdated Sumerian pit graves of 800 BC), and the display of the skulls of the dead in homes (and later temple structures) in various locations in the Middle East, to suggest that the hallucinating voices of the dead continued to be heard. In Egypt during historic times it was certainly held true that the voice of the dead

pharaoh remained to be heard to advise and direct. But this period follows directly on the prehistoric era when, for a thousand years or more, mankind was confronted by the image of a large head looming constantly above the north horizon.

We have no idea of the function of all the variously displayed and decorated skulls. In the era before 3100 BC, the skulls might have been honored dead relatives, parents, or they might have been enemies or sacrificial victims. The images in the sky after 4077 BC must have had an enormous influence on humans, and humans, as ever, imitated what they saw. The exact measure of this is not revealed until after the head in the sky had disappeared. If anything induced the "voices of the gods" to be heard via the rear commissure between the right hemisphere and the left, it would have been this constant thousand-year image of a globe in the sky.

Advantages

We could ask, What is the advantage of subjective consciousness? Obviously, in the remote past, it was used to get through change, whether cataclysmic change or the need to live through social change. But, we could ask, what is the utility in today's milieu?

From my perspective, *subjective consciousness* allows traveling through time, visiting distant places, and imagining cosmic relationships. It also allows navigating the complexities of relationships, imagining technology not yet in existence, and selling products to those who do not need them.

We should also not neglect the possibility that the *subjective consciousness* of the left brain aids the normal background processes engaged in by the right brain. Certainly we know that the right brain knows whatever the left brain knows, and is able to work out solutions to questions that the left brain just cannot handle. Einstein's care in shaving is an example of the startling revelations which can come to consciousness as if out of nowhere. Einstein's brilliant ideas certainly were not limited to parental admonitions.

I suspect that a salesman who has gone through attempts to enter the mind of his customers will have offered all of these scenarios to his right brain. They will be stored somewhere and can be accessed as needed. The best approach for a particular customer will be selected and presented to *subjective consciousness* as if out of nowhere -- based on an almost instantaneous analysis of the customer's psychological state. Considering the speed with which the right brain can operate, this certainly is a more likely process than having to wait for *subjective consciousness* to take the time to trip through a number of imagined scenarios. Everyday speech and the creations of poets and artists must be generated like this. I also suspect that the right brain today, rather than using speech to alert the subjective consciousness, as was traditionally done, might also use images to a greater degree. But of course how *subjective consciousness* operates, and what its particular qualities are, depends completely on how a person is brought up in a particular social context, including the

qualities of a particular language and grammar. We don't all think alike.

Disadvantages

We can also ask, What have we lost by giving up the bicameral paradigm? Jaynes addresses this in the third section of his book, "Vestiges of the Bicameral Mind in the Modern World," specifically under the topic of schizophrenia with the subtopic "The Advantages of Schizophrenia" (page 426).

What is interesting here is that Jaynes very convincingly equates schizophrenia with a complete loss of subjective consciousness: the loss of the inner space of the imagination, the loss of the self reflective 'I', the loss of the ability to narratize. It is a reversion to the pre-conscious bicameral paradigm.

"Another advantage of schizophrenia, perhaps evolutionary, is tirelessness. While a few schizophrenics complain of generalized fatigue, particularly in the early stages of the illness, most patients do not. In fact, they show less fatigue than normal persons and are capable of tremendous feats of endurance. They are not fatigued by examinations lasting many hours. They may move about day and night, or work endlessly without any sign of being tired. Catatonics may hold an awkward position for days that the reader could not hold for more than a few minutes. This suggests that much fatigue is a product of the subjective conscious mind, and that bicameral man, building the pyramids of Egypt, the ziggurats of Sumer, or the gigantic temples at Teotihuacan with only hand labor, could do so far more easily than could conscious self-reflective men."

Thus schizophrenia provides a window on the behaviour of humans of before 1500 BC and much later in some other regions.

All indications are that this condition of hearing the voices of the gods generated by the right hemisphere of the brain was heard in plain language by the left hemisphere. Jaynes places the development of language in the Upper Paleolithic. The current estimates by linguists place the genesis of language at about 40,000 BC. John Halloran, an expert on the Sumerian language, convincingly suggests a range of 9,500 to 8,000 BC. See Halloran's site at [\[www.sumerian.org\]](http://www.sumerian.org).

Children

Lastly, let me add some notes on children and *subjective consciousness*. Children learn language from adults who, on meeting a child, always test the level of the child's language abilities and then switch to a "caretaker language" to continue conversing. A "caretaker language" is grammatically slightly advanced beyond the level of the child. We have all learned this teaching technique, and we use it automatically with children. People who "baby-talk" to children are those who have made no effort to gauge the child's current

abilities. [\[note 31\]](#)

What Jaynes suggests is that *subjective consciousness* is learned similarly to the way in which language is learned -- parents teach children *subjective consciousness*, and have done so actively since about 1000 BC. In the interaction with parents (*subjectively conscious* parents) children are constantly confronted with snippets of real and imaginary situations which, over the course of years of exposure, and graded to their mental abilities, suggest the possibilities of imagining what they might do under a proposed situation. What is always suggested to the child is what actions they might take -- because all "thinking" in the mind involves an analog of actions in the real world. Thus both the analogical "spaces" and the actions to be performed in them are constantly put forth to children, and this is done by us with the same lack of awareness that we use with a graded caretaker language. This process also forces upon a child the recognition that others (mainly their parents) see them in their mind. We often identify the age of seven or eight as the first glimmer of "consciousness" in children. It is, in actuality, the first glimmer of their awareness of *our* consciousness.

[\[note 32\]](#)

It is instructive to observe children 4 to 7 years old, although the state of *subjective consciousness* depends very much on their verbal abilities and the interaction they have with their parents and other adults. There seems to be a difference also between girls and boys, perhaps because girls (in our society) are more engaged in person to person relationships by their mothers. Pre-conscious children have recognizable behavior patterns which might be reflected in the following to various degrees. The following notes are my observations. (They are not from Jaynes.)

- They lack any clear memory of the past except for events they have been told about and some critical events which may have been reenacted mentally. Pre-language "memories" of events are almost entirely absent in everyone, for most memories are "constructed" by a subjective consciousness after the age of 7 or 8.
- They show little of the self-consciousness which would result from being able to see yourself from an exterior perspective -- as being seen by others. Children are self-aware, as all mammals are, but are unable to displace this to an exterior perspective. Their behavior is simply regulated by parental admonitions and the parental controls of shame, guilt, or embarrassment.
- The imagination of a child, as exercised in play, is often unbounded by reality and often lacks a measure of time and lacks themselves as an involved actor. Older children will often "correct" the play fantasies of younger children, in effect mimicking parental teaching of *subjective consciousness*.
- They are often very opinionated, blurting out the opinions of their parents in lieu of any original "thinking" on a subject, a trait which often carries far into adulthood. Original thoughts on a particular subject would involve being able to create imagined spaces for action in the mind and walking an "analog I" through these spaces to evaluate alternative outcomes.

- They will interrupt adult conversations with non-sequiturs, for there is no ability to narratize the present as a mental space in which they can fit themselves and observe the (real) space as if from afar (that is, from the mind), and to narratize what others might hear or might be thinking at the moment.
- They often have hopelessly inadequate concepts of space and travel time ("Are we there yet?"). Children experience a dilation of real time which adults do not notice. Children (young children, especially) do not have access to the musings of *subjective consciousness*, with which adults fill real time to replace the second-by-second experience of actual time.

Yet children are fully functional. They learn to read and do math. They learn skills. They learn how things work, and how to interact with others. They can create and appreciate jokes. They know who they are. But the guide to their actions is the voices of parental admonitions and attitudes which were heard, remembered, and recalled. It is, in fact, the right hemisphere which does this for any predictable situation.

Endnotes

Note 1 --

Sherwood Washburn is paraphrased by Edward T. Hall, in *Beyond Culture* (1976), from S. L. Washburn, "Primate Field Studies and Social Science," in Nader and Marettzki, *Cultural Illness and Health* (1973). He is talking about primate young (as an area of study), but this could be extended to adults also. Adults also learn from their peers.

[\[return to text\]](#)

Note 2 --

That is not entirely true. Pointer dogs point with their nose and tail, and the young will learn from older dogs. I have only taught one Rottweiler dog to follow the direction of a human's pointed finger.

Humans understand and answer questions by 18 months.

[\[return to text\]](#)

Note 3 --

The following are from an Internet source which I have not tracked. Obviously the original author has just split up mental functions by opposing approaches, which, however, has little to do with what seems to be happening in actuality. The qualities listed below are almost all incorrectly assigned, the case being that either the two are reversed from inferences we can make, or both qualities belong on one side. I'll note the obvious reversals below (marked

"rev"), followed by some comments.

Consciousness is located in the verbal left hemisphere, where speech generation is also found, and which operates the right hand. The silent right hemisphere is mostly incapable of speech although it can understand language. It operates the left hand. But the silent right is capable of close reasoning, data evaluation, and rote endeavors. It can type without thinking, operate a car, play music, unlock the door. There are 15 items listed at the original; I'll go through these by relisting them as follows:

	LEFT	RIGHT	
1	uses logic	uses feeling	(rev)
2	detail oriented	"big picture" oriented	(?)

(1), (2): **uses logic/ uses feeling; and detail oriented/ "big picture" oriented** -- Animal studies indicate that the right hemisphere, not the conscious verbal left, uses "logic," is "detail oriented," and bases decisions on "fact" (see below). "Detail oriented" is, however, also a left brain function since consciousness can only focus on one thing at a time.

	LEFT	RIGHT	
3	facts rule	imagination rules	(rev)

(3): **facts rule/ imagination rules** -- This is certainly reversed. The verbal left brain operates entirely in the realm of the imagination. The right does not. The right operates on facts.

	LEFT	RIGHT	
4	words and language	symbols and images	(?)

(4): **words and language/ symbols and images** -- The verbal left brain is the only one that can speak, but certainly the right brain also understands speech. The status of "symbols and images" is ambiguous, since some of the back communication of the right brain may be in imagery, but it can also be in words that pop into your head (and at times into your mouth), as it can be in sweeping feelings. "Symbols" I am not clear on. Symbols are abstractions, and thus probably in the domain of the left brain, which uses abstractions to jump through mental spaces which would be too time consuming to traverse in detail.

	LEFT	RIGHT	
5	present and past	present and future	(rev)

(5): **present and past/ present and future** -- It is the future which is accessed by the conscious left brain, as well as the past, including the imagined past or future -- especially this last. The silent right brain deals with the present, and with the past only in that current action is based on what was learned in the (real) past.

	LEFT	RIGHT	
6	math and science	philosophy & religion	(?)

(6): **math and science/ philosophy & religion** -- Math and science are created and

manipulated in the space of the imagination, and thus represent left brain activities. But philosophy probably belongs there also. Religion (but not theology), in that it is unsupported by any reason, belongs on the right as accepted dogma. This suggests that science, if it is learned as handed-down dogma, also is a function of the right brain, and exhibits itself in the manner of unreasoned value judgments no different from what has been learned to be acceptable in social exchanges, or as religion.

	LEFT	RIGHT	
7	can comprehend	can "get it" (meaning)	(?)
9	acknowledges	appreciates	(?)

(7), (9): **can comprehend/ can "get it"; and acknowledges/ appreciates** -- I'm not sure what to do with these. All of these are mental judgments, so that I would probably attribute them to the operation of the conscious left brain. The right brain is not judgmental, nor does it form meta-theories about knowledge. Not, at least, without your asking it to do so.

	LEFT	RIGHT	
8	knowing	believing	(?)

(8): **knowing/ believing;** -- knowledge is securely lodged in the verbal left hemisphere in that an analysis has been performed which supposedly lines up the elements of a syllogism to support the "facts." But almost always knowledge is generated by the silent right brain. Belief is a matter of conviction and has no more status than fantasy.

	LEFT	RIGHT	
10	pattern perception	spatial perception	(no)

(10): **order, pattern perception/ spatial perception** -- The verbal left brain deals with order, as in the word order of speech, and this could be extended, along with pattern recognition, to the mental arrangement of external objects or events, although, I should warn, this is dependent on the grammar in use. That would by default assign "spatial perception" to the silent right brain, but this might be an inference based on the absolutely amazing speed with which familiar situations are evaluated, plus the ability to review all the relevant data of a field of study.

	LEFT	RIGHT	
11	knows object name	knows object function	(yes)

(11): **knows object name/ knows object function** -- Probably correct, in that it has been repeatedly shown that the silent right brain has difficulty naming objects, although it will recognize their use.

	LEFT	RIGHT	
12	reality based	fantasy based	(rev)

(12): **reality based/ fantasy based** -- This is exactly reversed. It is the conscious left brain which deals in fantasies, whereas the right brain remains rooted in reality. But because it

bases actions on learned situations of the past, the right brain becomes deadlocked in new or unfamiliar situations, whereas the conscious left brain can work through possible solutions of how to handle new situations.

	LEFT	RIGHT	
13	forms strategies	presents possibilities	(no)

(13): **forms strategies/ presents possibilities** -- Both of these are functions of the conscious left brain. The right brain does not deal with options.

	LEFT	RIGHT	
14	practical	impetuous	(rev)

(14): **practical/ impetuous** -- This is also reversed. The active imagination -- what I have elsewhere identified as *subjective consciousness* -- makes the conscious verbal left brain "impetuous" while the right brain remains "practical." But because of the speed with which the right brain arrives at a course of action, it might be inferred that it is acting impetuously.

	LEFT	RIGHT	
15	safe	risk taking	(rev)

(15): **safe/ risk taking** -- Again, the applications are reversed. The conscious left brain takes risks often based on flimsy theories of how things work. The theorizing (tracking possibilities) is so much part of what we perceive as "consciousness" that we just cannot ignore it. We tend to think of these theories as "reasoning" and value them as the highest order of mental activity. This is how gamblers lose, and how bad investments are made.

[\[return to text\]](#)

Note 4 --

The quoted text is from an article adapted from the book which appeared in *Scientific American Mind*, June/July 2008, "Spheres of Influence" by Michael Gazzaniga.

[\[return to text\]](#)

Note 5 --

Our main distinction as a species is that we are strongly neotenized, which doubles our lifespan and flattens our face. Cats are also neotenized, living twice as long as a cat-sized mammal normally would. We also lost our fur, our tail, and the ability to produce vitamin C, but have gained our longevity for the sake of our oversized and helpless babies, and to allow for their long period of learning. The other outstanding difference -- bipedalism -- is certainly common among birds, marsupials, and dinosaurs. What we hold as "racial" distinctions (body size, hair, skin color, nose and eye shapes) have generally been held to be the result of 30,000 years of environmental isolation. For paleontologists only the inside slope of the front teeth is a clear racial distinction.

[\[return to text\]](#)

Note 6 --

Steven Mithen, in *The Singing Neanderthals* (2006), attempts to make a case for the evolution of language based in part on music and dance. The book involves a lot of guesswork and unfounded suppositions about prior hominids in an attempt to build the case for a slow evolution from natural selection. There is no "slow evolution."

Jaynes also attempted to make a case for how language might have developed, but too specific to Cro-Magnon, guesses about the effect of the European climate, and "selective pressures" to make much sense.

Alfred de Grazia, I feel, is closer in observing:

"Here is an area where evolutionary thought is especially self-contradictory and, consequently, slippery and evasive. It can only get from one small change to the next but cannot get from the beginning to the end; it can explain some intra-species changes, like horse-breeding and the Beltsville turkey, but it cannot explain a major development. No known mechanism directs a long string of slight modifications in the germ plasm. Even if we were to concede that the jump from hominid to human were only apparently large but was biologically small, human genesis would admittedly be a hologenetic occurrence; when it occurred, hominid life changed drastically; it speciated."

-- *Homo Schizo, Human and Cultural Hologenesis* (1983?)

[\[return to text\]](#)

Note 7 --

About gestures, Edward Sapir, in 1972 wrote: "... we respond to gestures with an extreme alertness and, one might almost say, in accordance with an elaborate and secret code that is written nowhere, known by none, and understood by all." Quoted by Tim Friend in *Animal Talk* (2004).

About dogs, R.A. Fonda, in "Speculation on speciation" originally at rafonda.com, writes:

"In East Asia, by a hundred thousand years ago, casual scavenging of predator kills had developed into systematic exploitation of the wolves' capacity to pursue fleet game. That led to domestication of dogs, who were, themselves, differentiated from wolves by neoteny. They matured into an amenable creature that could pattern on humans as pack-alphas, and behave with 'puppyish' submission even when mature."

Fonda is perhaps too glib about dog behavior. Domesticated dogs are still carnivores and wild animals, and they are certainly not neotenized. Their submission is not all that puppyish, but only as it benefits their own pack-member priorities. Their benefit to humans comes from their carnivore brains which are able to almost instantaneously reach conclusions based on

integrating many diverse small environmental cues, and as a result of great value in hunting. Dogs can also "read" humans with amazing proficiency as a result. But most behavior is still all about search, chase, bite, rip, and eat. Don't get your hand caught in that sequence.

[\[return to text\]](#)

Note 8 --

From various considerations, John A. Halloran thinks that the Sumerian language was invented as a game by women, around 10,000 BC. That would place the genesis of language at the leading edge of the first settlements dedicated to mixed gathering/hunting and farming. He identifies some base words with earlier building structures in Iran and at Catal Hoyuk.

See [\[www.sumerian.org/prot-sum.htm\]](http://www.sumerian.org/prot-sum.htm)

[\[return to text\]](#)

Note 9 --

Halloran has suggested that the Indo-European language group is a secondary effort, that is, a language based on the active implementation of the "concept" of a language, whereas Sumerian shows the signs of a language invented from meanings associated with the voicing of vowels and consonants. In his study of Sumerian, he has shown that the basic words of that language originate from the meaning inherent in the sounds and the shapes formed by the mouth and tongue. Sumerian thus may be an original "proto-language."

"Biological forms must be descended from ancestral forms. This cannot be true for languages for an infinite time depth. The method of glottochronology must break down when it reaches the event horizon at which a population went from nonspeaking to speaking. In some cases, just the concept of speech will have inspired a population to invent their own language. In other cases, a population will have built their new language upon a repertoire of elements taken from an existing language."

-- John A. Halloran, at [\[www.sumerian.org/prot-sum.htm\]](http://www.sumerian.org/prot-sum.htm)

Studies of the basic meaning of words of Indo-European languages show little or no relationship to the physiological content of the mouthed sounds. It would be suspected that the prototype Indo-European language was created much like Northern European alphabets, in that they were derived from the *concept* of writing, and not in imitation of Mediterranean alphabets. The glyphs used by the Romans or Greeks, like "alpha, beta, gamma, delta," originated from "ox, house, camel, river mouth" -- named objects signifying the sound of the letter. The Northern European alphabets do not show a derivation of glyphs from named objects.

[\[return to text\]](#)

Note 10 --

There are some Cro-Magnon-like developments at a much earlier period (70,000 ya) in South Africa. They are typically Cro-Magnon-like in that they seem to represent short-lived local fashions without any notable utility.

[\[return to text\]](#)

Note 11 --

Language is passed with ease to people who do not speak because the whole structure of language is imbedded in the task of teaching language. Without this our children would only learn with difficulty.

[\[return to text\]](#)

Note 12 --

Woven fabric dates from 25,000 BC (Germany). Colorants used by Cro-Magnon in decorating caves were most likely also used as makeup. Baskets derive from cording, and can be made waterproof by lining them with leather-hard clay. That is one step away from fired pottery.

[\[return to text\]](#)

Note 13 --

The "migration" of Cro-Magnon into Europe, or anywhere else, has not been firmly established, in that, for example, the expanded lithic industry does not start at some one location to spread out from there. Different aspects of the "cultural package" of the Cro-Magnon appear at diverse locations, representing, as James Shreeve writes in *The Neanderthal Enigma* (1995), "a complicated mosaic of mini-explosions that resemble one big explosion only when you stand back and take a long look at the whole."

This becomes an argument against the biological genesis of language, if we at least can accept that the use of language lies at the base of the cultural explosion in the Upper Paleolithic, for it would assume that humans all over the planet "evolved" nearly simultaneously. Of course a thousand-year lag looks instantaneous from our perspective.

[\[return to text\]](#)

Note 14 --

This presumes that North America was invaded from Northern Asia. But it is clear that most of North America was populated from South America via the Caribbean, originally some 30,000 years ago, and again after 9000 BC. The west coast regions may indeed have been populated from Asia also after that date. We have no records, since the general rise of the oceans after the glaciers melted has destroyed evidence of coastal settlements.

[\[return to text\]](#)

Note 15 --

"In our own modern conceptual world, the opposite seems to be self-evident: we look into the future, while the past lies behind us. Continuing with this line of thought, we might say that while we proceed along a temporal axis "headed towards the future," the Mesopotamians, although they also moved on a temporal axis in the direction of the future, did so with their gaze directed towards the past. The Mesopotamians proceeded, so to speak, "with their backs forward," that is, facing backwards into the future."

-- From Stefan Maul *Die altorientalische Hauptstadt -- Abbild und Nabel der Welt* (1997) translated by Thomas Lampert

See also Nicholas Osler, *Empires of the Word* (2005), for more details on Sumerian, as determined from Akkadian sources.

[\[return to text\]](#)

Note 16 --

Do not confuse the insistence of the *Annals of Shu* on the existence of Yao and Shun with "legend," for they are not identified as "Emperors" (or "legendary emperors" as western commentators would have it), but are clearly identified as "Gods" -- a perfectly legitimate term for the two planetary apparitions. See James Legge, translator of *The Sacred Books of the East, The Shu* (volume 3) (1879). Legge's translation and notes still stand as a classic.

[\[return to text\]](#)

Note 17 --

The Mesoamerican *Annals of Cuahitlan* claims we are living in the 5th age with no reference to the start of the current age. The first four ages are 676, 364, 312, and 52 years long. We could place the end of the 4th age in 1440 BC. That places the first creation in 2896 BC, or about 200 years after 3100 BC, and about a hundred years later than the recovery period for other people after the world flood. Interestingly, the first age ends in 2168 -- about the time of the demise of the Old Kingdom of Egypt.

This may be coincidence, however, since the ages are obviously numerologically constructed and based on the later importance of the numbers 52 and 13.

[\[return to text\]](#)

Note 18 --

Ralph L. Roys, in *The Book Of Chilam Balam of Chumayel* (1933) writes:

"A Katun of the same name recurred after approximately 256 years, consequently at the end of that time history was expected to repeat itself. The events recounted in the Maya Chronicles found in the Mani, Tizimin and Chumayel manuscripts [The Books of the Chilam Balam] offer excellent grounds for believing that this belief was so strong at times as to actually influence the course of history. A surprisingly large proportion of the important upheavals in Maya history appear to have occurred in some Katun named either 4 Ahau or 8 Ahau."

In a footnote he adds:

"Katun 8 Ahau recurred approximately every 256 years, and for a thousand years every time a Katun of this name occurred, the Itzá were driven from their homes, no matter where they were living at the time. Late in the Seventh Century A.D. they were expelled from Chichen Itzá after their first occupation of that city. In the middle of the Ninth Century they were driven out of Chakanputun. At the end of the Twelfth Century they were again driven from Chichen Itza by Hunac Ceel. About the middle of the Fifteenth Century Mayapan was sacked and destroyed; and strangely enough it was again in a Katun 8 Ahau at the end of the Seventeenth Century that the Spaniards conquered the last Itza stronghold at Tayasal, which was the end of this remarkable nation."

Schele and Freidel (in *A Forest of Kings*) similarly relate, about the meek acceptance of Christianity by Can-Elk, the last of the Maya kings, in AD 1697:

"This fatalism was part of the legacy of the Classic-period attitude toward history and its relationship to cyclic time and supernatural causality. Classic-period scribes emphasized the connectedness among the actions of their living kings, the actions of their ancestors in the historical and legendary past, and the actions of gods in the mythological past. ... The result of this type of thinking, transformed by the exigencies of the Collapse and then the Conquest, became predictive history.

Note 19 --

The 52-year interval after 2349 BC was in solar years, which were "Tun years" in the records of the past. The interval after 1492 BC was also 52 "Tun years" on the Tzolkin calendar, but represented an interval of 50 solar years. See Appendix B, "The Celestial Mechanics," the "52-year cycle." I discuss the Mesoamerican calendar in the chapter "The Maya Calendar."

Note 20 --

Most of our memories are constructed, or rather reconstructed, by us if they involve action, for we fill them out with the appropriate details, to the point of making up dialogues. Which is why memories reported as evidence in courts are suspect. Of course we do have other memories too. You will probably remember the layout of your house at age three, even though you do not remember a single event or action from that age. All animals are capable of memories involving the geography of their environment, and often with astounding accuracy.

Note 21 --

The shift of attention is managed by the "reticular formation" (Jaynes) or the "amygdala" (Goleman) or some other primitive element located at the base of the brain, with connections to sensory and motor areas of the brain and the spinal cord, which has the purpose of awakening certain parts of the nervous system while suppressing others on sensing external stimulations which require attention. How this is judged is beyond me.

Note 22 --

Hollis Frampton, in *Circles of Confusion* (1983), reports on the interview of the holder of the world's land speed record at Bonneville Salt Flats, Craig Breedlove, after he had lost his brakes and parachutes at the end of a test run -- flying off the end of the course at 620 miles per hour (1000 km per hour).

"The car went out of control, sheared off a number of telephone poles, topped a small rise, turned upside down, flew through the air, and landed in a salt pond."

Breedlove survived without a scratch. Frampton listened to a taped interview started immediately after the wreck, and wrote:

"Breedlove delivers a connected account of what he thought and did during a period of 8.7 seconds. In the course of the interview, Breedlove everywhere gives evidence of

condensing, of curtailing; not wishing to bore anyone, he is doing his polite best to make a long story short."

Frampton notes that the tape ran one hour and 35 minutes, a 650 fold expansion of experienced time.

A similar incident is recollected by Walter Shapiro, in "The Washington Post Magazine" (November 9, 1980), about a Navy test pilot, Major Russ Stromberg, whose plane lost power on takeoff from an aircraft carrier. In 8 seconds before ejecting he tested the controls, judged the consequences, and determined when to eject without either landing on the deck or at the site of the crash. It took him 45 minutes to describe the 8 seconds. (cited by Edward T. Hall, in *The Dance of Life*, 1983.)

Note 23 --

There is obviously more to learning "what others might be thinking" than what is suggested here. Sarah Blaffer Hrdy writes:

"The reason our species has managed to survive and proliferate to the extent that 6 billion people currently occupy the planet has to do with how readily we can learn to cooperate when we want to. And our capacity for empathy is one of the things that made us good at doing that."

"Predators from gopher snakes to lions have to be able to anticipate where their quarry will dart. Chimps and gorillas can figure out what another individual is likely to know or not know. But compared with that of humans, this capacity to entertain the psychological perspective of other individuals is crude."

-- "Mothers and Others," *Natural History* (2001).

Note 29 --

I am more inclined to view the *Iliad* as fiction purposely crafted "in the style of" an earlier period or a lost earlier literature, or possibly carried forward from a remote time, not as history, which is a substrate added over time, but as a tragedy. The *Iliad* spans only some two months, and is not about a war, but about the effects of the anger of Achilles and his reluctance to initiate action.

There is no archaeological evidence for an extended war at Troy and the city has not been located or identified. The hill at Hisarlik is too small to serve as the citadel of Troy, it is not in sight of the sea, and was repeatedly destroyed by natural disasters, and at the wrong times. But by the sixth century BC, as the Asiatic Greeks faced their defeat by the Persians, the *Iliad* became the favored epic of the heroic forebears of the conquered Greeks. Everyone believed that the war had happened. Greeks on both sides of the Aegean traced their lineage to

the heroes of the *Iliad*.

There is not a single mention of texts in the *Iliad*, even though these were already in wide use in Mycenaean Greece (supposedly by 1200 BC, and certainly by 900 BC). The tradition in antiquity, that Homer was blind and therefore could not write, points to a purposeful falsification also, and lends an aura of authenticity to the epic.

But the final composition of the *Iliad* has to be placed in the 7th century BC when the Greeks possess an alphabet. The poem selectively picks details from an imagined past. The battle tactics are wrong, as is the armor, and the funeral customs are foreign. There are anachronistic references to the Olympic Games, and the Gods are mocked -- suggesting a composition after perhaps 650 BC.

If the *Iliad* had achieved status as a classic at an earlier time, the vocabulary should have been recognized as archaic by the Greeks of the third century BC, since language conforms to classics. Alfred de Grazia suggests that the "heroic diction" was a purposeful amalgam of dialects of a late date.

Jaynes also forgets (perhaps) that events which are discussed and recounted will be remembered. This is true for early childhood experiences, and ought to be true of pre-subjectively conscious people also. Jaynes places the *Iliad* too close in time to his date for the change to *subjective consciousness*, and thus has to conduct an argument from an indefensible position.

It is quite possible that the whole of the *Iliad* (as Talbott has claimed) is but a retelling of the "War of the Gods" of 3147 BC. It strikes me, also, as a purposeful creation -- in a purposeful "antique style." If so, it is all the more marvelous that the *Iliad* passed through Jaynes's analysis transparently.

What we are seeing perhaps is the embellishment of memory on a grand scale, although the rigidity of the underlying structure of the *Iliad* argues for a conscious composition. But the *Iliad* was also extensively edited and codified after about 600 BC by others.

The *Iliad* was written with clear intent, as was certainly understood since the 19th century AD by literary critics -- Guy Davenport in 1954 wrote, "Not a line ... can be put out of its place" -- and with a clear political balance between the egos of the Asiatic and the European Greeks. But the facts of a detailed fiction along with an adopted diction has little to do with Jaynes's analysis, which deals with the use of body-part nouns for feelings and emotions and the actions initiated by the Gods. There is no need to consider the historical dimensions of the *Iliad*. Jaynes makes this clear in the closing paragraphs of his investigations of the *Iliad*, and I certainly agree with his conclusions.

In *Collapse* (2005), Jared Diamond writes about communal decision making in the highland communities of New Guinea, still in practice after the arrival of Dutch and Australian colonial government in the 1930s:

"Decisions were (and often still are today) reached by means of everyone in the village sitting down together and talking, and talking, and talking."

And, he notes, this happens today to the extreme frustration of New Guinea government officials. As I note elsewhere, the same process of reaching complete consensus through endless talk was used by the much larger groups of Plains Indians, in the 19th century AD, to the frustration of US treaty negotiators.

Note 31 --

How can Steven Pinker, popular author of books on language, all based on the notion that language is an inherent function of the brain, evolved over millions of years, be so wrong? (*The Language Instinct* (1994) and other books.) My first clue was his complete misunderstanding of "baby talk." He understands it as functional. I understand it as a completely disinterested attempt to communicate with children. I finally verified what I soon suspected, that Pinker has no children and has thus never had the opportunity to closely observe children in the acquisition of language abilities over extended periods of time.

[\[return to text\]](#)

Note 32 --

But note that, despite the shorthand of this statement, what we are talking about is *subjective consciousness*, not *self-consciousness*. I have seen people dismiss Jaynes by noting that chimps show signs of self-consciousness. Well, so do my dogs. Animals certainly know who they are and are able to reflect on themselves. But no chimp has ever escaped a zoo. That would require a measure of *subjective consciousness*.

Added note: In 2006, a chimp escaped from a zoo in the US.

The Maya Calendar

The Mesoamerican / Maya calendar contains cycles within cycles, all of which are held as significant to some degree in determining the "quality" of any day in time. Many of the cyclical features look like remnants of earlier calendar systems which could not be discarded, but were carried forward in time as each change in the calendar was forced upon the users with a change in the structure of the Solar System. I would thus suggest that the current calendar -- because of its inclusion of these arcane, and in some cases near-useless, features -- shows faithful and careful adjustments to changes in the number of days in the year over a very long period. I'll suggest, in fact, that the current calendar can certainly be traced back to the era starting in 3147 BC, and likely a prior tally used solar years before 3147 BC. I think this is clearly shown by the remnants retained at later times. In fact, a page of the *Chilam Balam*, which deals with the events of 2349 BC, specifically states, "And then days of the year were introduced." But this is the addition of a round of 13 numbers superimposed on the original "monthly" calendar of 20 named days.

- The initial period when the southern plasmoids showed up started in 10,900 BC.
- In 8347 BC, as the 13th Baktun (400 year periods) on the ongoing yearly calendar was completed, the first era of the plasmoids came to a close, and a new count was started, at least of Baktuns, Katuns, and Tuns. 2553 solar years had lapsed since 10,900 BC.
- The fact that 13 Baktuns were completed was long remembered. In fact two of the inscribed Long Count series of glyphs are counted from this date when the earlier period ended in 8347 BC. (At the Temple of the Cross at Palenque, and at Stela C at Quirigua. So says Sylvanus Morley in the 1915 Smithsonian Institution Bulletin 57 of the Bureau of American Ethnology, *An Introduction to the Study of Maya Hieroglyphs*. J. E. Thompson confirmed this in 1950.)
- In 3147 BC, by coincidence, again as a 13th Baktun on the ongoing calendar was

completed, the "Era of the Gods" came to an end. A new count was started of Baktuns, Katuns, and Tuns. This time a rotation of days was instituted, amounting to a rotation of 20 named days. These repeated 12 times to account for the 240 days of the year. The 12 may have rotated at the same time as the 20 named days.

- In 2349 BC this was augmented with a rotation of one extra day, a total of 13 numbered days (which also represent a half period of the Moon) simultaneously with the 20 named days. This is called the "Tzolkin," and consists of a total of 260 distinctly identified days (named and numbered) before repeating again, and exactly filling the year of 260 days.
- In 1492 BC another calendar was introduced, called the "Haab," consisting of 20 numbered days rotating through 18 named "months," which totaled 360 days.
- The Haab was adjusted in 747 BC to add 5 extra days (a short month), so that the calendar then totaled 365 days.
- An accurate count of days was also established in 747 BC, with a system called the "Long Count." The Long Count tallied days, "months" of 20 days, years (called "Tuns") of 360 days (not 365), double decades of 20 Tuns (called "Katuns"), and a measure of 400 years, called simply "400," or, in the nomenclature of archaeologists, "Baktuns."

It is also certain that there was a calendar, in the sense of a count of years, going forward from (the retrocalculated year of) 3114 BC, since the Maya *Chilam Balam* correctly places the earliest event of the current era in the properly named double-decade Katuns.

Also, some count of years, or spans of time, was recorded since circa 41,000 bp. One of the pages of the *Chilam Balam* specifically deals with this.

I should also note that the Baktuns and Katuns were probably in use by 10,900 BC, for the *Chilam Balam* has reference to this in Book 11 which details (what we would call the start of) the "first creation" of 10,900 BC. In 8347 BC, with the end to a period of about 2500 years of the southern ball plasmoids, the count of years had reached 13 Baktuns, and the year tally was reset to zero.

It happened again in 3147 BC, with the collapse of the "Era of the Gods," that 13 Baktuns were reached. Thus in 3147 BC the Baktun measure of the calendar was again reset to zero. This marks the termination of the "Second Creation" of the Olmec and Maya, marked especially since it was accompanied by the worldwide flood. Meanwhile, Saturn had started to blaze in 4077 BC.

Note that the "Creations" are not clear-cut episodes separated by definitive collapses of celestial conditions. For example, the date of 4077 BC, when Saturn blazed up in a nova expulsion, is not accounted for. It makes one suspect that the whole idea of various numbered creations might be a constructed effort of a late date.

[Image: August 13, 3114 BC, day "zero" of the Maya calendar. This reads, "13 Baktun, 0 Katun, 0 Tun, 0 Uinal, 0 Kin, 4-Ahau 8-Cumku, was seen the image." After research.famsi.org.]

... preliminary observations

With the institution of the Long Count in 747 BC, the Olmecs were able to calculate backwards into the past to determine the exact names and numbers of the days on the Tzolkin calendar and Haab calendar. When the completion of the previous era was reached in 3147 BC (which they and we calculate as 3114 BC) -- the Tzolkin day was 4-Ahau and the Haab day was 8-Cumku. The Peten region Maya were very proud of this feat of retrocalculation and had reference to it constantly in their standing stone monuments.

As interpreted by archaeologists, the Long Count used August 11, 3114 BC, on an equivalent Gregorian calendar as a starting point. Because there is a two-day difference in calendars between early Olmec (and current Guatemala) and the calendar of the Maya (and Aztecs), the other widely accepted date is August 13, 3114 BC. In both cases it is assumed that the year has always been the same length as today -- 365.2422 days. The Classical era Maya (AD 400 to 700) also used this measure, arrived at independently, to suggest a series of days which never varied, and retrocalculate the Tzolkin and Haab day names and numbers at the beginning of the current creation -- even though they are incorrect. There were records involved in the recall of history, but they were not accurate.

The archaeological count of days (which match the Maya Long Count against our own erroneous string of calendar days) starts at August 11, 3114 BC. This was first derived by Joseph Goodman in 1905. Juan Hernández in 1926 came up with a calculation of August 12, which was followed in 1927 by John E. Thompson's calculation of August 13. In 1935 Thompson revised his calculation to August 11. As the dean of Maya archaeologists, Thompson's estimate is generally used today, although any number of researchers think that the date of August 13, 3114 BC, is more likely to be correct.

"Overwhelming support for the precise placement of the Thompson [August 11] correlation number came in the 40's and 50's, when newly discovered calendar counts still being followed among the Quiche, Kekchi and Ixil of Guatemala all supported the [August 11 date]."

-- John Major Jenkins at fourahau2.htm.

The above "correlation dates" are on the equivalent Gregorian calendar, converted from a measure known as the "count of Julian days" used by astronomers since the 16th century AD. The "astronomical year" for 3114 BC is -3113, based on recognizing a "year zero." The Gregorian calendar will match solar years under the assumption that the length of the year has not changed.

The Julian calendar, in use from about 40 BC to about AD 1500, and not to be confused with "Julian days," is based on a year of 365.25 days, and thus the Julian year is slightly longer

than the Gregorian year of 365.24 days. By 3114 BC the Julian calendar places dates about 13 months (numerically) further into the past than the Gregorian calendar.

There have been suggestions that the Maya made a two-day correction at some time in the past, and that this accounts for the difference of two days between the Long Count notation found on monuments in antiquity, and in the continued use of the earlier Tzolkin among contemporary tribes.

In fact, Vincent H. Malmstrom, writing in *Cycles of the Sun, Mysteries of the Moon* (1997), suggests that this happened in circa 48 BC -- that the Maya in effect skipped two days, thus setting the calendar ahead by two days. Malmstrom sets out when and where this would have happened, and the reasoning behind the change, but admits that his "story" is pure conjecture.

A "correction" carries with it the suggestion of an absolute and uniform use of the Tzolkin and Haab calendars by many tribes spread over a large area since remote antiquity. The concept of uniform agreement doesn't work among humans. I think it should be considered that by 747 BC, when the Long Count was devised, there were already some diverse regional opinions on the concept of when one era ended and another started -- a question about the existence ("completion") of two days which had not been seen in progress. Considering that the 2000-year-old Tzolkin was in use among many diverse tribes, it is likely that some stubborn local opinions prevailed. But there might be other reasons, too.

The "August 11" calendar reaches further into the past by two days. It correctly fits the start of the Long Count on February 28, 747 BC, and accounts for later retrocalculations of some past events by the Olmecs. But it was supplanted by the "August 13" calendar because the "August 13" calendar "correctly" fit what was thought to be the quality of a number of important dates in the year 685 BC, and in 1492 BC. (Discussed in the chapter "The Day of Kan.")

My sense is that in the Valley of Mexico, and perhaps also in the Olmec coastal region, the "August 11" calendar was replaced by the "August 13" calendar by 400 BC, but long after the use of the "August 11" calendar had been exported and adapted by tribes in Southern Mexico and Guatemala, where it has been retained in the same form to today. (Some researchers have suggested that the calendars may have started in Guatemala.)

It should also be pointed out that August 11, 3114 BC (or August 13), is not the start of the current era, but is the end (the completion) of the previous era. The texts at Palenque, for example, make this clear when it is read:

"And then the past epoch ended. On 4-Ahau 8-Cumku [presumed to be August 13, 3114 BC], 13 Baktuns were completed."

The transliterated text reads:

"(And then) there was an event / (on) 4-Ahau / 8-Cumku / were completed / 13 Baktuns"

There can be little doubt, no matter how it is translated, that this phrasing speaks to the completion of a previous 13 Baktuns -- 5200 solar years. It points directly to an earlier calendar which would have started in 8347 BC. Occasional stelae specify the placement on the day 4-Ahau 8-Cumku of "the three stones" or alternately the first "image of the turtle." The references here are to a day in the year 3147 BC, but the day name and number are known only because of a retrocalculation by the Olmecs or the people of the Valley of Mexico in antiquity, probably after 600 BC, which found this day name and number for the restart of the calendar in 3147 BC, even if incorrect. It is, in fact, incorrect since the three stones or the turtle were seen to be placed in 10,900 BC.

Support for a correlation based on the date of August 13 (for the year 3114 BC) comes from the record of eclipses, which cannot be off by a day. My observation is that the starting date of February 28th, 747 BC, Gregorian, corresponding to the Long Count date of 6.0.0.0.0, can only be upheld with an "August 11" correlation. This matches the start of the Era of Nabonassar in the Eastern Mediterranean region (the evening of February 27, 747 BC) and the start of the Roman calendar (the day after February 28th). I think the arguments among archaeologists and historians may be meaningless. It should be recognized that there were two Long Counts in use, and that they differed by two days. [\[note 1\]](#)

The first Tzolkin date inscription was in use at the Zapotec site of San José Mogote in the Oaxaca region in about 600 BC. By 400 BC the Tzolkin and Haab calendars were in use at Monte Alban in Oaxaca.

In 1939 the earliest engraved Olmec Long Count was discovered and depicted on Stela C from Tres Zapotes as 32 BC (Julian). Malmstrom notes that this stele celebrated a total eclipse of the Sun as it rose out of the Eastern Gulf of Mexico, if the August 13 Thompson correlation is used. Otherwise it would be off by two days. Malmstrom notes a transcription error in the stele (carving three bars rather than two to accompany the three dots for the "kin") and then writes about the eclipse:

"... whose path ... passed right over the Olmec ceremonial center of Tres Zapotes at dawn on the morning of August 31, 32 B.C. A more frightening celestial event can scarcely be imagined, for the sun rose out of the Gulf of Mexico totally black except for a ring of light around its outer edges. [It was] described as an annular, or ringlike, eclipse, and subsequent calculations at the U.S. Naval Observatory have revealed that the disk of the sun was 93 percent obscured (personal communication). Surely, a 'day without a sunrise' is not likely to have gone unrecorded by the Olmecs!"

He concludes with:

"... therefore, the inscription of Stela C, erroneous though it seems to be, appears to confirm the accuracy of the original Thompson correlation value [August 13] between

the Olmec calendar and our own."

Malmstrom also identifies a much later eclipse seen at Copan (Copán) on June 29, AD 763 (9.16.12.5.17 6-Caban 10-Mol), and suggests that it had been predicted. Again, the date agrees with a lunar eclipse only if the "August 13" correlation is used. The date was recorded on a half dozen stelae. Archaeologists have not as yet accepted this. (Surprise!)

It should be obvious also from many inscribed stelae that it is the completion of a time period that is celebrated, not the start. The event of 3114 BC (actually 3147 BC) is known as the end of the "second creation," which is inferred from the fact that the event which we know as the "flood of Noah" is consistently called the (completion of the) "third creation." The reason the "second creation" of 3114 BC ended with the completion of 13 Baktuns (the count of years then went to zero Baktuns), is that the predecessors of the Olmecs had already been counting years (solar years) from much earlier than 10,900 BC. In 8347 BC 13 Baktuns had been reached.

In that the Sumerians managed to have a count of years (in days) from 4077 BC, it is reasonable to suggest that the Olmecs or their predecessors were also perfectly capable of this. "Counting," after all, must have been one of the high sciences even for the slightly more remote Cro-Magnons.

The Beginning of Time

The phrase of "the image" is completed by some stelae as "the image of the turtle." As a turtle this would represent the appearance of the southern plasmoids, actually, the last appearance -- the completion of this event. We could most likely place the first showing of Peratt's southern plasmoids in 10,900 BC, the year of the first contact with Saturn at the start of the Younger Dryas which destroyed North America.

It has always been strange to note that the "zero" number for the Baktun at the start of the current era (the Maya retrocalculated 3114 BC, although actually 3147 BC) actually has a value of 13 Baktuns. Also, the date of the start of the "first creation" is not the nova event of Saturn in 4077 BC, which the *Popol Vuh* describes as the "dawning of the light," but an event 4000 years earlier -- the last instance of the showing of the southern ball plasmoid.

Here are the four creation periods:

- 8347 BC, end of the first creation
- 3147 BC, end of the second creation
- 2349 BC, end of the third creation
- 1492 BC, end of the fourth creation

The last period is questionable, it might not be over yet.

In the iconography of the Maya, the "turtle," which appeared in 10,900 BC, at the start of the "first creation," is often combined with the appearance of Jupiter ("Hun-Nal-Ye") as the "First Father" in 2349 BC, at the end of the "third creation." Just like the second and third southern plasmoids would seem to have appeared out of the carapace of the "First Turtle" soon after 10,900 BC, so First Father is shown to rise out of a turtle carapace in 2349 BC, assisted by Hunahpu and Xbalanque (from the era of the 7th century BC, no less). This scene is repeatedly shown on bowls and vases. And this is how the mythological history of the Maya advanced.

In *Maya Cosmos* Freidel and Schele present the imagery of a painted pot showing six Gods in council with a elderly seventh God. The council is urging the seventh god to "bring into existence" and "put in order" the place called "black is its center" -- a fit description of the deep shadow at the center of the Absu which changed size and shape over the year. It suggests that the dark doorway of the Absu was hiding something.

The elder God (God L) of the painted pot is easily identified as Jupiter as well as First Father. The six Gods have various names, of which some are easily identified. God "Three Born Together" is obviously the three plasmoids of the south and God "Nine Footsteps" is Mars. Subtracting God "Three Born Together" of the south leaves five Gods all associated with the polar configuration of the north. This is the same number as listed in the *Popol Vuh* (see the chapter "The Popol Vuh" for details). These are Uranus, Neptune, Saturn, Mercury, and Mars, all of which were easily distinguished in the earliest time after 9500 BC, although some disappeared behind (or above) each other by 5800 BC. And Mercury is misnamed for Venus, which probably did not exist as early as this council is meant to depict. God L (Jupiter) is here distinguished from the polar configuration planets, and it is a rare insight to suggest that indeed at the time of the council, sometime before 8347 BC, Jupiter had been known and seen for eons, and therefore was properly represented as very old.

This illustrated pot also points up the Mesoamerican concept of the simultaneity of time. The council of the six Gods happens after the start of the "first creation" period after 10,900 BC as told by the *Popol Vuh*, resulting eventually in the creation of the Sun -- the lighting up of Saturn. But the disposition of the dark spot -- the cleft -- in the Absu, in fact the whole of the Absu, is not tackled until the end of the "third creation" of 2349 BC. Most of the six Gods had long since disappeared from view by then. Archaeologists today think that the "dark spot" is a dark area of the cloud of stars of the Milky Way.

The other (and more common) image which is often represented as first appearing on 4-Ahau 8-Cumku, is the setting of the three hearthstones in the sky. These have been identified by Schele as a star of the belt of Orion and two of his feet (Alnitac, Rigel, and Saiph). The cluster M-42 is enclosed in this triangle, like a fire at the center of a three-stone hearth. The constellation is below (slightly east) of the intersection of the equatorial and ecliptic, and removed from the brightness of the Milky Way. In fact, these stars first showed up in 2349 BC, the date of the end of the "third creation," at a location known as "Lying-down-Sky" which must represent the gap in the Absu during the equinoxes. Other names for the shadow

gap in the Absu are the "Earth Partition," "Black is the Center," and "Cleft Sky" -- the name for Yaxchilan. Where the Earth shadow fell on the Absu, no stars would have been seen in the dark area (excepting a few very bright stars).

Since the skies have been invariant since even before 10,900 BC the three hearthstones could not refer to the end of the second creation ending in 3147 BC, but to the first creation ending in 8347 BC. As stars, these three stones were not placed; they were always there, although not seen until some time after 2349 BC. This would suggest to me that the "setting of the three stones" probably refers back to the "first creation" when the three southern plasmoids appeared in the south -- set beneath the "mighty stone" (Saturn) of the north, as the *Chilam Balam* relates in Book 11.

The date of 3147 BC is actually a reasonable estimate for the start of the near-current era, that is, as the date for the close of the "Era of the Gods" and the end of the second 13 Baktun cycle of sets of 400 years (5200 years). The Olmecs must have had a record of the number of solar years which had lapsed since various worldwide events, and were certainly able to place events in named year tallies after 3147 BC. The records of the *Chilam Balam* books of the colonial-period Maya are accurate to the Katun (20-Tun period) after 3147 BC, allowing for some slight-of-hand by the 16th-century-AD Maya scribes, who made some unwarranted "corrections" to the chronology.

Time spans between "ages" (after 3147 BC) show up in later Mesoamerican legendary histories and are correct or nearly correct, and match the records of other civilizations. No clear record of events or time spans shows up among the sparse Mesoamerican records of the much earlier period before 3147 BC, except as might be inferred from their calendar measures.

When the Long Count was established in 747 BC by the Olmecs, they added six Baktuns (2400 Tun years) to a starting calendar date of 0.0.0.0, based on the assumption that the year (the Tun) had always consisted of 360 days. This was correct at that time, because the year had indeed consisted of 360 days since the establishment of earliest Olmec ceremonial center after 1500 BC (San Lorenzo). Thus the Olmecs also removed from the Long Count calculation the five-day correction that was added to the annual Haab calendar in 747 BC -- the "years" in the Long Count are based entirely on the earlier 360-day intervals, not on 365-day intervals. The rather arbitrary addition of 2400 Tuns (six Baktuns of 400-Tun years) to the Long Count would bring the actual "zero" date to 3147 BC, off from the archaeologically and Classic Maya retrocalculated date of 3114 BC year by 34 years. [\[note 2\]](#)

A "Tun" is a year. Before 3147 BC (the thousand years of the "Era of the Gods" and the 4000 years before that) the Tun was 225 days (I have assumed). After 3147 BC (the worldwide flood) the Tun was 240 days. After 2349 BC (the "flood of Noah") the Tun was 260 days. After 2193 BC (the fall of Akkad and the Old Kingdom) the Tun was 273 days. After 1492 (the Exodus and the fall of the Middle Kingdom) the Tun was 360 days -- and at this value it remained in its Long Count use, even though 5 additional days were added to the year after

747 BC when the year changed to its current value. Although the earlier "years" were shorter, the effect of adding 2400 Tuns (6 Baktun) was to have a calendar which reflected solar years, and is thus nearly identical to the accepted (scientific) chronology -- which assumes that all years in the past were Gregorian years of 365.2422 days.

When researchers calculate backwards to 3114 BC, using an actual count of days, they use a 365.2422-day Gregorian year. The researchers and archaeologists thus end up being able to place events in certain "years" which will match the intent of the Olmec and Maya Long Counts. Both are in error in terms of the actual number of days before 747 BC, but both are nearly correct in terms of "years" if these represented solar years. Both are in error because the later Maya also ignored the fact that the Olmecs knew the length of the year had been 360 days prior to 747 BC, and, in fact, designed the Long Count to tally in 360-day Tuns, not 365-day Haab years.

I have no problem with the suggestion that history might have been remembered from long before 3147 BC, or that some aspects of the Mesoamerican calendar date back to 2349 BC, and the count of years dates from before 10,900 BC. After all, in Northern Mesopotamia people had been accounting for trade products since about 8000 BC, and kept track of the number of days since 4077 BC. [\[note 3\]](#)

Mesoamerican iconography seems to spring to life sometime around 1500 to 1200 BC without any sign of a developmental phase. These are the dates of the first images carved in stone or engraved on celts. This suggests that the stone carvings were preceded by a long period of works in wood and other perishable materials, a period possibly lasting thousands of years. As an example of how long records could last, note that the *Dresden Codex*, a book on plaster-coated tree bark, was transcribed in about AD 1200 from material dating to before AD 700. It was sent to Spain after AD 1550. Such long endurance of books suggests the possibility of other records dating from more remote antiquity -- including, of course, chronological records.

Over the following few paragraphs I will speculate about possible early calendars, although after 2349 BC the use of a day and month calendar is certain. In circa 2350 BC Yao, the first "emperor" of China corrects the calendar. In the *Enuma Elish*, dating from Babylon sometime after 2000 BC, but detailing events in 2349 BC, the God Marduk does the same. Both of these instances assume there was an earlier calendar.

The First Calendar

I have estimated that before 3147 BC the year was 225 days long (see Appendix A, "Notes on Chronology"). A very simple but sophisticated calendar system could have been in use: the year was divided into 9 groups of 25. Fingers of one hand could be used to count up to 4. When 5 was reached the other hand closes a finger -- representing 5. Thus the other hand could hold a total of 25 units. The "Nine Lords of the Night" rotated nine times through the

sets of 25 to count to a total of 225 days.

I am using the five fingers because both Olmec and Mayan ciphers were represented in base 5. The "Nine Lords of the Night" were still being counted 5000 years later, and still rotated endlessly through nine names. [\[note 4\]](#)

The "Nine Lords of the Night" together with the 25 "day numbers" (or more likely "day names") would produce 225 unique names for the days of the year. This sort of system would constitute a calendar which might have been a model for the later Tzolkin, which rotated 13 numbers against 20 names.

Who the "Nine Lords of the Night" were, or what they represented at the time before 3147 BC, is unknown. I suspect, on the basis of other sources, that the "Nine Lords of the Night" represented Jupiter and the eight nearest satellites, visible at close range after 3147 BC. Jupiter was known as "The Nine." See the chapter "The Chilam Balam" for this.

The "Nine Lords" might also represent an assignment of nine gods to the nine rings of the Absu -- the House of Nine Bushes. These would show at night (and not likely be very bright during the day).

left hand: 1 through 4
right hand: 5 through 25
9 Lords of the night (9 x 25 = 225 days)

An Intermediate Calendar

Of course, the previous is speculation. But for the period after 3147 BC, we can be much more certain of a calendar. After 3147 BC the year was (I suspect) 240 days long. The 240 days could be counted as multiples of 20 and could be made to fit 240 if 12 sets of 20 were to be used. A lunar calendar might be suggested for this era, with the period of the Moon at 20 days, but there was as yet no Moon. There is not a single suggestion of lunar calendars anywhere in the world before 2349 BC. It is more likely that the 20-day periods represented agricultural periods. It is possible that the 20 "day names" were rotated against 12 "day numbers" -- which would give 240 unique date-names to the year. [\[note 5\]](#)

The Mayan word for the 20 days is "uinal" which translates as "moon" and means "month." It also means "person," since a count of 20 day names could be understood as addressing all a person's fingers and toes. This person became personified as a "time-lord" who brought in the month as a parcel. Because of some such metaphorical construction, the continuity of time for Mesoamerican people was never a certainty (as it is for us) -- the bearer of time might not arrive with his burden.

The "Nine Lords of the Night" -- whatever their value might be -- remained in use.

The Tzolkin Calendar

After 2349 BC the year went to 260 days. At this point speculation stops, although I have reached a year length of 260 days by somewhat of a circular argument (in Appendix A, "Notes on Chronology"). A line of a page of the *Books of the Chilam Balam*, dealing with the events of 2349 BC, reads:

"And then days of the year were introduced."

There certainly was a calendar in use, dating back some 3700 years, as the *Books of the Chilam Balam* show. This calendar consisted of a rotation through twenty named days. Only the preexistence of the twenty named days makes sense in the subsequent introduction of the Tzolkin calendar.

The count of days, the 260-day calendar known as the Tzolkin, as instituted in 2349 BC, was a lunar calendar. The Moon was intercepted in or after 2349 BC (see the chapter "The Day of the Dead"), and was probably in a stable orbit within a few years. Mesoamerica started to rotate 13 new "day numbers" against the existing 20 "day names" to yield 260 uniquely named days constituting a year. Brilliant! Every day of the year was individually identified and each was different from the others.

[Image: 20 Day Names of the Tzolkin Calendar. After Linda Schele and David Freidel "A Forest of Kings" (1990).]

It is unlikely that the period of the Moon was 20 days at this time, or that there were 13 months to the year. More likely the number 13 is a count of a half moon period -- from a new moon to a full moon, and back. Thus the period of the Moon was likely 26 days and there were 10 lunar months of 26 days in the year, and 20 half months of 13 days.

Typical of Mesoamerican thinking, it was the completion of a change to a full moon or the finish of the waning to a new moon that counted -- 13 days for each. Thousands of years later, the Maya still call the 20-day period a "month," and a "moon" -- but not the 13-day period. This actually seems strange if the Moon's period was 26 days.

Anyway, each of the twenty days of the Tzolkin "moon period" had a separate name -- Imix, Ik, Akbal, Kan, etc. The glyphs for the day-names are unique from other glyphs in that all twenty are graphically represented as figures of some sort within the frame of an escutcheon seated on three feet. Some of the glyphs have not been recognized, which probably speaks to their extreme antiquity, as does the whole of the arcane nature of this calendar system. Glyphs which are known include tropical plants and animals as the environment of the location where these names were first selected. It has been suggested that these escutcheons are equivalent to the Egyptian name-cartouche used for the names of pharaohs and Gods. The three feet below the frame have been identified as a rope knot (Morley). Thus the escutcheons date from 2860 BC, and can be equated to the "shen" form in Egypt.

This system of a day count which rotates endlessly through 260 number-name combinations is actually the best evidence that an earlier calendar had existed. If the Lords of the Night were kept in use since 3147 BC, then there was probably a similar pressure to retain the day names after they became obsolete because they had constituted the base of a previous calendar.

Today the Tzolkin (which is still in use) shows no concern with time as a linear progression, only as a repeating cycle. This is endemic to the Mesoamerican languages, which understand time in topological terms, rather than a linear and endless series. An "historical awareness" in terms of understanding time as a linear progression does not take hold for another 2000 years. Mayan words for time involve references to round things, circles, and cycles. The future is expressed as going from here to there, as if invoking geography. We do this also, mentally, but our geography of time is a single line with no beginning or end.

The Tzolkin calendar makes no sense to us, who are used to a completely different method of tallying days. But it fits in with the suggested earlier calendar which rotated the "Nine Lords of the Night" against day names. The strangest aspect of the Tzolkin is that the 13 numbers are rotated against the 20 names, rather than "numbering" each of the names in a sequence of 1 to 13. Perhaps stranger still is that any group of 20 are known as a "month," although this may be because of the design of the later Haab calendar.

The languages of Mesoamerican people did not use tense (serial time) in verbs, but only the sense of "on-going" and "completed." In this manner the cycling of 1-Imix, 2-Ik, and 3-Akbal makes some sense, because to count 1-Imix, 1-Ik, and 1-Akbal would leave the moon-period uncompleted until the 13th count was reached. Similarly 1-Imix, 2-Imix, etc., seems to repeat the Imix day pointlessly. The point was to reach 13, when the Moon would have become full, or new, and simultaneously keep up a rotation through the twenty day names, each of which attributes some quality to the particular day. The result, at any rate, was to have a calendar with 260 separate names for each day of the year.

A Person: 20 digits and toes (day names)
13 Day Numbers (20 x 13 = 260 days)
9 Lords of the Night

The question also occurs, why was this 260-day calendar kept in use when the length of the year and the period of the Moon changed one hundred and fifty years later in 2193 BC, and again in 1492 BC, and then in 747 BC? There could be a number of reasons, but primary is the fact that the Tzolkin calendar, and the later Haab calendar, do not function as we would imagine a calendar to function, that is, as a sequence of numbers which have a one-to-one correspondence to the sequence of days, and are discarded just as the days are irretrievable once they have moved into the past. The Tzolkin has a different function to a people whose language base does not include a strong sense of time as a path, but who do have a heightened sense of space and geography. In Mesoamerica, time had a spatial quality, and the Tzolkin functioned as a map to the domain of time.

I also think that the Tzolkin was kept for the same reason that the *I Ching* in China (dating from the Shang era or before) was never abandoned, even surviving the book burning of 213 BC. If the Maya or Olmec were at all like other people throughout the world, they would believe that all their fortunes and failures in life were predetermined. The only glimpse into the future was to "read" the qualities of each day, for like fate, each was different from any other (and Tzolkin/Haab day-name combinations do not repeat for 52 years). Using the Tzolkin as a guide to life was not unlike contemporaneous Chinese use of the *I Ching*, or Mesopotamian and Indian astrology. Even if the number of days in the year changed and a more rational calendar were to be adopted, the Tzolkin would have to remain in use without interruption.

Modification of the Tzolkin

After 2193 BC the year went to 270, 275, or 280 days. The Tzolkin could easily accommodate the 280-day year by adding an additional rotation of 20 days. I suspect, however, that the year changed to 273 days. By chance, the Tzolkin could also accommodate a year of 273 days, since it would only slip behind by a count of 13 days every year. [\[note 6\]](#)

That the calendar fell out of sync with the Solar year did not matter as long as the Tzolkin's

primary purpose was to determine the quality of the days of the year. Consider also that the rotation through the twenty day-names had already been in use for 800 years. Certainly, too, it was kept because it represented high science to the Olmecs.

This science of the Tzolkin was used in the control of the Gods and spiritual powers. Specifically it was eventually used to control the travels of the Sun. This theme resounds through all of the history of Mesoamerica, and was repeatedly proven in the future to be correct and effective.

I suspect another cycle which has come down to us, a count of 819 days assigned in rotation to each of the cardinal points, was added in this era. Researchers have been unable to make anything of this cycle, except to note that 819 is the product of 7, 9, and 13. The period of 819 days revolved through the four cardinal directions.

Linda Schele and David Freidel, in *A Forest of Kings* (1990), note that in Maya texts the God K (also identified as God G-II), who clearly is Mars, is associated with the four directions. We therefore need to look to Mars.

First, let's note that 819 days happens to be exactly three times the length of the year (273 days) at this time ($3 * 273 = 819$).

The orbital period of Mars was 720 days. This has been proposed by Donald W. Patten and Samuel R. Windsor, in *The Mars-Earth Wars* (1996), for the purpose of their model, and as related to the period before 747 BC. From my use of this orbital period value, it appears to be correct.

In the era of 3147 BC to 2349 BC, the synodic period of Mars would have been $(720 * 240) / (720 - 240) = 360$ days. Thus Mars would show up in the same location of the sky every three years of 240 days, $2 * 360 - 3 * 240 = 0$ (and once every year and a half). This three-fold repetition of the calendar year is, of course, also reflected in the mysterious 819 days, as already noted.

Let me suggest the following as a history of this: After 3067 BC (when Mars first started to appear near earth), with the year at 240 days, the reappearances of Mars were marked, correctly, at 3 intervals of the 240-day year, 720 days. This was the index of possible catastrophic interactions with Mars, which was good until about 2750 BC, after which Mars no longer was seen near Earth.

After 2349 BC, when the year went to 260 days, three of the 260-day periods were used instead, 780 days. This was incorrect and may have been useless in predicting catastrophes, but that did not matter, for Mars had disappeared from consideration some 400 years earlier, and by the end of the previous era it was probably no longer recalled why Mars had been assigned to one of the cardinal directions at intervals of three calendar years.

After 2193 BC the year went to 273 days. The assignment of Mars to the four cardinal directions was accomplished on a rotation of three years of 273 days, adding up to 819 days. Even if nothing happened, it did not matter. The interval of three years, tied to the four cardinal directions and the planet Mars, was a formal part of calendar computations, and had nothing to do with the close appearances of Mars.

The predictive value of the 819 day cycle was still correct when in 1935 BC Mars again made a series of destructive approaches. We could guess that, because of the circular nature of orbits, the interval was still 15 or 30 years, but of course years of 273 days. Mars would cruise close to Earth after every 5th interval of 819 days.

What then happened at 819-day intervals after that? It may have been kept at the value of 819 because in 1492 BC and 1442 BC a different planet, Venus, started interfering with Earth. The Mars cycle of 819 days remained unchanged. The next opportunity would have been in 1492 BC when the length of the year changed again. But no changes were made.

The Haab Calendar

After 1492 BC the year changed to 360 days, and the period of the Moon changed to 30 days. This is certain from many sources throughout the world. A solution would have been to add five additional sets of 20 "name day" rotations ("months") to the Tzolkin, or to add five more numbers (from 13 to 18). But this would have been completely unacceptable, for the Tzolkin had to remain as it was, and as it had been for 1500 years. To extend the count would have been equivalent to changing our 7-day week to 9 days.

The only solution was a parallel calendar of 360-day period. This was done by starting a rotation through the names of 18 "months" (Uinals) of 20 days each, called the "Haab." Seven hundred years later this was augmented with 5 more days. Now for the first time we see a calendar instituted which has a familiar sensibility, like the numbered days of our months. The 18 months were separately named, but only 20 days were assigned to each month. The glyphs for the months are completely different from the Tzolkin glyphs and have the characteristics of the later development of the written language. A number of them also simply translate to "first," "second," etc. But the "months" -- that is, the Uinals -- still were 20 days long as they were previously, and were called "months" -- that is, a word meaning "moon." [\[note 7\]](#)

[Image: The eighteen months of the Haab calendar plus the additional five-day period of the "sleep of the year," Uayeb. After Linda Schele and David Freidel "A Forest of Kings" (1990).]

The 20 day **numbers** were most likely modeled after the 20 day **names** of the Tzolkin. The 360-day calendar of 18 months of 20 days also makes no sense, since the actual (lunar) months were 30 days long, but it neatly filled the year, and every three calendar months (60 days) coincided with two rotations of the Moon.

The Tzolkin remained in use, arcane as it was, to determine the quality of any day, and determined the lot in life of a person named for a particular number-name day on which he was born.

The two calendars were entirely different, yet both were kept in use for 3000 years. (In some regions of Guatemala they are still in use today, even in printed form.) In the Classical era of the Maya, the days were identified as the number-name of the Tzolkin, followed by the number-name of the Haab. The two calendars of 260 days and 360 days would not repeat a combination of two names for 13 years.

The Haab Revised and the Long Count

After 747 BC the year changed to 365 and 1/4 days. The Olmec correction, like almost everywhere else in the world, was to add 5 unnamed days at the end of the year. For the Olmecs this was a 19th short "month" Uayeb of five days, called "the sleep of the year." Actually this would shift the year one day backwards in the solar year every 4 years, for it did not account for the quarter day left over. The revised calendar in Peru actually added a leap day every four years. Mesoamerica through Classical times did not, with the exception of the Zapotecs at Monte Alban (after about 400 or 200 BC).

In 747 BC the Olmec also started to count days, perhaps to recalculate the length of the year after the Earth shock of 747 BC. This is known as the "Long Count" which was carried into the future without interruption for the next 2700 years, but was mainly used by the Maya until about AD 900. The count started on February 28 of 747 BC (actually the Julian year of -748) with all measures set to zero -- zero days (Kins), zero months of 20 days (Uinals), zero "double-decades" of 20 Tun years (Katuns), and zero years of 360 days (Tuns). In our notation of these Katuns, Tuns, Uinals, and Kins, the Long Count is rendered as 0.0.0.0 February 28, -748.

This is also the date of the start of the Babylonian "Era of Nabonassar" (which starts at nightfall of February 27th), and the same calendar day after which the Romans restarted the year since the 8th century BC. [\[note 8\]](#)

A larger unit, called a "Baktun," consisting of 20 "Katuns," (400 Tun years of 360 days) was added at the same time or at a later date. A starting "Baktun" value of "6" was assigned to February 28 of 747 BC. The official Long Count date for February 28 -748 (using our dotted notation) thus reads "6.0.0.0.0 11-Ahau 8-Uo," where "11-Ahau" and "8-Uo" are the day names in the rotating Tzolkin and Haab calendars. (This is based on the August 11 correlation of Thompson.) The odd day-names, both located in the middle of the Tzolkin and Haab calendars, confirm that the Tzolkin and Haab were already rotating simultaneously before this time.

It might be possible to estimate from this when the Haab was first instituted, or what the general plan for the Haab was. Others have suggested that it is likely that the summer or winter solstice was used to celebrate the start of the year. But this notion reflects our contemporary reductionist calendar concepts. It also reflects our thinking that calendars should start at the first day of the first month. That is not at all certain.

Some people in Guatemala celebrate the New Year at the winter solstice, or at Christmas. This is when the Haab recycles for them. But it is the 9th month of the Haab. But it is also possible, as I pointed out above, that the Haab calendar and its later extra 5-day "month" were instituted without regard for an elegant design, and was arbitrarily added to the existing Tzolkin. [\[note 9\]](#)

What is of greater interest is to know how soon the Haab was corrected by adding 5 additional days. By the 18th month (of 20 days) after February 28, 747 BC, it would have been obvious that the year was now longer, and a 19th short month should be added. But since the Olmecs kept track of the setting position of the Sun by days of the Tzolkin and Haab, it is likely they had a much earlier indication of how many days the year had slipped behind.

The intercalated 5 days were added probably as soon as the first one of the longer years was about to pass. The traditional use of the Haab in the Classical era adds the extra five days after the 18th month, Cumku. In fact it was added at the end of the first new longer year, as can be confirmed from the current usage by the Chiapas (see below). Otherwise there would not have been the amazing simultaneous coincidence with the start of the Era of Nabonassar.

Verification that the 5 days were added after only one of the old years had lapsed, comes from the practices of contemporary upland Maya in Chiapas, Mexico, who retain a form of the Haab calendar today. The contemporary Haab calendar, in this instance, starts directly after Christmas, that is, a few days after the winter solstice. No accounting is made of the fact that the calendar will slip backwards against the Gregorian calendar. Somehow an extra day is added every four years.

The year starts with a Haab month which, from its name, is the equivalent to the ninth month of the older Haab of antiquity, and continues in sync with the Haab of antiquity. The second month of the contemporary calendar is the 10th month of the old Haab, etc. There is one exception. The intercalated 5 days are placed after the third month (of 20 days), not after the last month. The third month of 20 days ends on February 24. The intercalated days start on February 25 and conclude on the day after February 28. [\[note 10\]](#)

The use of the Long Count, and especially the starting value of 6 Baktuns, shows that an historical awareness had developed by 747 BC. Six Baktuns represent 2400 solar years stretching back in time to 3147 BC. The Olmecs figured the past on the basis of 360-day years, but the actual length of the year does not enter the basic calculation of when the current era started. A Tun was a solar year; the length did not matter.

The Long Count rotates through Tuns of 360 days (18 times 20), and all the future uses of the Long Count disregard the 365-day Tuns, and counted instead in 360-day Tuns. This is rather amazing, and probably confirms that the Long Count was started simply to measure the new number of days in the year.

Of course what we do is to use 365.24 days as the length of the year, and simply count backwards by days (called the Julian day count). Within a few hundred years after 747 BC, the Olmecs ended up doing the same thing, that is, using 365.24 days. The prior year length of 360 days used by the Long Count was ignored or forgotten.

That the Long Count was started in 747 BC is apparent also from the fact that 6.0.0.0.0 of the

Long Count falls on February 28, 747 BC, but also from the fact that this date completes a Katun 11. Katuns are named after the last Tzolkin day of a Katun; in this case the day 11-Ahau. This last is significant when we know from the 16th century AD Maya *Chilam Balam* that all of pre-history always was assigned to Katun 11-Ahau.

Some 1400 years later, in circa AD 700, the Maya at the site of Palenque retrocalculate dates 3000 years earlier, and list them according to the notion that the past -- all of the past -- consisted of 365 day Haab years, not 360 day Haab years. The Maya (or their Olmec predecessors) also retrocalculated back to the very beginning of the current era (the "second creation") to find that the initial Haab and Tzolkin days name and numbers were 8-Cumku and 4-Ahau. This works for both the "August 11" and the "August 13" concordance.

What does not work in this retrocalculation, is finding a Katun 11 ending for the previous era. The previous era ends in 4-Ahau, and thus the previous Katun is named Katun 4-Ahau. Despite this, when the *Chilam Balam* (in Book 10) recounts events from before the start of the current era (before 3147 BC, but thought to be 3114 BC), they are listed as happening in Katun 11. The notion obviously is from the time in 747 BC, when the Long Count was instituted as a Katun 11 had just ended. See the chapter "The Chilam Balam Books."

**A Person: 20 digits and toes (day names)
13 Day Numbers ($20 \times 13 = 260$ days)
18 months of 20 days ($18 \times 20 = 360$ days)
19th month of 5 empty days (= 365 days)
819 days rotated against four cardinal directions
9 Lords of the Night**

Of course the rotating calendars make no sense. Only the Long Count makes sense. One could tell how far in the past an event had happened, but only in terms of months (Uinals), which fell short of a cycle of the Moon, and years (Tuns) which fell 5 days short of the solar year. A relationship to the solar year could be kept by celebrating New Year at the summer (or winter) solstice, although solstice dates are not easy to determine. In fact, none of the people of the Central Valley of Mexico or the Maya of Mexico or the Guatemalan Peten celebrated or marked a solstice date, with the exception of the Chiapas mentioned above who remodeled their calendar to fit a Christian liturgical feast day near the winter solstice.

The actual day-name and day-number of a New Year day would change with each year. In the Yucatan the Maya of the Classical era celebrated the new year on July 26, when the Sun passed directly overhead at the site of Edzna, as did the people of Teotihuacan in Central Mexico (circa AD 200).

The simultaneous rotation through the 260-day cycle and the 365-day cycle would repeat every named day combination only once every 52 years (actually 52 "tun years"). That was of course significant in that it reflected the "traditional" possibility of reaching the end of creation (the so-called "52-year Venus cycle"), as was initially determined in the period

between 2349 BC and 2193 BC.

The 365-day year, without leap days added, also kept exact pace with the synodic period of Venus, which was probably much more important than any other considerations. As long as there was a strong interest in the movements of the planet Venus, it would make sense to not add the leap day, and retain the traditional calendars. The complex Tzolkin and Haab calendars spread everywhere in Mesoamerica, but the Long Count only saw wide use by the Maya.

The Katun Cycle

After circa AD 900 the Maya give up on the Long Count which had reached back 1500 years (4000 years if retrocalculated), and continue to use only a short cycle of Katuns -- 20 years of 360 days, about 19.7 solar years total for each Katun. Consecutive Katuns were collected in a repeating series of 13 Katuns (rather than the 20 Katuns constituting a Baktun), because the ending day-names of the Katuns repeat after 13 Katuns.

The cycle of 13 Katuns is approximately 256 solar years. This series is all the Maya retain of their calendar, 600 years after the collapse of their kingdoms -- plus, of course, the endlessly repeating assignment of days to the Tzolkin, the Haab, and the "Nine Lords of the Night."

Consecutive Katuns always are listed as starting with Katun 11, named after the last day, 11-Ahau, and are followed by Katun 9, etc., with the series of declining even numbered Katuns after the last of the odd-numbered Katuns, Katun 1. This is seen in use in the 16th century AD Maya *Book Of Chilam Balam*.

Others have suggested that this is because Katun 11-Ahau **begins** with 1-Imix, the first day of the Tzolkin. But in fact it is because a Katun 11-Ahau **ends** on February 28, 747 BC (-748), when the Long Count (6.0.0.0.0) was instituted (using the "August 11" correlation). Katuns are named after the name of the last day of the Katun period, not after the day with which they start (as we would do). It was always the completion of a time period, not the beginning, that mattered. For the Maya, unlike for us, a period of time did not **exist** until it was completed; it also did not exist yet while it was still ongoing.

The Four Ages

The concept of "suns" or "sun ages" was recognized throughout Mesoamerica by various peoples, as well as by people in many other parts of the world. (And has become a big deal among catastrophists.) These ages are meant to represent various creations of the world, or recreations after a catastrophic destruction. In Mesoamerica four ages were recognized by all except by the Toltecs and the Aztecs, who claimed that the world had been recreated five times. Both of these people held their own invasion of the Valley of Mexico as the last recreation of the world.

The creations and recreations can be pinpointed, but the series of dates runs into conflict with various concepts of what constitutes a new age.

The Olmec and Maya Long Count calendar starts the "current creation" in (the retrocalculated year of) 3114 BC. This date does not count the two destructions of the Earth since that time, but only recognizes that conditions on Earth and in the skies were completely different before and after. This was known as the "second creation," and from this two ages are recognized.

Book 10 of the Maya *Chilam Balam* books places creations or recreations after floods, and thus recognizes three eras, the periods before and after 3114 BC, and the period after 2349 BC, this last started with an event known as the "third reign" or what would be the "third creation." But the dark skies after 1492 or 1440 BC are also dealt with as the start of a new creation. It is not surprising that this confusion exists, since Book 10 of the *Chilam Balam* is obviously derived from diverse sources.

The concept of "four ages" is a satisfying shorthand if we associate a change of the length of the year with each of the ages, and especially if these events can be associated with some worldwide catastrophe. But it does not work out that way. What can be gathered from the most reliable source, the *Chilam Balam*, is the following:

- There was a very early age, suggested in the *Popol Vuh* and detailed in Book 11 of the *Chilam Balam* -- the long period before the darkness of the Younger Dryas. And then followed the lighting up of the southern ball plasmoids in 10,900 BC. That was the start of the "first creation." This ended in 8347 BC, and marks the ending of the "first creation." This particular time period is generally not recognized at all by most catastrophists.
- The "second creation" ends in 3147 BC. References to it are only implied in the text of the *Chilam Balam* from the fact that the "third creation" ends later, in 2349 BC. The second age is thus the era between 8347 BC and 3147 BC, and includes (as the last thousand years) the "Era of the Gods."
- The end of the "third creation" is the event we know as the "flood of Noah." Book 10 of the *Chilam Balam*, however, places the "third creation" (incorrectly) in Katun 9-Ahau ending in 2266 BC. It should properly be placed in Katun 4-Ahau ending in 2345 BC.

The fall of the Absu, the end of the "third creation," is noted as "the second baptism" with the implication that the first is the flood of 3147 BC (which is also mentioned). The *Chilam Balam* also implies the start of a new calendar. In this it parallels the Chinese *Annals of Shu*, as well as the Babylonian *Enuma Elish*.

- Despite the fact that Jupiter had burst into flames and lost its coma, disappearing from the skies in about 2150 BC, Jupiter remained the ruling God. Likewise the change in the Earth's orbit in 2193 BC was not an event which defined a new era. The era of the "third creation" continued.

- The electric contact by Venus in 1492 BC starts yet another age, the fourth. In fact the *Chilam Balam* notes that Venus "rubbed the Earth" in Katun 9-Ahau ending in 1486.2 BC (corrected), although this was likely the view of the Van Allen belts in glow mode. A new creation is also to be inferred from the mention of the establishment of the trees of the four cardinal directions. This is the third reference in the document to these trees, noted previously after 3147 BC and 2349 BC.

There is also a reference to "walking in darkness," which can be identified as the 40 years or so after the contact by Venus in 1492 BC. The Israelites also "walked in darkness."

"Then they perceived that the world was being created. Then creation dawned upon the world."

The reference to creation is suggested for 1492 BC by its placement in the texts, but could also refer to the 200-year climatic downturn experienced worldwide after 2193 BC.

- There are no further ages referenced. The year 747 BC, which occluded the Sun for two days and changed the orbit of the Earth, had no bearing on the list of ages. The Earth shock of 686 BC could have represented the start of yet another age, but the *Chilam Balam* specifically states that this was not to happen (a retrospective comment). Similarly, the nova event of 685 BC is mentioned but not counted as a new era. In actuality, the understanding was that the world was rescued from Mars by Jupiter.

I suspect that the *Chilam Balam* was transcribed from books indigenous to the Peten and Yucatan Maya. The story of these books may have differed from the records kept among the Olmecs of Veracruz and in the Valley of Mexico, which have not survived.

But we can count four ages from Olmec sources under a completely different paradigm: the site alignments used in the Olmec coastal area since 1440 BC, and in the Valley of Mexico since about 600 BC.

These horizon alignments for sunrise or sunset reference four dates. First, starting at San Lorenzo and followed by almost every later site, the date of April 19, 1492 BC is recalled in the alignment of the setting Sun to some mountain or volcano. Apparently when San Lorenzo was established, the horizon location of the setting Sun for that date was known.

Similarly, at La Venta the alignment for February 28, 747 BC was also known, since it was experienced. After 747 BC the date of August 12, 3114 BC, was calculated with the aid of the newly developed Long Count. Various dates centering on July 685 BC, were also experienced and incorporated into the alignments of sites after 685 BC.

Last, in about AD 200, and at some locations, both since before and directly after 685 BC, the setting of the culmination of the Pleiades is used to signal the event of 2349 BC. These alignments show up at all later sites. The alignments are discussed in the chapter "Olmec Site

Endnotes

Note 1 --

The dotted notation, used by archaeologists as a shorthand to identify the Long Count, consists from left to right of measures known as Baktuns, Katuns, Tuns, Uinals, and Kins.

These are thus written in modern form as as Baktun (dot) Katun (dot) Tun (dot) Uinal (dot) Kin. A dotted notation is always followed by the Tzolkin day number and day name combination plus the Haab day number and month name combination.

- Baktuns are sets of 20 Katuns, or 400 Tun years, representing 400 years of 360 days (surprisingly, not 365 days). A Baktun represents about 256 years of our calendar. The word "Baktun" is an invention of archaeologists. The Maya simply called it "400" in representing 20 times 20. The count goes from 1 to 13.
- Katuns are double decades, representing 20 of the 360-day Tun years. The count goes from 0 to 19. This is about 19 years of our calendar.
- Tuns are "years" of 360 days. The count ranges from 0 to 19.
- Uinals are "months," where each count represents 20 of the day counts. Uinals range from 0 to 17. On reaching 18, the next higher number (the Tun) of the dotted notation is advanced one. 18 Uinals thus represent a Tun year of 360 days.
- Kins are days and count from 0 to 19. On the 20th count, the next higher number (the Uinals) of the dotted notation advances one. Kins (days) thus count up to one Uinal "month" before advancing the next higher count.

Note 2 --

For Long Count dates which were retrocalculated by the Maya in circa AD 700 at Palenque, as well as the correction of the Katuns (where I have supplied the Baktun) of Book 10 of the *Chilam Balam*, a correction should be used. This will be based on the suspicion that there did not exist a record in actual Long Count days for events before 747 BC, but only a listing by Katuns and Baktuns. This correction is easy to do: Since 6 Baktuns were added to the dotted date of 0.0.0.0, the starting date of the current era would have been 2400 years earlier (6 times 400), and thus 747 BC less 2400 years: 3147 BC.

The start of the yet earlier era would be 3147 BC less 13 times 400 years: 8347 BC.

For the inscriptions at Palenque the correction should be based on the fact that the Olmecs knew that the era prior to 747 BC represented years of 360 days, not 365.24 days. But this

was long forgotten 1400 years later when the Maya of Palenque start carving monumental inscriptions. Our calculations and those of the Maya of Palenque are based on a 365.24-day year, and would be off by 5.24 days per year before 747 BC, that is, the dates we use are placed too far into the past. The correction is $(3114-747) * 5.24 / 365.24 = 34$ years.

So, for example, when in AD 700 the Maya at Palenque retrocalculated a date of 2360 BC for some event listed among the inscriptions, it was based, like our calculations, on a 365.24 day year, and would be too far into the past by $(2360-747) * 5.24 / 365.24 = 24$ years. The date should be 2336 BC.

The Maya were perfectly capable of calculating backwards, and making allowances for the extra 0.24 day of the year. Anthony Aveni, in *Skywatchers of Ancient Mexico* (1980), notes a number of instances among Maya inscriptions (at Copan) where successful attempts were made to indicate the length of the tropical year. The Maya ended up with a year of 365.2420 days, only 0.0002 days different from the current value of 365.2422 days.

[\[return to text\]](#)

Note 3 --

See the chapter "The Chilam Balam Books" for a retelling of the creation of the world which dates back to thousands of years before 3114 BC and was apparently transcribed from Maya tree-bark codexes. Other pages of the *Chilam Balam* describe the darkness of the Younger Dryas (10,900 to 9,000 BC), and hint at yet earlier ages dating to the equivalent of the European Magdalenian period (17,000 to 14,000 years ago) or earlier (I suspect to 41,000 years ago).

[\[return to text\]](#)

Note 4 --

The Maya (and Olmecs) used a base-20 in their commerce, but it is difficult to maintain that they also did so with their calendar, as is often maintained. The "units" of the Long Count do not all advance as powers of 20, since the Uinals advance when reaching 18, not 20. Baktuns cycle at the number 13. The number 20 just happens to be a larger unit to count in, like our dozen or hundred. The glyphic representation is certainly in base-5.

[\[return to text\]](#)

Note 5 --

Although some of what I have suggested is conjecture, I should note a remarkable similarity of the Mesoamerican 20 day names and 12 day numbers to the calendar of the Chinese Shang dynasty, after about 1400 BC, which rotated 10 "celestial day names" (instead of 20) against 12 "earthly day names" to produce a similar calendar (of 60-day periods), elements of which lasted well into the current era. The Chou dynasty extended the rotation of 60 day names to the names of years. This last persists today.

Although the Shang dynasty is much later than the period under discussion here (before 2349 BC), it would not be at all surprising if the Shang calendar represented a holdover from an earlier period, when the 240-day year was divided into four seasons of 60 days each, thus a total of 240 days. China experiences four distinct seasons; Mesoamerica experiences a completely different cycle of seasons. The Shang, at any rate, added the lunar month days to the 60-day periods to furnish nearly accurate calendar dates during the year.

[\[return to text\]](#)

Note 6 --

I suggest a year of 273 days, based on conjectures developed later in this text. Since 273 is 13 days more than 260 days, the Tzolkin could have been expanded by adding one round of 13 numbers, or the calendar could have been left to slip backwards 13 days per year. The reason for selecting the second might have depended on an initial attempt to keep the calendar in line with the half-moon periods of the previous era. This did not work out, for the Moon changed to a period of 27 or 28 days after 2193 BC, which we know from (later) Shang oracle records.

[\[return to text\]](#)

Note 7 --

It is possible that the Haab was devised separately by a people different from those who devised the Tzolkin, and the two calendars were kept after a cultural merger after 1500 BC.

[\[return to text\]](#)

Note 8 --

According to Ussher, the era of Nabonassar starts at noon of February 26th, thus actually on the 27th. Ussher writes:

"From twelve o'clock, on the first day of the Egyptian month Thoth, from Wednesday, February 26th, in the evening, in the year 747 BC, all astronomers unanimously start the calendar of Nabonassar."

-- James Bishop Ussher, *Annals of the World* (AD 1650)

Additionally, because of the Mesoamerican concepts that a day does not exist until it is completed, the Long Count use of "day zero" actually signifies the first day of the new era, so that the actual era-ending date is February 27th.

[\[return to text\]](#)

Note 9 --

The short five-day month can be neglected in any retrocalculation here, because it was

instituted in 747 BC. If we take a hint from how the Olmecs dealt with other calendar adjustments, it would suggest that the Haab was instituted the day after the completion of the cataclysm of 1492 BC. From an earlier chapter we know that this happened on a Gregorian equivalent calendar date of April 19. (Bible tradition, for the start, is April 17th.)

On February 28, 747 BC, the Haab day fell on 8-Uo. This is the 29th day of the Haab. Thus, in 747 BC, the annual secular calendar, which starts with 0-Pop, had started 29 days earlier in that year, equivalent to January 30 on an equivalent Gregorian calendar. Thus, between April 19, 1492 BC and February 28, 747 BC the Haab had slipped 80 days backward, which is four 20-day Uinal months. This number is not in any sense meaningful.

Alternately, taking into account the fact that before 685 BC the winter solstice fell some 15 days earlier, on December 8, the Haab would have restarted 53 days after the winter solstice. Except for the fact that 53 days represents a 52-day interval, this also is such an arbitrary figure, that it can only be suggested that there was no relationship between the Haab and either the winter or summer solstice.

Vincent H. Malmstrom, in *Cycles of the Sun, Mysteries of the Moon* (1997), dates the first use of the Haab to 1324 or 1321 BC, based on placing the day 0-Pop (the first day of the Haab) at the summer solstice. The calculation would only be in error by 8 years, since the extra five days have to be subtracted from the Haab for the period before 747 BC. But also it is absurd to think that a beginning date (0-Pop) would be at all meaningful in Mesoamerican chronology.

The usage of the Chiapas (see other endnote below) might bear out Malmstrom's conjecture that the New Year (the start of the Haab) was celebrated at the summer solstice, even though the Chiapas today start the year with the winter solstice (actually at Christmas), for they start with the ninth month (Uinal) of the traditional Haab calendar. The name of the month which starts the Haab is clear from the fact that the names of the first few months of the Haab translate to "first," "second," "third," etc. That would place the beginning of the Haab 160 days before Christmas (8 completed months). This is not at the summer solstice, but 24 days later, on July 18.

When New Year is celebrated is a local option. The Maya, as with Teotihuacan, used July 26. In colonial times the Aztecs celebrated the start of the new year on February 26. (There are some discrepancies with respect to this particular date, however. See the endnotes to Appendix B, "Celestial Mechanics.")

[\[return to text\]](#)

Note 10 --

See Gary H Gossen, "A Chamula solar calendar board from Chiapas, Mexico," in, Norman Hammond, editor, *Mesoamerican Archaeology* (1974). Although the Tzolkin was held as sacred, the Haab was apparently adjusted to start as convenient by various tribes.

Introduction

The *Chilam Balam* books are a collection of post-colonial (16th century AD) native manuscripts in the Mayan languages, using the Latin script, which recorded histories and prophecies, many dating back with certainty for hundreds of years, while Books 10 and 11 plus some single pages recollect events dating back thousands of years. All of it is presented in terse and obscure language.

I am tempted to repeat the statement by Hertha von Dechend about "the annihilating recognition of our complete ignorance" for I was struck with the same feeling on first reading the *Chilam Balam* -- I could make absolutely no sense of any of it. It took me six months of daily application to digest Book 10, and much longer to unravel Book 11.

Book 11 recalls events leading to the creation in 10,900 BC of the ball plasmoids of the south. This is the "first creation." Book 11 may include events dating back to circa 30,000 or 40,000 BC. A separate single page of the *Chilam Balam* specifically recalls the "survey of the world" in the period after 10,900 BC, while yet another single page recalls the fall of the Absu in 2349 BC. These additional texts from the *Chilam Balam* will be presented in the chapter "The Olmec Record."

What follows below is an attempt to "read" Book 10 in terms of the chronology of celestial events which I had already established on the basis of information from the Eastern Mediterranean region, India, and China. Book 10 deals with the "second creation" and subsequent events, including the "third creation."

The Book Of Chilam Balam Of Chumayel was translated into English by Ralph L Roys in 1933, based on original sources, and compared to other extant documents and other copies of the *Chilam Balam*. It is not easy to read, even though the text is supplemented with extensive footnotes and added commentary. One of the stumbling blocks is the mention of many Maya Gods which are still obscure and difficult to identify today. A copy of *The Book Of Chilam Balam Of Chumayel* is on line at [\[www.sacred-texts.com/nam/maya/cbc\]](http://www.sacred-texts.com/nam/maya/cbc).

I first looked at the *Chilam Balam* after I had written most of the text of these pages. In Book 10 of the *Chilam Balam*, in a section labeled (by Roys) "The Creation of the World," I ran into a phrase which caught my attention:

"Then there came great misery, when it came about that the sun in Katun 3-Ahau was moved from its place for three months."

If there is one thing for certain, it is that since the Sun first appeared, it has never moved, acted up, or changed its look in human memory -- except, of course, in 685 BC, as I had already established. Could this be a record of the nova event of the Sun and the blazing of Venus and Mercury of 685 BC (680 BC in Eastern Mediterranean chronology), when the polar axis relocated, the dome of the sky twisted, and the vernal equinox moved suddenly to another zodiac sign?

A calculation showed that the first 20-year Katun 3-Ahau period after 747 BC started in 687 BC (6.3.0.0.0), two years before my estimate for the nova event of 685 BC, and ended about 20 years later. A closer reading of the remaining text soon convinced me that this Book retold other events dating back to before 3100 BC. And ends, as does everyone else's record of the catastrophic past, in 685 BC.

The clearest indication of these events were descriptions of interactions between Jupiter and Saturn (and their satellites) which can be placed for certain in 3147 BC. It is described with uncanny accuracy -- if we are allowed to transfer the names of two sets of obscure Gods, "The Thirteen" and "The Nine," to Saturn and Jupiter. The remainder of the text of this chapter provides the details. This portion (called a Book) of the *Chilam Balam* recounts what is known among the people of Mesoamerica as the "second creation" and subsequent events of the "third creation" and a possible "fourth creation" through 685 BC.

The Katun Cycle

First a word should be said about the cycle of 13 Katuns in use by the Maya at the time of the Spanish invasion. After Classical times (circa AD 900), the Maya dropped their "Long Count" dating and reduced their calendar to a repeating cycle of 13 Katuns (which was in use already long before AD 900). Each Katun consists of twenty Tuns, that is, twenty 360-day years (not the 365-day Haab years) and thus 19.71 of our Gregorian years, each named after the last day of the period in the Tzolkin day nomenclature. This, as it turns out, is always one

of the day-numbers 1 through 13, followed by the day-name Ahau. The Katuns are named, in order, 11-Ahau, 9-Ahau, 7-Ahau, etc., skipping a day-number for each consecutive Katun. The complete cycle of 13 Katuns is approximately 256.26 actual current years.

Because of the Maya philosophy of cyclic time, only this single cycle of 13 Katuns was recognized, and all events were placed within a listing of this cycle, although at times other Books of the *Chilam Balam* texts will list Katuns as a series extending over many cycles. But often events separated by 256, 512, or 1024 years are all listed for the same Katun. Thus when an event is said to occur in Katun 4-Ahau, it could have happened in any 256-year interval of the past, or even be a prediction for the future. It is, in fact, the predictive value of this calendar that forced the Maya to consider that all events of the past had been accomplished in a single repeating cycle, and would happen again. [\[note 1\]](#)

In the text below, I have added corrections to the (retrocalculated) Gregorian years to show solar years, based on the indication that the Long Count was started in 747 BC, on a day matching similar efforts at calendar reform in the Eastern Mediterranean. The Olmecs added 6 Baktuns to a count set at 0.0.0.0 on February 28, 747 BC (the completion of the disturbance). Thus to correct for our insistence in calculating backward in time under the assumption that the year was always 365.24 days (as the Classical Era Maya also did), we can place the Long Count date of 0.0.0.0.0 at 6 Baktuns before 747 BC, at 3147 BC.

The corrections are then made by counting forward in time with **3147 - 400 * Baktuns - 20 * Katuns** up to 747 BC (even though the year 747 BC on which this is based is actually -747).

Retrocalculation for dates from the sculptures at Palenque (circa AD 700) require a different method. This has been covered in chapter 20, and takes into account the difference between 360 and 365.24 days in the year. The recalculated dates in this chapter match the corrected Eastern Mediterranean chronology, with some exceptions, which can be attributed to the attitudes of the Maya to the very concepts about time, and which will be explained below.

Katun 11-Ahau: History Starts

Bishop Diego Landa destroyed hundreds of Maya glyphic manuscripts in the 16th century AD, but it is likely that many remained, for even 100 years later missionaries were reading prophecies from original bark books (as, for example, the Spanish missionary Avendaño, in AD 1696).

The *Chilam Balam* books had a different status than the original bark books. Written by the Maya in European notebooks, in the European script, but in the Mayan language, these formed a greatly condensed record of the histories, rituals, and prophecies from the time before the invasion of the Spanish in AD 1517. It was an efficient method of keeping in touch with the past. The books were kept from the Spanish priests, recited at village meetings, and copied and recopied for 300 years. The readers knew the context of the

information of these notebooks, although likely this was slowly lost over the next few hundred years. [\[note 2\]](#)

The *Chilam Balam* books all insist that the cycle of history starts with Katun 11-Ahau. Although Maya history recorded on monuments does not reach back before AD 300 or 400, their calendar was in universal use throughout Mesoamerica probably since 600 BC or earlier, and the predecessors to the Maya, the Olmecs, were probably responsible for the concept that history started with Katun 11-Ahau. Roys claims that this is so because the first day of Katun 11-Ahau starts with the day 1-Imix which is the first day of the 260-day Tzolkin cycle of naming days. But in the grammatical construction of Indian languages, a date (or Katun) does not exist until it is completed, which is why Katuns are named after their last day, not the first. [\[note 3\]](#)

My thinking initially was that the reason for starting history with Katun 11-Ahau is that the ending of a Katun 11-Ahau might have coincided with the calendar change in 747 BC, when calendars were changed worldwide, and in many cases initiated. It turned out that this guess was correct, a Katun 11-Ahau **ended** in 747 BC, in fact, on February 28th. This is the ending date also for the Roman annual calendar. And also the day before the start of the "Era of Nabonassar" used in the Babylonian Chronicles, and presented by Ptolemy in about AD 150 for his list of Kings of Babylon and his list of eclipses. This is the date that the year changed from 360 days to 365.25 days. The Babylonian day started at nightfall, so that the era actually started on February 27th.

All of this is not just a coincidence. The odds of a single 20-year Katun, out of a cycle of 13 Katuns, ending in the year 747 BC, is small. That it should fall exactly on the date before the start of the "Era of Nabonassar" is astounding. That this date would be represented by the Long Count of 6.0.0.0.0 is beyond belief.

Considering that the nova event of Venus in 685 BC also coincides with a Katun period of the correct name, I thought that perhaps some faith could be placed in these Katun dates, although I expected much of the information to be out of place. In fact, as I read through the text, I realized that most of the very old events were arbitrarily assigned to Katun 11-Ahau. I did not initially expect any of the other celestial events to be placed in Katuns which corresponded with known dates from the Middle East. But at the conclusion of investigating this text, it looked like all except two of the events were correctly placed. One was, I suspect, a transcription error, and the second was a deliberate change made during classical times (or earlier) to make the date of an important event coincide with a certain day-name of the Tzolkin (July 25th).

Many of the events recorded in Book 10 of the *Chilam Balam*, however, seem to be in the wrong order in going from one event to the next. It is as if some canonical source was misread, perhaps reading the left page before the right page from a book meant to be read from right to left (which, in fact, was the case for the Maya codexes). It would seem that in some cases only the information of single sentences occupied a full page of the original. That

suggests an illustrated codex with an appended text in glyphs.

Additionally, it looks as if the author had accessed three or four separate original sources, which do not match in format, although none of the events are repeated. I will indicate the suspected shifts from one source to another where I have become aware of them. [\[note 4\]](#)

As you can imagine, the *Chilam Balam* represents a giant sequencing puzzle, both because of the obscure sequencing of history and because of a few errors which were incorporated by the original copyist. It took me six months to get through the text initially, and I had to make a number of changes afterwards. Often a resolution of textual elements involved attempting to place myself in the position of a copyist who is earnestly trying to make sense of a document which related events from thousands of years ago.

But thanks to a cultural continuity, we can identify elements which were actual and which (from our point of view) had shifted to become metaphors. The greatest help in this was reading Linda Schele and David Freidel's book *Maya Cosmos* (1993) prior to tackling the *Chilam Balam*, for the authors identify many elements from the Classical Maya era, 1500 years ago, which still appear among the contemporary practices of Maya shamans. (I also was involved as equipment consultant for Peter Thompson's film *The Shaman of Oxkintok* about Don Chabo, a Maya shaman, in 1992 -- 1993, but known as *El Movimiento* when completed in 2001.)

In *Maya Cosmos* Schele and Freidel were eventually forced to consider the stars as a major element in Maya cosmology and show that this is part of religious practices of the Classical era and is still in current use. Thus when I ran into the "timbers at the crossroads" and the "precious objects," the equivalent in our terminology instantly jumped to mind, and without question. It has likewise been shown by Schele and Freidel that many concepts and ideas, it would be more proper to say "images," of the 16th century AD Guatemalan *Popol Vuh* were already being depicted in Classical times.

In the following I have kept the *Chilam Balam* text in the same order as it exists, with a few alternate readings by Bolio (see below), and some footnotes by Roys, added. That makes for a thoroughly confusing sequence, but I thought it more important to follow the original order of the text, rather than to make repairs which would only add to the confusion. As a reader you will thus be treated to constant interruptions, where events are taken up, interrupted by other unrelated events, and continued a paragraph or two later. Overall, however, the *Chilam Balam* sticks to a consecutive narrative. That will help.

The specificity of Roys's translation can be compared with a more recent translation by Suzanne D. Fisher, made from an earlier translation into Spanish made in 1930 by Antonio Mediz Bolio. Bolio has the distinction of speaking one of the Mayan languages, but this earlier Spanish translation by Bolio seems to be a composition based on the assumption that the original was written in similes and metaphors.

In a preface to a translation of Bolio's text into French, J. M. Le Clézio wrote, *"At times ... he seems to prefer the beauty of the expression to the literal meaning, which results in a profoundly emotional and poetical version."*

At times the Fisher translation after Bolio parallels the translation by Roys and is much more readable, but often it is altogether different. Thus the sentence I quoted above, about the Sun:

"Then there came great misery, when it came about that the sun in Katun 3-Ahau was moved from its place for three months. After three years it will come back into place in Katun 3-Ahau."

This is rendered by Bolio as:

"That is what is coming, when three moons have fallen in the time of the 3-Ahau Katun, and after three portions of years, trapped within the 3-Ahau Katun; ..."

Bolio, in the text shown directly above, assumes that the original is a comment on the sense of a previous sentence, which speaks to the coming of an "unending bitterness." Roys assumes the sentence starts with the mention of the "great misery" and places the agent in this phrase. Both the sense and the punctuation have been rendered completely differently.

At cause is the original text, where there is no indication of the starting and ending of sentences or paragraphs. Both Roys and Bolio had to guess at the implied punctuation. Bolio has the advantage of speaking Mayan, and often he has polished the text, but I too feel he has frequently lost the specific details. In Roys's translation, on the other hand, the tense and number of the verbs and nouns often bounce back and forth unpredictably. I will use Roys's text and augment it with the Bolio text as needed.

A copy of Book 10 is available locally at [\[saturniancosmology.org/book10.htm\]](http://saturniancosmology.org/book10.htm) which collates the text by Roys with some rephrasings by Bolio, some of the material from Roys's footnotes, and a few additional insertions, but without my extensive comments. I have added the numbered Katuns. The 16th-century scribe started in Katun 11-Ahau and continued in order through Katuns 11, 9, 7, 5, [8, 2], 3, 1). After Katun 5-Ahau, two even-numbered Katuns are inserted, Katun 8-Ahau and 2-Ahau. The sequence of even-numbered Katuns is skipped, but the text ends in repeating Katuns 13-Ahau, 11-Ahau, and 9-Ahau.

The Author's Introduction

Book 10 of the *Chilam Balam* is the history of the "second creation" of the world, and the appearances of the planetary Gods. With some exceptions, the information never deviates from the purpose of this presentation. The text is introduced by the original copyist with a note of urgency. The information is presented in the context of the new Christian God:

"It is most necessary to believe this. These are the precious stones which our Lord, the

Father, has abandoned. This was his first repast, this wine, with which we, the ruling men, revere him here."

"Very rightly they worshipped as true gods these precious stones, when the true God was established, our Lord God, the Lord of heaven and earth, the true God."

This section of the *Chilam Balam* is distinct from all other texts of the books in offering an introduction. The comment about the "precious stones" suggests that stones were used to represent events and represent the gods. The first Christian missionaries also told that the Maya "worshipped stones." The author here turns the "stone worship" of the Maya into a misdirected earlier effort. It might also be suggested that the Maya knew very well that the planetary Gods which were worshipped were indeed nothing more than large rocks. The close passages of Mars would have demonstrated that. In Book 11, "The Ritual of the Angels," a Maya author has the Christian "God the Father" emerge from one of the "holy stones" seen in the sky. Bolio in that case interprets "tun" as a "holy stone." It might serve the reader to think of "tun" or "stone" not as material ("made of stone") but as a shape, form, or container. [\[note 5\]](#)

The author continues with the introduction: (I have broken up Roys's long paragraphs throughout.)

"Nevertheless, the first gods were perishable gods. Their worship came to its inevitable end. They lost their efficacy by the benediction of the Lord of Heaven, after the redemption of the world was accomplished, after the resurrection of the true God, the true Dios, when he blessed heaven and earth. Then was your worship abolished, Maya men. Turn away your hearts from your (old) religion."

"(This is) the history of the world in those times, because it has been written down, because the time has not yet ended for making these books, these many explanations, so that Maya men may be asked if they know how they were born here in this country, when the land was founded."

NOTES:

- () insertions by Roys in the translated text,
- [] insertions are by me from footnotes or from Bolio.

The writer acknowledges that his sources are other books. He then proceeds to list events, starting, naturally, with Katun 11-Ahau, where the cycle of all history is understood to start. The first few lines relate events which happened before 4077 BC and in 3147 BC. He then progresses through additional Katuns in turn, but only up to Katun 3-Ahau, which Roys thinks is an interpolation (in this particular version of the *Chilam Balam*). He then very briefly speaks of the miseries of Katun 13-Ahau and touches again on Katun 11-Ahau and Katun 9-Ahau as a recitation of more recent history. This is followed by portraits of Saturn and Jupiter as the two ruling Gods. Here is a list of topics, in brief outline:

- Katun 11-Ahau - The Bee Gods and The Thirteen; the fire, the rope; the capture of The Thirteen by The Nine; Nine-Lives escapes; flood and fallen sky; four trees (the period of 4077 BC to 3147 BC).
- Katun 9-Ahau - Ten-Sky appears (3067 BC to circa 2700 BC);
- Katun 7-Ahau - Uuc Chek-nal comes; Earth and Heaven touch (1492 BC).
- Katun 7-Ahau - A new world created (after 1442 BC).
- The "third creation," the Moon rules all of Earth (wrong Katun?).
- Katun 2-Ahau: Jupiter seated, gravediggers, crossroads revealed (2349 BC).
- Katun 8-Ahau: fire on high (2150 BC).
- Katun 3-Ahau - The Sun leaves its path (685 BC).
- Katun 13-Ahau - Misery, foreigners.
- Katun 11-Ahau - Nine-Lives shows (776 - 747 BC).
- Katun 9-Ahau - Nine-Lives descends, flowers (747 - 727 BC).
- Fall of the Absu (placed in 2250 BC, wrong date).
- The rulership of the Thirteen.
- The rulership of the Nine.
- The return of Kukulcan.

At first I was not always certain of how some of the descriptions translated to the chronology I had set out earlier in these pages. But allowing for the author's error in reading the order of the original texts, the insistence of sorting events by Katuns, and the additional quirk of failing to note repeating events, all of it eventually fell into place. What I am certain of is that very little is metaphorical. Much of it is simply descriptive, even though the language is one of the Maya's environment of stones, trees, flowers, and plants.

The distinct advantage to us of the *Chilam Balam* as a source for a history of the "Era of the Gods" and the period following, is its insistence, based in the original Mayan language, of describing actions rather than static states. In contrast, Egyptian or Mesopotamian sources deal almost entirely with static states.

The Thirteen: Saturn

The following are the first lines. The author starts at the very beginning, the first clear sight of Saturn in 4077 BC. I am translating "Oxlahun-ti-ku" as "The Thirteen" on the basis of Roys's footnotes. From the remaining context it is obvious that "The Thirteen" is Saturn, just as "The Nine" will turn out to be Jupiter. Together with the next few lines, we have here a condensation of the 3000 years of history of the Saturnian apparition to a few lines:

"It was (Katun) 11-Ahau when the Ah-Mucenca [the bees] came forth to blindfold the faces of the Oxlahun-ti-ku [The Thirteen]; but they did not know his name, except for his older sister [Uranus?] and his sons [the other planets?]. They said his face had not yet been shown to them also."

Only after reading ahead did I realize what was happening here. First, about the bees. "Ah-Mucenca," Roys relates in a footnote, are supernatural bees or bee-Gods. In conjunction with the following lines, these are likely to be satellites of Saturn, buzzing around the hive like bees. (These bees, and the hive, occur elsewhere in the *Chilam Balam* when much earlier history is being discussed.) [\[note 6\]](#)

"Oxlahun-ti-ku," Roys notes, "*literally the Thirteen Gods, are probably the gods of the thirteen heavens of the Maya cosmos, but they are usually treated as a single god.*"

I would suggest that "The Thirteen" is Saturn, represented by the seven most prominent satellites which could be visually distinguished because of the proximity to Earth, plus the count of Uranus, Neptune, Saturn itself, Venus, Mercury, and Mars (a count of six). All of these planets are recognized on other pages of the *Chilam Balam* as part of the stack of planets seen since long before 10,900 BC, and noted also in the *Popol Vuh*. If Uranus is his sister, then perhaps the other planets above and below Saturn would be his sons. [\[note 7\]](#)

"The Thirteen" may also represent (as Roys notes) the thirteen levels of heaven imagined to be located physically above the Earth in the Maya cosmology, although I think this is likely a more recent addition to the theology. That the upper reaches of the sky are assigned to Saturn would follow from the fact that Saturn had stood above the Earth for six thousand years. On the other hand, Jupiter (known as "The Nine") is assigned to the nine levels of the Underworld, for he was only seen on the ecliptic, and thus dipped below the Earth each night.

The arcane text about "not knowing his name" may relate to the fact that a theology of these Gods was never adopted by the Maya. It has been noted (Schele and Freidel) that the earliest archaeology of the Pre-Classical Maya shows no signs of the Gods of the (later) Classical era, but I am not so sure what that means. It is clear (at least to me) that by classical times the Saturnian planets were incorporated in the theology. A look at the "altars of the cross" at Palenque, erected in circa AD 690, show that the concern was entirely with the most recently active planets: Jupiter, Venus, and Mars. At this time Saturn had been reduced to an old man. [\[note 8\]](#)

Similarly the concern with directional trees (see the text further below) has been found as four trees set in sockets at the top platforms of the earliest temple platforms of the Maya dating back to 200 and 100 BC. The iconography of the four trees first shows at Olmec La Venta, circa 650 BC, carved as four small sprouts surrounding a central figure, although archaeologists tend to identify the four sprouts as corn seedlings. In terms of the *Chilam Balam*, this would signify a continuation of Gods, for the directional trees are part of a mythology or history stretching back to 3100 BC -- some 1500 years before the Yucatan was first populated.

It should be recognized that the Maya, like the surrounding peoples of Mesoamerica, were "converted" at some point after 600 BC to the philosophy (and history) expounded by a set of

graphical books which were obtained from centers in the Valley of Mexico, Veracruz, or Oaxaca. This was absolutely convincing, since the books so obtained matched their own recollections and records. I'll expand on this in following chapters.

Back to the bees: I assume here that "they" means the sons and sister, not the bees. This is consistent with the information of the *Popol Vuh*, except that Saturn itself is counted.

Bolio assumes that The Thirteen did not know the name of the Bee God (which he has as singular). The "older sister" is likely to be the much larger Uranus, which was involved with this configuration from the very start, and would look to have long hair because of the outpouring of plasma from its horizontally located south magnetic pole, where the other pole only showed a beak-like plasma in glow mode.

The north magnetic pole plasma outpouring was not identified as a bird beak, as in European Upper Paleolithic and early Neolithic iconography. It may have been identified as a nose of the figure. It may account for the facial disfigurement practiced by the Maya.

The "sons" would be the other planets which traveled with Saturn. If these, together with Saturn, add up to six, then Venus would be included among them. Thus we can date this description to after 4077 BC, since Venus would not show up until after 4077 BC, although the wording here seems to be speaking of an earlier time.

That the Ah-Mucenca bees blindfolded Oxlahun-ti-ku, Saturn, is not as curious as it might seem at first. The writers of the *Chilam Balam* had determined this from an inspection of a book of ancient history, composed entirely of graphical images. It suggests a coma occluding Saturn, and perhaps the other planets, which, by the way, other peoples have noted also.

The text continues with the obvious, declaring that this time is already after the creation of Earth, that is, the world. I should point out that the Olmecs were certain also of an earlier creation, a "first creation," which is detailed in Book 11. The purpose of the book considered here (Book 10), obviously is to provide the history of the Gods which were honored in Classical times, and thus will describe the "second creation" (ending in 3147 BC) and the "third creation" (ending in 2349 BC). Other pages or books of the *Chilam Balam* will also separately describe the "first creation" and again the "third creation."

"This was after the creation of the world had been completed, but they did not know it was about to occur."

Strange as the tense of this sentence is, it seems to say that something "unknown" preceded the existence of Oxlahun-ti-ku, Saturn. This is not unlike the myths of other people where we see "creation" proceeding from a misty chaos in the sky. The *Popol Vuh*, the story of the ball-playing twins, written in Guatemala at about the same time as the composition of the *Chilam Balam* books, describes the second creation as the undifferentiated mass of water or mist of the "chaos" found in other creation myths elsewhere in the world.

The blindfold stretched across the face of Oxlahun-ti-ku, Saturn, is possibly the creation of the rings in 4077 BC. At that time the satellites (the Bee Gods) would be clearly seen only if Earth were mostly below Saturn at that time. The problem with these texts is that we have no idea of what times in the past these snapshot images refer to.

However, to see the rings as a blindfold would place Earth mostly laterally with respect to Saturn. That also allows all the associated planets to be seen.

If this description were presented from sources in Mesopotamia or Egypt, I would immediately suggest that the "creation of the world" as mentioned above would be in reference to the "land" of Saturn -- Upper Earth. But I never get a sense of the stupendous object in the north skies being equated to anything other than a god-person -- with the exception of an equation of directional bees and a bee hive or pot of honey at the island of Cozumel in Book 11 of the *Chilam Balam*).

As I mentioned earlier, it is possible that the scribe here is relating the coma which was seen after the 2500 years of shadow of the Younger Dryas had lifted. This would suggest that the bees were seen at that time. The coma would have been in place since 10,900 BC and lasted to 4077 BC. The line of text about the blindfolding is, at any rate, a curious statement. But it is also not at all untypical of the *Chilam Balam* to sum up thousands of years in a single sentence.

"Then Oxlahun-ti-ku [Saturn] was seized by Bolon-ti-ku [Jupiter]."

"Then it was that fire descended, then the rope descended, then rocks and trees descended. Then came the beating of (things) with wood and stone."

Jupiter (Bolon-ti-ku, The Nine) is introduced here, but his mention seems out of place (Jupiter appears again a few lines later). It is possible that we are being notified of an agent involved in the sudden nova event of Saturn in 4077 BC. That suggests an earlier electric collision with Jupiter started the mass expulsion and explosive plasma discharge of Saturn, although I doubt it.

- *First the fire, then the rope* -- This is in the correct order. After the extinction of the plasma flow in arc mode, Saturn would have switched to continue the discharge in glow mode -- the "rope." The "rope" will continue into post-Classical times as a symbolic connection to heaven which delivers grace and other celestial dispensations to the Maya. The concept is still in use today among Maya shamans.

I have not made much, in the text of previous pages, of differentiating the extreme arc mode plasma discharge from the glow mode plasma, since there is no indication of how long the arc mode plasma lasted. Both are recorded in the petroglyphic records from remote antiquity, although apparently most, if not all, the petroglyphs are in reference to an earlier south polar column.

- *"Trees and rocks"* -- Here I am again beset by the fact that repeatedly the order of things seems reversed in lines which follow each other. The "trees" is a phenomenon associated with the plasma instabilities during the time of the "descent of fire," that is, a plasma stream in arc mode (but also associated with high-level glow mode). The "rocks" are also likely a plasma stream disturbance but could also be the descent of Mars and his followers during the lowering of "the rope." Of course I am reading these lines as sequential because they appear in the text as one following the other. But a story with an orderly sequence in time was never a strong concern of the Mesoamerican languages. Richard Luxton, in *The Book of Chumayel* (1996), has "sticks" for "trees."
- *"The beating of things with wood and stone"* -- The "wood and stone" appear again later in the text in a description of the rulership of Saturn, and obviously refer to Uranus as the wood and Venus as the stone. Both might be seen as flailing about Saturn if the rotational axis of Earth and Saturn did not line up. Saturn would have been seen revolving (or rocking) in the sky. Vedic sources state that Saturn "rotated without cease." The *Chilam Balam* will address this perambulation later in the text, in a description of Saturn's rulership. What we have here, however, is a description of the visual effect of the rotational axes of the two planets not lining up. The "things" being beaten are the rings which would seem to wobble as seen from Earth. In the *Popol Vuh* the wood and stone are the magical gardening tools of Hunahpu and Xbalanque. [\[note 9\]](#)

In Classical times rulers are shown holding a "Venus scepter" -- a puppet-like head crowned with a jester headdress of three points and with the tail of a snake. The spikes of the headdress were recorded at other times, as in this example, from the Tang dynasty of China:

"On the morning of March 18, [AD] 904, Venus was observed near the Pleiades blazing like fire. The next morning, to observers, Venus appeared to have developed three horns, somewhat resembling a flower, and then began to tremble and shake."

-- Charles Raspil *Planetary observations of the T'ang* (1994)

The three spikes are a cone of plasma extending from the pole of a planet, shaped sort of like a chalice. Only the outer edges of this shape are seen, where the plasma is visually more dense in profile. The third spike is a stream of dense plasma central to this. The plasma flowers will show mainly at the north magnetic pole. The problem with this reading of the "three horns" from the T'ang is that Venus does not today have a magnetic field which would be needed to support such a display. [\[note 10\]](#)

The "wood," is Uranus, seen beside Saturn, and is probably represented by a jade god-face hung by a chain from the rear of the belts of the rulers in Classical times. Notice that many features of the Saturnian Polar Configuration, such as Uranus in this instance, are differently interpreted in different instances in this text, an indication that the scribe may have been looking at illustrations which were not captioned.

The Nine: Jupiter

The next line again introduces Jupiter. Saturn is attacked by Jupiter, so we are now in 3147 BC:

"Then Oxlahun-ti-ku [Saturn] was seized by Bolon-ti-ku [Jupiter]."

This line exactly repeats one of the lines above, which I noted as being out of place. If so, it is an old transcription error.

"Then Oxlahun-ti-ku [Saturn] was seized, his head was wounded, his face was buffeted, he was spit upon, and he was (thrown) on his back as well."

"After that he was despoiled of his insignia and his smut."

About the above text Roys notes:

"Bolon-ti-ku, or Nine Gods, appear to be treated as one god. We find them represented in the inscriptions, and it seems likely that they represent the nine underworlds and correspond to the Nine Lords of the Night of the Mexicans."

"The inscriptions" mentioned by Roys are probably the *Dresden Codex* and other glyphic books which had come to light before 1930. The Nine Gods is Jupiter plus its visible satellites (eight seen before the 20th century AD). [\[note 11\]](#)

Jupiter rises in the east from the Caribbean, sets west in the Pacific, and travels through the sky almost overhead because the Yucatan is at a latitude of 18 to 20 degrees. Jupiter thus seems to travel in a circle over the Earth and underneath. The Maya conceived of the world as floating on water, being aware that they were bordered by the Pacific and almost surrounded by the Caribbean. And they specifically noted water welling up from below in the subterranean limestone caves and surface cenotes. The region below ground became for them the Underworld, as nine levels below ground, each level controlled by one of nine Gods. See also my notes further below on the Absu, the "House of Nine Bushes."

- *"Oxlahun-ti-ku [The Thirteen] was seized"* -- Saturn came into close proximity of Jupiter, 6 to 14 million miles (10 to 23 million km). This actual close contact between Saturn and Jupiter would have lasted very little time. The shock of the electric forces was attractive because of the much greater positive charge of Saturn. This is how Saturn was "seized" by Jupiter. The attractive force would have stopped very quickly with a change in the induced voltages, followed by a charge equalization due to electric arcing, and the separation of the planets. "Seized" also likely describes an extension of plasma as lightning reaching from Jupiter to Saturn.
- *"... his head was wounded, his face was buffeted"* -- This is the initial plasma interaction, probably in large sheets of plasma impinging on Saturn in visible glow mode, or as

contacts in arc mode. Jupiter at this point, moving beyond its original orbit at 0.7 AU, was in need of electrons, but Saturn still had its positive charge and needed electrons even more.

- "... *he was spit upon*" -- As Saturn distanced from Jupiter, the plasma connection initiated by Jupiter would have switched to long-distance plasmoid strikes. It might have looked like spittle, since these would take time to travel through space. Egyptian legends make this image into the sperm of Seth (Jupiter) and Horus (normally Mars, but here probably Saturn). When some of the predynastic "kings" of Egypt take on names like "Crocodile" and "Catfish-Chisel" we are seeing similar interpretations from the other side of the globe. Plasmoid bolts look like catfish or like crocodiles with open jaws.
- "... *he was (thrown) on his back as well.*" -- At first the spectacle would have been viewed in the north skies, since Earth was still below Saturn by some 3 million miles (5 million km), and probably over 4 million miles (6.5 million km) below Jupiter. But as Earth was released to travel its own path around the Sun, the orbit of Earth would be lifted to have the Sun again be one focus of the orbit. At that time the perspective of the two battling planets would have changed and they would have been seen on the ecliptic with Saturn viewed edge-on -- equivalent to having been thrown on his back.

The earliest Egyptian mention of Osiris and the account of his death (Saturn here) is found among the fifth dynasty pyramid texts of Unas (2345 BC), where it is related that Osiris died by falling on his side -- at the river bank. This is not the Nile river, but the river of the ecliptic.

- "*After that he was despoiled of his insignia and his smut.*" -- "Smut" is the face paint used by priests during a period of fast and consecration, Roys notes, although Bolio reads it as plumage, which is perhaps correct, as detailed below.

Roys has extensive footnotes on "the despoiling of the insignia," relating the insignia to "something held in the hand" -- a scepter carried by rulers, in the form of a dragon or manikin with a snake tail. The name of the "canhel" scepter translates as "dragon" or "serpent." "Something held in the hand" is most likely Venus connected to Saturn with a plasma trail. This is the scepter held by Maya rulers. This shows up also on the predynastic tags of grave goods of Egypt as the cudgel wielded to strike enemies. Some writers have simply equated "canhel" to Kukulcan, the plumed serpent Quetzalcoatl. Which is correct.

Bolio translates the line as:

"And their [The Thirteen's] Serpent of Life, with rattlers in its tail, was stolen and with it was taken its quetzal plumage."

The "quetzal plumage" of Bolio comes close to referencing the "insignia" to Quetzalcoatl -- the "feathered serpent" of the Mexicans, known as Kukulcan in Mayan, and identified as Venus. The "Serpent of Life" scepter is Venus, as Schele and Freidel have noted. [\[note 12\]](#)

The Maya purposely avoided any reference to Quetzalcoatl (or Kukulcan) in the *Chilam Balam* books, for the Spanish priests were on the lookout for references to Quetzalcoatl, whom they considered as possibly the chief object of idolatry among the Maya, based on their experience with the Aztecs. Other books of the *Chilam Balam* specifically blame idolatry on the Itza who had moved into the Yucatan 800 years earlier and at some point supposedly brought the worship of Quetzalcoatl from Tula. But Venus (Kukulcan) had already been part of the Maya sacred iconography in Classical times as the Vision Serpent and the double-headed serpent bar. [\[note 13\]](#)

Nine-Lives: Mars

Next, and still in Katun 11-Ahau, we are introduced to "Nine-Lives" -- actually, the first "Nine-Lives." This paragraph is clearly out of place for the text describes events before the close of the "Era of the Gods" in 3147 BC, which termination was related above.

"Then shoots of the yaxum tree were taken. Also Lima beans were taken with crumbled tubercles, hearts of small squash-seeds, large squash-seeds and beans, all crushed."

"He wrapped up the seeds (composing) this first Bolon Dzacab ["Nine-Lives," Mars], and went to the thirteenth heaven."

"Then a mass of maize-dough with the tips of corn-cobs remained here on earth."

"Then its heart departed because of Oxlahun-ti-ku [The Thirteen, Saturn], but they did not know the heart of the tubercle was gone."

Roys translates "Bolon Dzacab" as "nine generations" and suggests it means "forever." Bolio translates "He who is eternal." Fisher's text has a parenthetical insertion which reads, "Yax Bolon Dzacab -- Great Nine-Fertilizer." "He," at any rate, seems to refer to "Nine-Lives," Mars, not some other undefined God. Schele and Freidel also identify Yax Bolon Dzacab as God GII of the Palenque Triad, which is Mars. In footnote 11 to Chapter 2 of *Maya Cosmos*, Freidel and Schele identify (on a somewhat different matter, and as a verb form) "Bolon Tz'acab" as possibly meaning "nine manifested" which makes a lot more sense.

- "... *this first Bolon Dzacab*" -- Without a doubt Nine Lives is Mars. Like Horus of the Egyptians, who is called "the first Horus" when he is listed among the first gods, Mars is here called "this first Bolon Dzacab." He is also called (or implicitly regarded as) "eternal" for he will reappear for ages to come. Although the Sumerians and Egyptians counted repeated visitations of Mars as repeated incarnations, the Maya neglect repeated visits in the record of the *Chilam Balam*, both for the period before and after 3100 BC and for the later 8th and 7th century BC. It is likely that the "nine" of "Bolon Dzacab" should tell us that this event happened nine times -- one more than the Sumerian "kings before the flood." For the Mesoamerican writer there was no reason to tell of repeated

visits of Mars. Additionally, it is perhaps the nine risings up to Saturn which are counted here, not the eight lowerings, as in Sumer. (The *Dynastic Chronicle* from Babylonia lists 9 kings before the flood, however.) [\[note 14\]](#)

- *"Then shoots of the yaxum tree were taken ... etc.,"* -- and other assorted small granular matter. On the one hand, the look of a planet wrapped in squashed beans and seeds would be the look of the lower half of Mars which is pockmarked with craters. But I will suggest another understanding further below.
- *"Then a mass of maize-dough with the tips of corn-cobs remained here on earth."* -- This obviously has reference to the "creation of humans" events recorded in the *Popol Vuh* and other sources, when humans were fashioned by the Gods out of maize dough. Bolio makes it read as, *"And then his [Mars's] skin and the tips of his bones fell here on the land."*

If what is described here records the descent of Mars before 3147 BC, then the "skin and bones" would represent the massive uprising of water in the North Atlantic or the inverted dome of plasma (at the same location) which is featured as a mountain in other creation myths. The Yucatan is located ten degrees further from this site than Mesopotamia or Egypt. The clouds reaching beyond the stratosphere, would easily have looked like a mountain of corn mash. This is also the location of the "Seven Caves," which repeatedly show up in other Mesoamerican creation myths down to the time of the Aztecs (as well as the Incas), where humanity originated. [\[note 15\]](#)

- *"Then its heart departed because of Oxlahun-ti-ku [The Thirteen]."* -- Both translators have the heart of Mars depart for the highest heaven. Bolio has: *"... because the Thirteen gods [Saturn] did not want his heart and seed to be gone from them."* This is the departure of Mars from Earth, and seemingly composed of the image of Mars climbing up the plasma stream in the era before 3147 BC. If this is so, then the "shoots of the yaxum tree, etc.," mentioned above, might also represent nodes in the plasma stream which seem to follow Mars on the returns. This was noted by Talbott at the 2001 conference.

Note that the Mars events described here are out of place. The return of Mars to Saturn happens before 3147 BC, not afterwards. In fact, the visits of Horus which the Egyptians experienced after circa 3050 BC are missing here, although they are described further below.

The close of the drama of 3147 BC is the second battle described by Hesiod. This probably took place within 200 years. The four planets retreating from the inner reaches of the Solar System had to move through the asteroid belt, with the consequence that asteroids were "attacked" with plasma strikes -- with plasmoid bolts by Jupiter, as would be likely under the circumstances of enormous amounts of ionized material and increasing amounts of fine silicate dust in the ecliptic at the location of the asteroid belt -- formed by the plasmoid bolts of Jupiter (and the other three giant planets). Plasmoids can travel millions of miles through space.

"After that the fatherless ones, the miserable ones, and those without husbands were all pierced through; they were alive though they had no hearts. Then they were buried in the sands, in the sea."

Roys notes that two other *Chilam Balam* versions read "fell to pieces" for "pierced through," an expected breakup of asteroids, although it is difficult to imagine how this could have been seen from Earth. Perhaps comas greatly enlarged the sizes of the asteroids. I doubt if the "fatherless ones" might have been asteroids large enough to be distinguished. That too is hard to believe, except that when individually surrounded with a coma they could perhaps be seen from Earth. Alternately it might refer to Saturn, Neptune, and Uranus receding through the asteroid belt.

The "sea" is the whole of the southern sky below the equatorial, identified as the Absu by the Sumerians and the Duat by the Egyptians -- alive with glowing moving concentric wavy rings of particulate matter looking like a sea.

The "sand" (strand) is then the edge of this sea, or the glowing ecliptic, (which dips into the Absu for part of its length). The ecliptic would start to glow as the dust of plasma contacts from Jupiter (and the three other giant planets) started to accumulate. It was yellow like sand and called the "Yellow Road" in China.

"Have you no fear of me?" says the Lord; "will you not shudder before me, before me who made the shimmering sand to bind the sea, a barrier it can never pass? Its waves heave and toss but they are powerless; roar as they may, they cannot pass." -- Jerimiah 5:22

From what God has just said, it looks as if the outer ring of the Absu was yellow or buff colored and understood as a strand -- a barrier between the celestial sea and the sky above it. Both the Bible and the Quran identify the barrier as a strand -- a beach.

"There would be a sudden rush of water when the theft of the insignia of Oxlahun-ti-ku [The Thirteen] occurred."

The narrative has backed up a page. This is the massive worldwide flood which I have placed in the year 3147 BC in the narrative, the flood of Gilgamesh (as I happened to have named it). It would, in any event, happen immediately after Earth was released from the gravitational hold of Saturn. Again we have here, as above, a dislocation of the order of events, as if, as I have suggested, the folio pages of a book were read in the wrong order.

"Then the sky would fall, it would fall down upon the earth, when the four gods, the four Bacabs, were set up, who brought about the destruction of the world."

Here the "fallen sky" is related to the time directly after 3147 BC. I presume that this mention is not more of the "rush of water," but represents what the Olmecs understood as a collapse of

the sky above Earth, perhaps a darkened sky as later recollected from 2193 BC when Akkad and Egypt both collapse economically. This, too, seems out of place.

The four Bacabs are the gods of the cardinal points. They will hold up the sky, and set up four trees holding up the sky. These trees now hold up the dome overhead and the northern stars -- something perhaps never seen before. The following text will also repeatedly note that the four trees are set up as "a sign of the destruction of the world."

The First Four Trees

The text here launches into a description of the four colored trees which are set up at the cardinal points, each surmounted with a bird (of the same color), and also a green central tree. We should welcome this side-trip into geography. Mapping the Earth is a very central element to the Mesoamerican (and American Indian) conception of the world, and as a result we have details not available in other parts of the world. Besides, the "trees" were absolutely huge -- the largest entities ever seen in the skies.

"Then, after the destruction of the world was completed, they placed (a tree) to set up in its order the yellow cock oriole."

"Then the white tree of abundance was set up. A pillar of the sky was set up, a sign of the destruction of the world; that was the white tree of abundance in the north."

"Then the black tree of abundance was set up (in the west) for the black-breasted piçoy to sit upon."

"Then the yellow tree of abundance was set up (in the south), as a symbol of the destruction of the world, for the yellow-breasted piçoy to sit upon, for the yellow cock oriole to sit upon, the yellow timid mut."

"Then the green tree of abundance was set up in the center (of the world) as a record of the destruction of the world."

My first inclination was to suggest that these trees were versions -- real or not -- of the tree seen in the north, connecting Earth with the Saturnian planets. Saturn at the top would look like a bird, for the equatorial outpouring of plasma (the rings) of Saturn (before 3147 BC) might have looked like the plumage of a bird. The ball-shape of Venus connected with a long thin swirl to Saturn (as in the Egyptian "Eye of Ra") could pass as the head of a bird (as could Uranus). Additionally, the plasma connection had been seen as a tree at times -- a discontinuity of the stream with toroids forming at intervals along the stream. These would flatten and the edges would turn up, making the plasma stalk look like a plant, complete with leaves and a circular form at the top like a giant flower. Images of this strange plant are still shown on Sumerian seals of 2350 BC. But these trees are not mythological substitutes --

these trees were real.

When the tree of the north with Saturn on top disappeared after 3147 BC, another stellar bird appeared in its place, the constellation Ursa Major, with the location of the axis of the sky piercing the center of its body.

At a later date the Maya substituted the Milky Way for the "white tree" of the north. The Milky Way rotates through the night sky on a daily basis, starting off at different angles at different seasons, standing as a tree in the sky at the solstices, stretching from north to south horizon (more or less), and is described in Classical times. (See especially the book *Maya Cosmos* by Schele and Freidel.) The Milky Way does not intersect the bird form of Ursa Major, today or at any time in the past.

Others have suggested that these four directional trees are imaginary markers, implicit in the solstitial rising and setting of the Sun, some 25 degrees north and south of the east and west cardinal directions. That would be a ludicrous suggestion if it were not for the fact that creation ceremonies of Maya shamans today use these cardinal points.

However, in previous text I have already presented details of the four trees (under the subject heading of "The Return of the Axis Mundi"). The north and south trees can be described as plasma plumes. These match the descriptions of a bird at the top, as seen here in the *Chilam Balam*, and from illustrations of either a manikin or a ball at the end of the bent-over plume from Mesopotamia and Egypt. These are locations 20 degrees further north, and thus the plumes were even more bent over.

Initially, after 3147 BC, the white tree of the north was probably the most significant as well as the most prominent plasma plume. The first tree of the north is mentioned in the sculptures at Palenque, and held at equal value with the end of the previous epoch, and the appearance of the planetary Gods (their births) 700 years later.

In a footnote Schele and Freidel translate the inscriptions at Palenque for the event of 3112 BC (a year and about six months after the start of the present epoch), of "Wacah chan xaman waxac na GI," to "raised-up-sky north-eight-house GI," but also translate "Wacan chan" as "six-sky." The "raised-up-sky" is based on reading "Wacan chan" as "Wac ah chan." Schele also identifies "raised-up-sky" as the Milky Way. "GI" is Venus, but GI may be a typo for GI-prime.

If "wacan chan" is read as six-sky it would fit the practice in the *Chilam Balam* of prefixing celestial objects with the number of their appearances in 3000 years of history. "Six-sky" would have appeared six times, if the plasma column were to be generated with the six known changes in the Earth's orbit (3147 BC, 2349 BC, 2193 BC, 1492 BC, 747 BC, and 686 BC). But add the change in the electric field of the Sun of 685 BC, and there are seven. Or add the possibility of two additional, but unnoted, changes between 2349 BC and 2193 BC, and there are 8 instances again, justifying a reading of "north-eight-house." North, as

opposed to south, is a clear indication that we are here dealing with one of the two polar plasma plumes. This last is also better supported by the name given to the north tree at the ballcourt markers at Copan -- "Nine Successions." [\[note 16\]](#)

The "raised-up-sky" "north-eight-house" (also called "edifice") of Venus (GI) was dedicated a year and a half after the start of the current era, as retrocalculated by the Maya. It is within expectations that it would take perhaps a year to develop a plasma stream in glow mode in response to a change in the electric field surrounding the Earth's plasmasphere. The event is noted here (and in other records) because the raised-up-sky north-eight-house must have been much larger than anything else ever seen in the skies up to this point in time. It rose far above the previous polar location of Saturn. Seen from Mesoamerica, the Saturnian planets had hovered only some 20 degrees above the north horizon. "Saturn entered the sky," is noted because the planet had now moved (within a year and 9 months) across the sky and to the south. This had to be established first (in the Palenque text) because otherwise Saturn (God GI-prime of Palenque) would not have been able to construct his edifice. [\[note 17\]](#)

The Green Tree of the Center

About the tree which "was set up in the center," Roys writes, "This last tree was remembered by the Maya." The green celestial tree is the massive outpouring of plasma from the south pole of Jupiter, which I have noted in earlier texts. This was seen directly after 3147 BC, and again twice after Jupiter had passed through the asteroid belt, although at these later times the "mountain" had turned red. There is a fourth appearance in 685 BC. Note that "green" is not one of the directional colors of the Maya. This "tree" is not located at one of the cardinal points.

Initially the green tree of Jupiter with its lower plasma outpouring was seen between 3147 BC and 2880 BC, before Jupiter entered the asteroid belt. The mountain was topped by two owl-like eyes peering out from the top of the head of the coma, and a beak-like form below it. These were recorded in profusion at this time -- carved on the interior walls of barrows, as petroglyphs, and carved as amulets. Also notice that the green tree did not include a bird.

"Peratt ... identified the 'eye mask' as a 'low opacity torus' or thick ring, seen from a vantage point substantially off-axis, not too far from the plane of the torus."

-- Talbott and Thornhill, *Thunderbolts of the Gods* (2004)

In the first hundred years or so after 3147 BC, the planet Jupiter is here the green tree of the center, whereas in later text Jupiter and its lower plasma expulsion are specifically noted as being red. Both the green and red colors can be generated by excited hydrogen ions at diffuse densities.

In Egyptian funeral imagery Osiris is almost always shown as a mummy wrapped in green.

In early Egyptian iconography, and in phrases recorded in the Egyptian *Book of the Dead*, Jupiter is identified as Osiris (since the fifth dynasty).

Jupiter's green lower plasma expulsion is designated as the "tree of the center" because it was first seen in the east, and then moved, over the course of some months (in addition to nightly), past the south to diminish again in the west. The tree was obviously "in front of" the trees of the east, south, and west -- which did not move through the night or over the seasons. It was the brightness of Jupiter's coma that convincingly made it look as if it moved "in front of" the other trees.

The image of a tree of the center will reappear in later Olmec iconography, as seen at La Venta (circa 650 BC). There Jupiter, which developed another plasma outpouring in 685 BC, will be shown with a headdress of three flower-like petals, and legs composed of the open jaws of a crocodile. The crocodile form is the much more extensive plasma at the south pole of Jupiter (which is its north magnetic pole).

In much later Classical-era Maya imagery the "tree of the center" (at that time represented by the Milky Way) is frequently transformed into an upended crocodile with its jaws at the bottom and with branches at the top sprouting from its tail.

The East and West Trees

The east and west trees are very likely the toroidal belt of trapped particles (the Van Allen Belt) above the Earth's equatorial. Viewed directly overhead this would be nearly invisible because the toroidal Van Allen belt surrounding the Earth would be viewed as larger and more diffuse -- it would disappear. Seen toward the east or west, it would be much more substantial. In the east and west the edges of the toroid would be seen to rise up from the horizon, as two parallel lines or a uniformly flat strip, with a circle shape at the top, looking not unlike the ball plasmoids at the ends of the polar plumes -- but without the three-pronged extensions. The east and west trees also did not move.

At the latitude of the Yucatan these would rise almost straight up into the sky. The repeated phrase of the text, "*set up as a record of the destruction of the world*," suggests, however, that the trees appeared suddenly. This would certainly be true for the polar plumes, which would switch from dark mode to glow mode suddenly. This also suggests that the toroidal Van Allen belt also was in glow mode.

It is possible to take a hint that this might be so from Egyptian sources, as from an illustration of the *Book of the Dead*, where four lights or plumes with the required bent-over shape are carried by four persons. There is also a glyph, known as "Khet," depicting a bent-over plume coming out of the top of a form which is otherwise identified as a lamp or brazier. [\[note 18\]](#)

Implicit in the imagery of the four trees at the cardinal points is the fact that they were

established to hold up the dome of the sky and the stars. They (or the four Bacab Gods responsible for the cardinal points) last without harm through various destructions of the world.

The four trees were represented in Maya temples before the start of the Classical era in AD 300 or 400 as actual tree trunks socketed into the upper platform of temples (as at Cerros before 50 BC). At the close of the Classical era, in AD 900, these had been replaced by stelae (**te-tun** -- tree stones), then associated with the commemoration of the passage of time and with the celebration of various rulers.

By the time of the Spanish invasion the trees signify the geographical division of the land into four quadrants, and define the local domain of individual rulers. The trees also came to represent the winds from the four directions. The Gods of the four trees are all named after the God of rain, Chac. These Gods held up the sky in the form of an altar. Maya shamans today still construct these altar tables in "creation ceremonies." The imagery dates from the Olmec era, where gods appeared out of a cave set below the edge of the 6-foot-high stone tables. The cave will be recognized as the dark doorway which normally appeared nightly against the equatorial rings. Although this had not happened since 2349 BC, the imagery remained to show up on altars at San Lorenzo. That the sky is intended with the table-like altars is obvious from the typical Olmec "sky monster" glyphs appearing at the top edge of some of the altars.

At Potrero Nuevo near San Lorenzo, two dwarfs hold up the altar like atlantes. The table edge is carved with cloud glyphs.

A listing of the directional trees, or the colors of the cardinal directions, occurs three times in the text. Each happens (as we shall see below) at a new creation, signifying a radical change in the skies, or a renewed sky.

Mesoamerica uniformly professed a belief in four creations, called "suns," except for the Aztecs who counted their own arrival at the Central Mexican plateau as the fifth creation. If the "creations" are equated with the appearance of the Sun, or a renewed Sun, then the "first creation" started in 10,900 BC, as the creation of the southern ball plasmoids, the "second creation" is the following period, ending in 3147 BC, and the "third creation" ends in 2349 BC, and a fourth may have been attributed to the 1492 BC. (This assumes the "creation" periods are consecutive.)

I am suggesting 1492 BC because it is the third time the trees show up. The cardinal direction trees and colors are invoked three times in the *Chilam Balam*, each time when a new sky is established, after 3147 BC, after 2349 BC, and after 1492 BC. I will return to the question of ages and eras below.

This concludes the events of Katun 11-Ahau. I don't doubt the veracity of these sources, even though presented in somewhat disorderly fashion, and describing events much older than the

earliest recognized archaeology of the Maya or the Olmecs. This is not unexpected, since, as recounted (or hinted at) in the *Popol Vuh*, individual tribes acquired their own copies of the history books which had been kept at certain important sites.

In the text of the following Katuns additional details are developed, which again, with some extension of the strange names we are presented with, can be matched to worldwide catastrophic events we know from other sources. But the following events are more difficult to sort out. Whereas events before the start of the current era (3147 BC) are all listed as happening in Katun 11-Ahau, the text which follows reads as if events separated by a thousand years or more are simply listed by the Katuns during which they might have occurred -- Katun 9-Ahau, 7-Ahau, 5-Ahau, and 3-Ahau. Following these are two sections separately describing the rulership of Saturn and Jupiter.

Katun 9-Ahau: Ten-Sky

The next Katun in order, Katun 9-Ahau, is introduced. This is the next Katun in order only if we adhere to the logic that Katun 9-Ahau is the next after Katun 11-Ahau. The period before 3147 BC does not end in a Katun 11-Ahau, but in Katun 4-Ahau. Philosophically, however, the Maya could only place "prehistory" in Katun 11-Ahau (Since a Katun 11-Ahau had ended on February 28th, 747 BC.)

By coincidence, Katun 9-Ahau is actually the fourth Katun after 3114 BC (four times 20 years: Katun 2-Ahau, 13, 11, 9), thus completing the 80 years of "negotiation" which the Egyptians claim as the delay before Horus/Mars takes control of Egypt. Counting 80 solar years forward (as Katuns) from the date of 3147 BC, reaches 3067 BC as the ending date of Katun 9-Ahau. This is also the most likely date when Mars first shows up in Egypt.

"The plate of another Katun was set up and fixed in its place by the messengers of their lord."

The "plate" is often used to reference a Katun together with "cup," as in, "nine was its cup, nine was its plate," used to describe Katun 9-Ahau, and similar readings in the "Chilam Balam" for other Katuns. Tedlock reads "plate and cup" as the dedicatory vessels used at shrines.

At this point the four trees of the cardinal points are introduced again. I don't know why. We have just seen the trees that appeared right after 3147 BC. The trees are here out of order, and very likely the source pages are being read out of order. This second set of trees has to follow rather than precede the notes about Venus (Ah Uuc Chek-nal, further below, after my notes on Ten-Sky).

"The red Piltec was set at the east of the world to conduct people to his lord."

"The white Piltec was set at the north of the world to conduct people to his lord."

"Lahun Chaan was set (at the west) to bring things to his lord."

"The yellow Piltec was set (at the south) to bring things to his lord."

In the third line quoted above, "Lahun Chaan" (Ten-Sky) is not one of the colored trees of the cardinal points, but is Mars. So thinks Roys, who writes, in a footnote on this matter:

"Lahun Chaan is doubtless the same as the 'Lahunchan' described by Cogolludo as an idol with very ugly teeth. 'Lahun' means ten in both Maya and Chol, and 'chan' means sky, heaven, and serpent in Chol. The Maya word for sky is 'chaan'."

He continues at length, and adds:

"We recall that a fleshless jawbone is one of the symbols of the number ten on the monuments; but the figure appears to be the regent of the second Venus period in the Dresden Codex, and the regent of the first of these periods in the Mexican Codex Bologna also has a fleshless lower jaw. Since the above passage in the Chumayel implies that Lahun Chaan was set in the west, the translator is inclined to believe that this god was closely connected with the appearance of Venus as an evening star."

I doubt that "Ten-Sky " is a reference to Venus, for Venus is seen both in the east and in the west as well as traversing the whole of the sky during the day, as Roys's insertion suggests. Mars is seen crossing the night sky. The phrase "at the west" is, however, an insertion based on the fact that a tree of the west is not mentioned. The line actually reads, without the addition by Roys:

"Lahun Chaan was set to bring things to his lord."

I think "Ten-Sky" is Mars. We see nothing else of the repeated close calls by Mars during the period of about 3100 BC to about 2700 BC except the title "Ten-Sky." From Egyptian and Mesopotamian records it appears that Mars/Horus cruised close to Earth some ten times after 3100 BC. My estimate for the first appearance of Mars/Horus is the year 3067 BC. The Katun 9-Ahau period -- when "Ten-Sky" first appeared -- ends in the corrected date of 3067 BC.

To "bring things to his lord" is mentioned for all four (or three) trees here, but not for the other instances of these trees elsewhere in the document. The question then is, Who is the "lord"? Since we know already that during the first 150 to 300 years when Mars drew close to Earth, Jupiter stood in the sky as a globe on top of a green mountain, after which it entered the Asteroid Belt (and the mountain form disappeared), it is likely that the "lord" is Jupiter. His reign is attested to elsewhere (as the "second reign"), but here (for this Katun) there is no other mention of Jupiter.

In the *Popol Vuh* the celestial twins Hunahpu and Xbalanque defeat the mountain giant Zipacna directly after they remove the Celestial Bird of the North Pole. Mars, known as Earthquake in the *Popol Vuh*, is their third target. He will be tricked, drugged, hog tied, and buried alive.

Katun 7-Ahau: Venus

The next lines are without question about Venus. Since no notice of a change in Katuns is given, this should be a continuation of Katun 9-Ahau, which dealt with Ten-sky. But instead the record now jumps 2000 years ahead to a Katun 7-Ahau which ends in 1478 BC, and spans 1507 BC to 1487 BC in corrected notation. This thus spans 1492 BC, the electric

contact by Venus (and the Exodus). This arbitrary grouping of events by Katun names, even when they are not really consecutive, is typical of the other books of the *Chilam Balam*. The *Chilam Balam* continues:

"But it was (over) the whole world that Ah Uuc Chek-nal was set up. He came from the seventh stratum of the earth, when he came to fecundate Itzam-kab-ain [the Earth], when he came with the vitality of the angle between earth (and) heaven."

Roys translates "Ah Uuc Chek-nal" as "he who fertilizes the maize seven times," which suggests that "Ah Uuc Chek-nal" appeared seven times. I suspect "Ah Uuc Chek-nal" is Venus.

"Itzam-kab-ain" is the Earth, the whole Earth, designated as a "crocodile-footed whale." The Maya conceived of the Earth as floating on water, and as supported by a giant whale-crocodile creature. Bolio translates this passage as:

"At that moment, Uuc-chek-nal came from the seventh layer of the sky. When he came down, he trodded on the backs of Itzeam-cab-Aim, so-called. He came while the earth and sky were being cleaned."

The imagery is not far removed from a "close passage" of Venus, except that Venus would never have come close. The phrase "while the earth and sky were being cleaned" suggests hurricanes and tsunamis, which would certainly have been experienced on the four or more approaches by Venus between 2349 and 2193 BC and again in 1492 and 1442 BC. The first approach (2349 BC) involved the fall of the Absu -- the "flood of Noah" -- but this is handled separately and out of proper sequence further below.

If this, as I suspect, represents the contact of 1492 BC, the compressive contact would have been in the Pacific, and immense amounts of water vapor would have been carried into the atmosphere. The path of arcing would have angled up (because of the Earth's gyroscopic reaction), swung through the Indian Ocean, the Mediterranean, and angled southwest again through the Atlantic. The experience of Mesoamerica would have been two-fold, first a Pacific tsunami from the west, followed by billowing clouds from the west, the last arriving less than a day later. Attributing these to a celestial interloper is fully within the realm of what other people did. The planet was seen -- as if approaching -- and the local effects were interpreted as if Venus were close by.

Roys suggests another translation of *"when he came with the vitality of the angle between earth and heaven,"* which reads, *"then he descended while the heavens rubbed against the earth."* That makes sense as the condition of a fallen sky after 1492 BC. But, in fact, it makes more sense in that the "rubbing" would represent the huge shape seen in the night and day skies, the inner Van Allen belt toroid in glow mode, seen more or less in the center of the sky, on both sides of the equatorial, and stretching from the east horizon to the west.

Now about Katun 9-Ahau and the reason for placing this event in Katun 7-Ahau: Elsewhere I have assumed that approaches by Venus happened repeatedly between 2349 BC (the "flood of Noah") and 2193 BC (the fall of Akkad), for a total of four contacts. Earlier occurrences of Katun 9-Ahau do not match these dates. Katun 9-Ahau in Baktun 1 ends in 2523 BC (corrected to 2547 BC), too early for the "flood of Noah" by 200 years, and Katun 9-Ahau in Baktun 2 ends in 2266 BC (corrected to 2287 BC), after the "flood of Noah" by one hundred years.

I have assumed in these few paragraphs that this event might have happened in Katun 9-Ahau, it is because nothing in the text signifies that a Katun of a different name is under discussion. Katun 9-Ahau in Baktun 4 ends in 1507 BC, when corrections are applied, and thus only comes close to the time of the Exodus of 1492 BC (or other estimates from 1495 to 1491 BC). That would place the Exodus of 1492 BC 15 years after the end of the Katun.

I think, in fact (and as I have pointed out earlier), that this rubbing of Earth and heaven did not occur in Katun 9-Ahau, but happened in the next Katun, 7-Ahau, even though the text is silent about this. There is a pattern developed in the text of assigning appearances of planets to Katun 9-Ahau, at times by inference and at times by the neglect of naming the actual Katun. This becomes obvious when it is realized that the event of 2349 BC (the "third creation") is assigned to a Katun 9-Ahau in complete error, as I will describe further below.

This then is what we have: Since all of pre-history is assigned to a Katun 11-Ahau, the start of the current era (from 3147 BC) is assigned to the assumed first Katun of the era, 9-Ahau. This despite the fact that the current era started with Katun 2-Ahau. But the next event, the ten close passages of Mars (Ten-Sky) are then correctly assigned to Katun 9-Ahau, and the Katun is named. The next event, the electric contact of Venus in 1492 BC, is, however, assigned to the same Katun 9-Ahau only by the fact that no mention is made of a new Katun. The text shifts to this event as if it belonged to Katun 9-Ahau. But, in fact, the corrected ending date for Katun 9-Ahau in Baktun 4 is 1507 BC -- too early for an event in 1492 BC. The next Katun in order, Katun 7-Ahau of Baktun 4, spans the date of 1492 BC, plus any of the variations of this date as calculated in antiquity -- 1491 BC, 1495 BC.

Now it is possible that the scribe making the transcription simply neglected to mention that the event, "Ah Uuc Chek-Nal rubs the earth," occurred in Katun 7-Ahau. But it is significant that the shift of events to Katun 9-Ahau happens 4 times, one by an implication, two by neglect, and one as a purposeful falsification. This last, the Katun year for the "third creation" stands out, for it involved moving the event so that the "first day of Kan" of the Katun would fall on the Gregorian equivalent calendar date of July 26th. Only Katun 9-Ahau of Baktun 1 does this in all of the 5200 years of the 13-Baktun cycle of time. This trick will be detailed further below.

I have to make note again of the fact that, because of the Maya understanding of the cyclical nature of time, repeated appearances of visiting planets are not separately listed, except in their titles, as in "Nine-Lives," "Ten Skies," and "He Who Fertilizes the Maize Seven Times."

That would seem to explain why there is no notice of Venus between 2349 and 2293 BC. The other events of this same period are listed separately further below.

To return to the seven appearances of "Ah Uuc Chek-nal," I count four appearances of Venus between 2349 BC and 2193 BC, and 700 years later one each in 1492 BC and 1442 BC. This adds up to six overflights. It is possible that the nova event of Venus in 685 BC, another 755 years later, represented the seventh. But this last event is not attributed to Venus in the *Chilam Balam*. Only mention is made of the Sun going off course in 685 BC (further below). I think, however, that all references to Venus in 685 BC, when Quetzalcoatl lived and died, were carefully avoided in the record -- for fear of revealing information to the Spanish priests.

The other likely explanation is that the "cow" form associated with Venus, the change of the Van Allen Belt to glow mode, appeared also directly after 3147 BC, since at that time the Earth would have switched to experiencing the electric field of the Sun from the prior experience of only sensing the electric field of Saturn (being within the plasmasphere of Saturn). This initial event was not associated with an actual electric contact by Venus, except by inference. Since all of pre-history was held to happen in a Katun 11-Ahau, this first cow would have been assigned to the next Katun, 9-Ahau. It is possible that Earth was jolted by Venus directly after 3147 BC. This would constitute the seventh contact with Venus, and might explain why (apparently) the year changed from 225 days to 240 days in 3147 BC. [\[note 19\]](#)

The *Chilam Balam* continues with how the people walked in darkness:

"They moved among the four lights, among the four layers of the stars. The world was not lighted; there was neither day nor night nor moon. Then they perceived that the world was being created. Then creation dawned upon the world."

"They" probably refers to the people, but could also refer to the Gods. That they (the people) "moved" may suggest a migration, as is likely under the conditions of the climatic downturn of 1492 BC. The whole of the paragraph seems almost lifted from the Bible -- speaking of the wanderings of Israel in the desert after 1492 BC.

The "four lights" might be the great luminaries -- the Sun, Moon, Jupiter, and Saturn, although the same paragraph reads that there was no Moon yet. In 1492 BC there was a Moon. Roys suggests "candles" also for the "lights." That suggests stationary lights. Bolio uses "the fourth fire" for the "four lights." I think that the "four lights" are the four "trees" at the cardinal points, the two impinging plasma plumes at the poles and the edges of the equatorial toroid of the Van Allen belt. If a cloud cover obscured the Sun and the stars, as seems implied, then perhaps we are seeing the north and south plasma plumes at least in glow mode, possibly in arc mode near Earth. That might then be true for the east and west plumes also, if these are associated with the toroidal Van Allen belt. This also suggests that the plumes may have lasted for decades.

I also should not neglect that in 1492 BC the Earth went through a wild swing -- it all but tipped over, or at least was placed on its side, as I have suggested in earlier text. Midrashim commentary on Exodus suggests that in 1492 BC the sweep of the pole, "when the stars stopped moving," took a little over a year (Velikovsky). But the major effect is more likely due to a very dense cloud cover, although it is difficult to imagine that a cloud cover (unlike stratospheric dust) would extend to twenty years and obscures the stars.

The use of "the four lights," even if meant to signify the directional trees, might thus be a simile for wandering over a wide geographical area. The language in this case, especially when the following line is considered, which suggests an enormous time span of 8000 years, seems lifted from Book 11 of the *Chilam Balam* which relates the time leading up to the "first creation."

"During the creation thirteen infinite [400] series (added) to seven was the count of the creation of the world. Then a new world dawned for them."

The word translated as "series" can also mean "steps." The "seven" might be the count of the Katun (chronologically). "Infinite" is often the translation of "400," a Baktun. 13 Baktuns would be 5200 years. 13 plus seven would be 8000 year. Thus the "infinite series of steps" might represent a very long time.

On the other hand, thirteen plus seven is 20 years -- one Katun. Other Mesoamerican sources speak to "a generation" of darkness. Bolio translates as:

"Infinite rungs of the ladder of time and seven moons later were counted since Earth woke up and then the dawn came for them."

Seven moons would represent a half year. Most of this phrasing remains unclear except to suggesting the passage of a lot of time, or, as I have suggested, some twenty years. But that could have been stated in terser terms. Perhaps we are here seeing a poetic metaphor for "long time."

It might be suggested, in fact, that the "rungs of the ladder of time" is a metaphor for Uinal months, periods of 20 days. Then we have $(400 \times 20 + 7 \times 20) / 365 = 22.3$ years roughly the duration of one Katun.

The 2349 BC Event

The following, although grouped with the start of a new creation, is, I suspect, from a different source. It details events of 2349 BC, the time of Noah, but not all of them. Some are listed further down in the text. The events are also not introduced by listing a Katun name. We would have to assume that Katun 9-Ahau continues.

I think, from the following text, that the copyist is opening a new book, perhaps one titled

"the third creation." Unlike before, he copies the pages in the correct order, but leaves off the fall of the Absu, which is recounted much later.

The information is, in fact, not out of "literary" order, since the previous text ended with mention of the start of a new creation, although the reference was to 1492 BC. (We see this sort of connection used much later to describe events of the 8th century BC.) The "third creation," however, points to events in 2349 BC. All the events listed over the next few paragraphs belong to 2349 BC, not 1492 BC.

The text starts with:

"The two-day throne was declared, the three-day throne."

The phrase "two-day throne, three-day throne" is used elsewhere in the *Chilam Balam* to denote short-term leadership, especially in reference to the governing councils of the Itza. Bolio, however, has a more sensible reading:

"the reign of the second period, the reign of the third period was felt."

That makes a lot more sense. The alliteration of the text makes it look like a chapter heading. The question again is, where are we in the Katun counts? They are not mentioned in the following texts. We could assume that the text simply continues with the next Katun in order (Katun 7-Ahau or 5-Ahau), but this results in events which cannot be placed at dates known from other sources. I will therefore suggest that the listing of events continues to be assigned to a Katun 9-Ahau, as had been implied for the event of 1492 BC.

But of course this is incorrect, although it continues the obsession of placing all planetary events in Katuns named 9-Ahau. The "third reign" started at 3147 BC, and ended in 2349 BC. This is not Katun 9-Ahau (see listing at endnote 29). There is a reason for insisting that we are still in Katun 9-Ahau. As I will detail further below, the Katun name for the event was changed in antiquity to conform to the notion that the events involving the "third creation" had to have happened on a "day of Kan." This was an important aspect in later analysis of older texts. It was an important notion because it was apparently held that the Tzolkin calendar governed celestial events, rather than the other way around. The "third creation" was the most important event of the past, celebrated with ballcourts and site names, and therefore had to end on the correct day.

There are five events listed before we return to naming Katuns. These are the plasma mountain of Jupiter (which may presumably be correctly dated to an earlier Katun 9-Ahau ending in 2547 BC), the return of a coma of Jupiter (which happened in 2349 BC), the first view of the "planted timber," the appearance of the Moon (in 2349 BC or soon after), and the complete extinction of Jupiter (199 years later). I have listed some of the above in correct order, rather than as the events are listed in the *Chilam Balam*. Some of the events fall in even numbered Katuns, mention of which is avoided throughout the book of the *Chilam*

Balam.

There may still be a question if this represents the "second creation" or the "third creation," because we are, in fact, first presented with what seems to be an element of the second reign. Saturn, the *Chilam Balam* reads, develops a cometary coma. I think there is an error here.

"Then began the weeping of Oxlahun-ti-ku [Saturn]. They wept in this reign. The reign became red; the mat became red; (because of them) the first tree of the world was rooted fast."

Bolio has, instead of "rooted":

"... the tree became red."

And Bolio also has:

"And then the three gods began to cry."

The "three gods" would have been Jupiter, Mars, and Venus. These are the "three gods" of the Classical era of the Maya. Roys, however, only has Saturn (not one of the "three gods" above) crying, which perhaps makes more sense. The "three" of the "three gods" could be a misreading of the "three" of "the thirteen" by Bolio. "Crying" is a plasma discharge -- a coma and tail. Saturn, however, never had a tail -- it is too positively charged.

I wonder if what we read here is a transcription error, that is, the author meant to write that "Bolon-ti-ku," that is, Jupiter, developed a coma and a sub polar tail (started weeping) rather than "Oxlahun-ti-ku," Saturn. We have no record of either Saturn or Mars ever developing a tail, even when Saturn was "attacked" by Jupiter in 3147 BC. I don't think that Saturn is meant above. Saturn by this time had receded into insignificance.

The (corrected) date of 2567 to 2547 BC for the Katun 9-Ahau (in Baktun 1), mentioned above, coincides with the time when the Egyptian pharaohs first add "Re" to their names -- after 2600 BC. "Re" is the midnight sun, Jupiter. I will suggest that this is what is being described here with the "tree turning red."

Thus in this instance, the supposition that we are in a Katun 9-Ahau is correct. This is a record of the re-appearance of the plasma discharge of Jupiter after it had cleared the asteroid belt in receding from the Sun -- about 500 years after 3147 BC. My earlier diagrammatic estimate of when Jupiter first exited from the asteroid belt (shown in a previous chapter) is the year 2527 BC, which is 20 years after the end of this Katun 9-Ahau (2567 to 2547 BC, corrected). Since the dates of the graph are estimates, it is certainly close enough.

The redness of the apparition cannot be neglected. Although Mesopotamian sources do not mention colors, the Egyptians always depicted Jupiter as a huge red ball. This huge red coma

lasted for about 300 years, from about 2550 BC (Katun 9-Ahau in Baktun 1) to sometime before 2349 BC and then returned in 2349 BC. The interruptions will be noted in the text.

The "tree," which Bolio translates as a "red tree," is probably what Mesopotamian cultures had identified as a mountain. It is the plasma discharge of Jupiter from its southern polar region. Notice that the plasma expulsion has changed from green to red. This could mark a change in the ionized gases at the outer edges of the plasmasphere, but it could as likely be a change in the density of these ions. This last is more than likely with a change in the experience of a lower value of the external (solar) electric field.

What the Egyptians called a mountain, the Olmecs identified as a tree. It was earlier identified as the "green tree" of the center. This green mountain described as a "tree" first appeared directly after 3147 BC, but disappeared after 300 years as Jupiter entered the asteroid belt, to reappear 330 years later, as described above.

The Moon

At the following part of the text we still seem to be in the time after the end of the "third creation," the period after 2349 BC. But again, a Katun name is not disclosed. It suggests that we are to understand that events of some named Katun 9-Ahau continue to be listed. The following text is about the Moon, and reports that Jupiter was not weeping. The *Chilam Balam* reads:

"The entire world was proclaimed by Uuc-yol-zip; but it was not at the time of this reign that Bolon-ti-ku [Jupiter] wept."

There is no indication, from the translators, of who "Uuc-yol-zip" is. I would take a wild guess and suggest that, if we are chronologically in the period after 2349 BC, that Uuc-yol-zip is the Moon, which was an independent inner planet already orbiting the Sun at the location to which the Earth moved in 2349 BC. (Lunar calendars are established worldwide only after 2349 BC.)

Earth suddenly picked up a satellite, or, more properly, started to share an orbital location with the Moon, for the Moon travels in the ecliptic, not on the Earth's equatorial. A rapid discharge of the Earth via the Moon, could have destroyed any of the remaining Absu in record time. More on that below.

Uuc-yol-zip is never mentioned again and remains unidentified. Roys, on the basis of other informants, suggests a Deer God, which makes some sense if you have never seen the Moon before and you are suddenly confronted by its changing shape and nightly relocations. The Moon will relocate from the southeast sky to the northeast in the course of a week. But what Katun are we in?

The first appearance of the Moon (the Deer God) should be placed after 2349 BC, but this date falls in a Katun 4-Ahau, rather than the implied Katun 9-Ahau. In fact, I should point out another source, the only other Maya source of ancient history other than the *Popol Vuh*. The Temples of the Cross at Palenque (built in circa AD 690) claims that Jupiter, Mars, and Venus were all born in 2360 BC (corrected to 2336.8 BC a decade after 2349 BC). The Moon was their mother. Later, the Moon "let blood" in 2302.3 BC and "crowns herself" as ruler ("Ahau") in 2282.6 BC. These last two are corrected dates. [\[note 20\]](#)

We don't know exactly what these last two events were. But they can be placed, the first ("letting blood") in Katun 11-Ahau (ending in 2286 BC, corrected to 2307 BC), and the second event ("crowning herself") in Katun 9-Ahau (ending in 2266 BC, corrected to 2287 BC). Perhaps the second Palenque event records the regularization of the Moon's orbit. The wording of "*the entire world was proclaimed*" suggests the same assumption of rulership, which was as deep a concern of the Maya as it seemed to have been for most civilizations in the world. I would thus suggest that the event quoted from the *Chilam Balam* above should probably be assigned to Katun 9-Ahau, and equated to the Palenque record of the Moon "crowning herself" as ruler. This would place it in Katun 9-Ahau (a Long Count of 2.3.0.0.0), even though this is later than what I think it should be. The following will elucidate where this concern comes from.

That Jupiter did not "weep" at the time the Moon appeared (or assumed rulership) is interesting. It suggests that Jupiter had lost its coma and tail. I know that this happened some time after 2400 BC, but I have been unable to determine exactly when. I'll attempt to zero in on that first.

In my diagram of the recession of Jupiter from the Sun, the date when Jupiter encounters the last clump of asteroids at 3.9 to 4.0 AU is shown as 2438 BC to 2349 BC. This may be a high date because I have used a constant radial recession for the calculation.

In Egypt the title "Son of Re" had been in use already by the pharaohs who completed the Giza pyramids before 2500 BC, and was used by all the following pharaohs. During the following fifth dynasty, which spans 2490 BC to 2350 BC, "sun-temples" were built (or rebuilt) along with the pyramid graves of the first six pharaohs of that dynasty, in the period of 2490 BC to 2445 BC. "Sun-temples" are steep pyramids on a flat base. In Egypt these pyramids are the "symbol" of Re, Jupiter, representing the mountain form of the plasma outpouring below its south pole.

Further construction of "sun-temples" was abandoned before the end of the fifth dynasty. These dates suggest that the coma and tail of Jupiter (Re) might have disappeared by 2445 BC (the last "sun-temple"), but we do not know exactly when, or how long it took before this showed up as a change in religious monuments. On the basis of the above information the loss of a coma would be placed sometime before 2445 BC. There is thus a 20-year period where Jupiter seems to have disappeared or, more properly, diminished considerably in size.

The Chinese *Annals of Shu* speak of Yao (Jupiter) gaining the throne as "emperor" in 2357 BC, as if to say that Jupiter again developed a coma at that time. The first few dates of the *Annals of Shu* should probably be placed about a decade later, thus the above date should probably be nearer to 2349 BC.

There is also an interesting passage in the Babylonian *Enuma Elish* which recalls the disappearance of Jupiter's coma tail (as a garment) and its reappearance. Since the *Enuma Elish* clearly recounts the contact with the plasmoid from Venus in 2349 BC, it could be suggested that the disappearance of the coma and tail of Jupiter should be placed before 2349 BC. A period longer than 20 years would perhaps not allow this disappearance event to pass into a narrative. But an exact measure of time was not needed to be recalled, since the *Enuma Elish* was written 500 or 600 years after the events of 2349 BC.

The second instance of the coma of Jupiter disappearing during this time might have coincided with the first appearance of the Moon (at that time perhaps not yet in orbit around Earth). From Palenque, that would be the corrected date of 2336.8 BC (when the planets were "born") -- and thus 12 years after the spectacular blazing of 2349 BC, when Jupiter developed its large coma. But other records contradict this. The *Annals of Shu* claim that Jupiter (Yao) and the Moon (Shun) shared the throne for 30 years. The victory stele of Naram-Sin, "Beloved of the Moon" (2254 - 2218 BC), the great-grandson of Sargon, erected in 2250 or 2200 BC shows the two Gods at the top as stars. Jupiter is shown on his mountain; the Moon is without a support.

Jupiter Returns

"Then came the counting of the mat in its order."

The "counting of the mat" is the start of a new Katun. This has to be Katun 5-Ahau, if the Katuns are taken in order, that is, as if this text is a recital of prophecies associated with various named Katuns. But the naming of Katun 7-Ahau has been skipped, perhaps by accident, perhaps on purpose. The present Katun starts with the seating of Jupiter.

"Red was the mat on which Bolon-ti-ku [Jupiter] sat. His buttock is sharply rounded, as he sits on his mat."

Now we have another plasma outpouring of Jupiter, and again without a clear reference to what Katun has turned. I am tempted to believe that this is the **return** of a coma and tail in 2349 BC. That would place this event in Katun 2-Ahau, at 2.0.0.0.0 in the Long Count.

But it is more tempting to place this event (which seems to have been important for its redness) in a Katun 9-Ahau at the time when Jupiter first exited from the asteroid belt. I have already mentioned this event, above. The red mountain had not been seen for 300 years. This would be a Katun 9-Ahau in the first Baktun (1.10.0.0.0), with a corrected span of dates of

2567 to 2547 BC.

Roys suggests that "his buttock is sharply rounded" could also mean pointed or rounded like a hat. I do not know what to make of this except that it would perhaps fit the emblem -- a circle above a horizontal line -- used for Jupiter (Marduk) in Mesopotamia, and one of the magic symbols of the Egyptians, called the "shen," where the circular part is rendered in red. In Egypt Re (Jupiter) is always shown as a large solid red disk. A "sharply rounded buttock" does not readily match a giant lower plasma stream.

"Then descended greed from the heart of the sky, greed for power, greed for rule."

The phrase, *"Then descended greed from the heart of the sky, greed for power, greed for rule"* exactly expresses the earlier parallel experience after 2700 or 2600 BC in Mesopotamia (the kingship at Uruk) and Egypt (the third dynasty which starts the Old Kingdom). It was coincident (within a hundred years) in both cases with the return appearance of Jupiter on his mountain.

It is also the period after Mars had stopped making close calls to Earth. It is possible that both in the Eastern Mediterranean and in Mesoamerica a change happened -- a change from celestial rulers (and their priests) to human rulership. I would not make this suggestion if it were not for the fact that with the withdrawal of Mars and Mercury from the neighborhood of Earth, there was a worldwide change in conditions. Nothing would keep up the temple economies, when they were no longer needed to placate or plead with the destructive Gods, except the insistence of an autocratic leadership. If this can be accepted -- that at this time we see the first kingships -- then all other explanations, which place causes closer to us in time, can be dispensed with.

The period after 2300 BC saw the predecessors of the Olmecs establishing sites in the tropical region along the Pacific coast of Guatemala, some of which are today dated to about 2000 BC. In 1450 BC the first site on the Caribbean coast in Veracruz, Mexico, was established, San Lorenzo. It seems strange that complaints about leaders would be part of a history of the Gods except that this is also a history of the world. By the time of San Lorenzo, when we see what absolutely stupendous constructions the "greed for power" can accomplish, "leaders" had been well established for a thousand years.

Based on the complaints about leaders, as suggested above, I think we are in the period after about 2700 BC here (and for San Lorenzo, after 1440 BC). Here follows the third listing of trees. The remainder of this section deals with rulers, in association with the color of the trees at the cardinal points. It is a very generic presentation, unlike the exaltation of the leaders of Egypt, who built the Giza pyramids.

"Then the red foundation was established; the white foundation of the ruler was established; the black foundation was established; the yellow foundation was established."

"Then the Red Ruler was set up, he who was raised upon the mat, raised upon the throne."

"The White Ruler was set up, he who was raised upon the mat, raised upon the throne."

"The Black Ruler was set up, he who was raised upon the mat, raised upon the throne."

"The Yellow Ruler was set up, he who was raised upon the mat, raised upon the throne."

This is followed by more complaints about these rulers, and their limitations. It is interesting that the geographical concerns (the colors of the cardinal directions) seem to have shifted to actual persons or sites at this time. [\[note 21\]](#)

"As a god, it is said; whether or not gods, their bread is lacking, their water is lacking. There was only a portion (of what was needed) for them to eat together (...) but there was nowhere from which the quantity needed for existence could come."

"Compulsion and force were the tidings, when he [Jupiter] was seated (in authority); compulsion was the tidings, compulsion by misery; it came during his reign, when he arrived to sit upon the mat. (...)"

NOTE: "(...)" above represents lacunas in the original text.

There are similar sentiments about rulers expressed in a later section. I should point out that later text will claim the rulership of Saturn extended over the era before 3147 BC (after 6347 BC), and the rulership of Jupiter extended from after 3147 BC to the time of the arrival of the Spanish. Thus Jupiter's rulership extends over all of the "third creation."

The above text, and the ones following below, will seem confusing if the actual sequence of events in the era of 2500 BC to 2200 BC is lost sight of. To orient the reader, let me list a summary of events of the "Fall of the Absu" -- what is otherwise known as the "flood of Noah." The details of these were developed from more extensive sources from the Eastern Mediterranean region, India, and China, and presented in previous chapters.

- Near the beginning of the third dynasty in Egypt, Jupiter exits from the main portion of the Asteroid Belt, and again assumes a gigantic lower plasma outpouring -- the mountain. Pharaohs of this dynasty, which built the pyramids at Giza start to add "Re" to their names. This happened in a Katun 9-Ahau, ending about 2500 BC.
- This event of Jupiter again showing as an enormous globe on a mountain is taken in the *Chilam Balam* as the "reign of the third period." This event is taken as an anchor in this book of the *Chilam Balam* to list other events related to the later events of 2349 BC. The reason why the Olmecs or other people of antiquity selected Katun 9-Ahau will be detailed further below.
- I should note that a separate page of the *Chilam Balam* actually recounts all the events

of 2349 BC in the proper order. This will be detailed in the next chapter.

- At some time before 2349 BC the coma and tail of Jupiter disappeared again. From the fact that no additional "sun-temples" were built in Egypt after 2445 BC, we can suggest that Jupiter since that time had neither upper plumes nor a lower mountain of plasma. Jupiter was dead. My diagrammatic analysis of the travels of Jupiter away from the Sun, shown in the chapter 20, places this at 2438 BC, about 100 years before the "flood of Noah" in 2349 BC.
- In 2349 BC a transit of the Sun by Venus caused an Earth shock, tilting up the equatorial, which was hit by a plasmoid from Venus some hours later, identified in the Middle East as a gigantic dragon that waded in the blood of humans seen in the ocean of the sky for days. The initial plasmoid was followed by some nine additional, lesser plasmoid lightning bolts.
- The Absu turned red, and lightning fired across the rings. The equatorial rings disappeared soon after, and the southern stars first showed. Most prominent was the appearance of the Pleiades, high in the sky in the south at midnight.
- On the third night Jupiter had regained its coma, upper plumes, and lower mountain form. Jupiter was back from the dead.
- When the Absu collapsed, the Pleiades appeared for the first time -- an event which continued to be used in the future as a signal for celebrations of the "Day of the Dead" worldwide. At the same time the roof beams of the sky -- the intersection of the equatorial and the ecliptic -- showed up as a yellow road (the ecliptic) and a blood-red road (a remnant ring below the equatorial).
- The Moon showed up near Earth soon after. This was listed in the text above. But with the appearance of the Moon, the *Chilam Balam* notes that Jupiter was "not crying" at that time. The appearance of the Moon, or, more likely, its settling into a regular orbit, is assigned to Katun 7-Ahau, and this might in fact be so.
- One additional event, although it happened 200 years later, is noted in this collection of associated events: the giant coma of Jupiter blazed as if on fire and then disappeared to have Jupiter assume the look of a star. This is described below as "The Burning Tower," and it can (most likely) be placed in a Katun 8-Ahau.

The Burning Tower

As I warned, the events of the 24th and 22nd century BC are presented completely out of order. Thus we start with an event of the 22nd century, the burning of Jupiter. In what is assumed to be Katun 7-Ahau, although not altogether clear from the previous text, we have this strange incident described:

"Suddenly on high fire flamed up. The face of the sun was snatched away, taken from earth."

"This was his garment in his reign. This was the reason for mourning his power, at that time there was too much vigor. At that time there was the riddle for the rulers."

This duplicates the "Tower of Babel" story from the bible and supposedly other similar tales worldwide. We are between the year 2200 BC and 2000 BC. Since it follows the description of the rulership of Jupiter, it suggests the sudden demise of Jupiter, especially when we consider the phrase, *"The face of the sun was snatched away, taken from earth."* The Sun's face, after all, has not been taken away from Earth. This could only be a reference to Jupiter, who was still called "the Midnight Sun" by the Maya even in Classical times, and "Lord Sun."

In other text I have suggested that the Chinese dates for Yao's demise should probably be moved 100 years into the future, thus to 2150 BC. This would also be the death of Abraham. The year is fairly certain. Katun 8-Ahau (2.10.0.0.0), corrected to span 2167 BC to 2147 BC, would match this date. This date is also supported by other sources, as I have noted earlier.

The Planted Timbers

The following text follows on the "burning tower" without notification of a change in Katun. I think, however, considering what we know of the fall of the Absu in 2349 BC, and the events which accompanied this, that the sequence is completely incorrect. The planted timber and the crossroads mentioned below, follow directly on the removal of the Absu (the "flood of Noah") in 2349 BC, and have nothing to do with the later blazing of Jupiter. The coincident events are:

- The collapse of the "House of Nine Bushes" and the "baptism from the center of the sky" -- listed further below
- The appearance of the Pleiades -- listed directly below.
- The appearance of the ecliptic and the equatorial in the south skies (the cross roads or roof beams).
- The appearance of the Moon (but could be later) -- listed above.
- The north and south polar plumes -- the "timbers" below,
- The return of Jupiter -- already listed above.

This is Katun 2-Ahau, which ends nominally in 2325 BC (2.0.0.0.0), but the dates should be corrected to be from 2367 BC to 2347 BC. This thus includes the date from the Eastern Mediterranean of 2349 BC for the fall of the Absu and the "flood of Noah." By coincidence this Katun falls at the end of a Baktun.

"The planted timber was set up. Perishable things are assembled at that time. The timber of the grave-digger is set up at the crossroads, at the four resting places. Sad is the general havoc, at that time the butterflies swarmed."

Roys reads this paragraph as a local event, suggesting that rulers were assembled and executed at the intersection of two roads in the land of the Maya. I doubt if it has this specificity, for the few other political events which are recalled in other books of the *Chilam*

Balam list the names of the actors, in one instance from 700 years earlier. If this execution of chiefs had happened within the last 1000 years, we would have been told the names of the assailants and victims. The language of the Maya (and other people of the region) demands identification of an action in terms of the agents.

The "assembly of perishable things" are the Pleiades. Even in postclassical times the Maya held that the Pleiades were a sprinkling of seed maize. Certainly "precious things" is appropriate, because maize was held the highest status in all the Classical Maya culture. Since 2349 BC the Pleiades were seen above the intersection of the ecliptic and the equatorial, that is, at the location of the equinox, at the start of the constellation Taurus, as I have pointed out in other texts. As I have also pointed out previously, both the ecliptic and the equatorial were outlined as bright bands even still 1500 years ago, with the band of the ecliptic lasting into the 19th century. [\[note 22\]](#)

The equatorial showed at night as a band of glowing matter because of the debris still circling the Earth far above the equator -- left over from previous ages. After the Absu collapsed and most of the material dispersed away from Earth (and continued to fall to Earth until AD 1700), a single band remained, blood-red in color. The red ring is identified as the celestial snake Apep or Apophis in the Eastern Mediterranean region.

The remnant ring would probably show as spikes rising up into the sky at the east and west cardinal points. These regions, being beyond the edges of the Earth, would be lighted by the Sun (but with the west band being in shadow). These might have been the two "trees" of the east and west cardinal points, although I am more comfortable with assigning the trees to the lower Van Allen belt.

Near the time of the equinox the shadow of Earth would fall on the equatorial band but not on the band of the ecliptic (which is much too far away). Thus it looked like the red equatorial band crossed behind the ecliptic, although in actuality it was just the reverse. These crossed bands, with one band falling behind the other (a graphical representation known as the "Saint Andrew's Cross"), were used by the Olmecs and Maya as graphical indicators of the ecliptic throughout remote antiquity and through the Classical Era.

The ecliptic showed as a band of reflecting material which did not fade away until about AD 1840. This is the "Yellow Road" of the Chinese. The two bands intersected at Taurus, below the Pleiades, or probably near the end of Aries, since the red ring was below the equatorial. Mention of the assembly of "precious things" occurs directly before the mention of the timbers at the crossroads. In Southern Mexico and the Yucatan these two bands were displaced only some 20 degrees from being directly overhead where they crossed. In the *Popol Vuh* they are the roof beams of the house of the grandmother of Hunahpu and Xbalanque. They are also the river of pus and the river of blood which have to be crossed to get to the underworld. In remote antiquity the red band appeared only after the Absu had fallen. Because the planets traveled in one of the bands, they were called the crossroads.

Two timbers are mentioned. The "planted timber" is most likely the north polar plasma plume, the other, the "beam of the gravedigger" is the south polar plume, located at the crossroads (and close to the intersection). At a much later time (AD 400 to AD 700) the Milky Way was substituted, which became a primary symbol of creation and access to the underworld for the Classical Maya (as well as archaeologists). The Milky Way had not been seen in the south skies before the fall of the Absu.

The word "gravedigger," Roys notes, can also be translated as "hidiers" -- "anyone who buries or hides things." I have no idea what the Maya had in mind in attributing the new view of the bands of the sky (or the south polar beam) to the action of "hidiers," but, typical of Mesoamerican grammatical constructions, anything that appears has to be attributed, via an action-oriented verb, to some being. Perhaps the complete Absu and the moving waves of the rings were meant as the "hidiers."

From the *Popol Vuh* we have the interesting tale of the Giant called "Mountain" who digs a hole for the Four Hundred Boys and is nearly impaled by the timber which was to be the center post of the house. This timber was set up at the crossroads, under the crossbeams of the sky but also under the crossbeams of the house of the Four Hundred Boys.

The swarming butterflies probably visually represent the dispersal of the Absu or the lightning between the atmosphere and the rings of the Absu. A little later the "flood" will be mentioned.

Despite his demise, Jupiter certainly remained as the chief celestial deity. Of course his status as the ruler of creation would be reinforced by the returning plasma, called a "flower" later in the text, and the plasma bolt delivered in 685 BC. He will appear in Classical times as "God GIII" of the Palenque triad, and be called "Lord Sun."

Katun 3-Ahau: the Sun

The following describes the eruption of Venus in 685 BC. It is also listed out of place, because the event of 685 BC follows the repeated close calls by Mars and Mercury in the 8th and 7th century BC, which are described (out of place) further below. The Katuns are here named, but the individual pages are again being read in the wrong order.

"Then there came great misery, when it came about that the sun in Katun 3-Ahau was moved from its place for three months."

First, as I have noted earlier, the period of three 20-day months (60 days) exceeds the best estimate (from Zoroastrian sources) of the duration of the eruption of Venus by a month. Since the movement of the Sun was most likely charted to sunset locations along the horizon, I think the "sixty days" deal with the horizon setting location of the Sun.

The time interval here is one of three instances in this Book of the *Chilam Balam* where the period is given as an inclusive count. I first realized this for another instance, which caused me to look again at the other two. The three months are thus an interval of two "Uinal" months of 20 days, a total of 40 days. Having independently determined the ending date of the blazing of Venus and Mercury as July 25th, and a starting date as a new Moon before that, it was satisfying to realize that the "three 20-day months" mentioned here represent the 40-day interval between two new moons at June 15 and July 25 (Gregorian calendar dates).

I think we can suggest the veracity of these data from the fact that in all three instances, by allowing for inclusive counting, the intervals can be matched against other known dates and made sense of. This also again verifies the fact that the Long Count existed only since 747 BC, for no such accurate dates or intervals exist before 747 BC. (The inscriptions at Palenque were retrocalculated.)

"After three years [three heaps of years] it will come back into place in Katun 3-Ahau. Then another Katun will be set (in its place)."

Roys notes that "three years" literally reads "three heaps of years" which could be a longer period than three "Tun years" (of 360 days), or it could mean a shorter period, but apparently not longer than the 17 or 18 years it would take to reach the end of Katun 3-Ahau. I think a "heap" is likely to be a group of five, but of the 260-day Tzolkin calendar years. (As explained by other contemporary commentators on the mathematics of the Maya, this would be a "bundle" -- a line representing a count of five dots in the numeric notation. Of course a group of 20 is also called a bundle, as is, in later Central Mexico, a group of 52 years.)

The 15 "years" (three heaps of five) is probably a measure on the Tzolkin calendar which rotated the same day-name and day-number combination into place at the same horizon sunset location for a zenithal passage of the Sun. I am assuming a zenithal passage because these were deemed to be very important to each ceremonial site.

In actuality the location along the horizon of the zenithal sunset remained the same after 685 BC as it had been before 685 BC, to within a fraction of a degree, but the calendar day (our calendar) would move back by 10 to 17 days, as follows, depending on the latitude.

location	latitude	zenithal passage of the Sun		difference in days
		before 685 BC,	after 685 BC	
Izapa	14.960	August 21	August 11	10
Monte Alban	17.033	August 16	August 4	12
La Venta	18.125	August 14	July 31	14
Teotihuacan	19.638	August 10	July 25	16

The Tzolkin calendar, not being an annual calendar, would rotate a different day-name into place each following year. Normally, after 20 rotations of the Tzolkin, the same day-name would appear again on the same day of the Gregorian calendar (without accounting for the

slippage due to leap days).

As so tersely expressed by the *Chilam Balam*, it would take three times five rotations of the Tzolkin ("bundles of years"), not the normal twenty, for the Sun to again return to the same day-name and day-number combination. We can find this easily, for we do not need to access the Long Count calendar, and we do not need to know the starting date or ending date. But we will have to "discount" the author's quirky inclusive accounting. "Fifteen years until" will mean a difference of "fourteen years." This is the second instance of an interval expressed as an inclusive count. It is then a simple matter to subtract 14 multiples of the 260-day Tzolkin from multiples of the 365.25-day year, until a difference is found which matches the differences in calendar days in the chart above.

In fact, 14 Tzolkin rounds are 12.5 days short of ten 365.25-day years. $14 * 260 - 10 * 365.24 = - 12.40$ days. This is the change in days experienced at Monte Alban. Monte Alban may thus be the source of the lowland Yucatan Maya author's original books. Already 600 years old (since the collapse of the Maya kingdoms) at the time they were read in the 16th century AD, the original source dates back well over 2000 years to 685 BC.

The first date of a zenithal passage of the Sun at Monte Alban, before 685 BC, would have been August 16, 686 BC, 6.3.3.6.11 7-Chuen. Fourteen times 260 days is 0.0.10.2.0 Long Count days. Adding, this gives 6.3.13.8.11 7-Chuen. This falls on August 3rd, 676 BC. One more day needs to be advanced to complete the count, thus August 4. Either way, the difference is 12 or 13 days. (This calculation is unaffected by the change in the calendar instituted at a later date by Monte Alban, in 607 BC. See the chapter "The Day of Kan.")

The same addition of 14 Tzolkin periods to the pre-685 BC dates results in (subtracting 12.5 days as 13 days):

- Izapa: August 9, not 11;
- La Venta: August 1, not July 31;
- Teotihuacan: July 22, not 25.

La Venta is close, however, and might stand as an alternate source for the original glyphic books from which Book 10 of the *Chilam Balam* was eventually composed. La Venta is somewhat north in latitude from Monte Alban.

I should also follow up on my earlier note on the *Chilam Balam* that the return of the Sun was accomplished before the end of the Katun, "it will come back into place in Katun 3-Ahau." As outlined above, the displacement on the Tzolkin calendar would have amounted to less than ten (current) years. The year 685 BC less ten years is 675 BC. This Katun 3-Ahau starts in 689 BC and ends in 669 BC, bracketing both the nova event of Venus in 685 BC and the date of the return of the Sun.

Only a short paragraph is recorded for all of Katun 3-Ahau, although the writer will

repeatedly return to the event of Katun 3-Ahau. This was one of the most monumental events in prehistory. It changed the religions and probably the enterprises of Mesoamerica and started people on a path of independent thinking, as elsewhere in the world.

The writer continues with laments, presumably related to Katun 3-Ahau:

"The 'ramon' fruit is their bread, the 'ramon' fruit is their drink; the 'jícama cimarrona' is their bread, the 'jícama cimarrona' is their drink; what they eat and what they drink."

"The 'ix-batun,' the 'chimchim-chay,' are what they eat."

The foods listed are those eaten at a time of famine. Roys notes, however, "Most of the preceding paragraph concerning Katun 3-Ahau appears to be an interpolation. It is not found in the Tizimin and Mani versions," and notes that two other versions of the *Chilam Balam* list the misfortunes ("for each of the twenty years") of Katun 5-Ahau instead.

This is followed by a most curious sentence:

"These things were present here when misery settled, father, in Tun 9."

The Katun 3-Ahau text missing from other copies of the *Chilam Balam* may reflect the care the Maya took in hiding all notice of Kukulcan (Quetzalcoatl) from the Spanish priests. Is the meaning of "father" from a statement about of the exact genesis of Kukulcan, addressed to a Spanish priest?

It might very well be that this interpolation is a confession to a Spanish priest. But it is couched in talk of miseries, rather than the significance of Kukulcan's death and resurrection. Which may be why "the miseries" as well as the reference to "Tun 9" and to "father" is missing in other *Chilam* texts.

If correct as posed by me, then we have here the most valuable aspect of this document, a clear statement about the year of the Kukulcan event -- the earthly appearance of Quetzalcoatl and his death.

"Tun 9" is the ninth year of Katun 3-Ahau. Then "these things" would have happened in 680 BC. My first reaction was that the scribe had the Tun date wrong. If the event happened in 685 BC, then it should have been Tun-4 of Katun-3 (6.3.4.5.15). If the event happened in 680 BC, however, then it would have been Tun-9 (6.3.9.5.15) instead.

Then I remembered that my selection of 685 BC was based on correcting the established error in Eastern Mediterranean chronology. It actually was the year 680 BC on the Julian calendar, the very calendar that the Spanish priests had introduced into the Yucatan. The scribe thus did not make a mistake, but properly identified the year. At least, that is what it looks like to me: he identified the year in the calendar of the invaders when the Sun "did not

follow its course for three months." In fact, he managed to retrocalculate the Julian calendar into an era before the Julian calendar was established.

The importance of this short paragraph about the Sun can be gauged from the inclusion of three specific date values: it lasted "three months," the Sun "returned" in 14 Tzolkin periods, and it happened -- ended -- in year (Tun) nine of Katun 3-Ahau -- 680 BC on the actual retrocalculated Julian calendar of the invaders.

Two more data points will be added further below: the date of the release of the plasmoid by Jupiter will be identified and the interval between the last close sighting of Mars and the day the plasmoid arrived will be given.

At this point the list of Katuns is interrupted. To this point the phantom Katuns have progressed in the correct order, that is, Katun 11-Ahau, Katun 9-Ahau, Katun 7-Ahau, Katun 5-Ahau (though I have some problems locating Katun 5-Ahau), and Katun 3-Ahau. Katun 11-Ahau was used at the beginning simply from the notion that all history starts in Katun 11-Ahau. But Katun 3-Ahau can certainly be assigned to a definite time in the past which matches what we know from other sources.

The next Katun should have been Katun 1-Ahau, but now the writer introduces Katun 13-Ahau, with a single line about foreigners.

After introducing Katun 13-Ahau, the *Chilam Balam* then continues with a radically different listing of events. Events are now listed by Katuns in order, in the manner of the "prophecies" of the other Books of the *Chilam Balam*. This has all the look of an additional record from another original source. Near the end, when the writer restarts in Katun 11-Ahau, yet another primary source seems to have been accessed.

"At that time there were the foreigners. The charge (of misery) was sought for all the years of (Katun) 13-Ahau."

It is possible that the mention of Katun 13-Ahau is a very early transcription error (reading 13 for 3), or this may be a reflection of the expected content similar to other Books of the *Chilam Balam*, where Katun 13-Ahau is indeed associated with prophecies of foreigners, the Spanish. In another Book the foreigners arrive in Katun 5-Ahau and are Caribs. Other copies of the *Chilam Balam* have nothing on Katun 3-Ahau, and list "miseries," year by year for Katun 5-Ahau, which is missing from this copy of the *Chilam Balam* -- which is the version from Chumayel.

The 8th Century BC

The approaches by Mars in the 8th century BC (and the 7th century), which devastated Persia, Anatolia, Greece, and Italy, at 35 to 40 degrees latitude, did the same damage in Central America, as indicated by the fact that the number of villages in Mesoamerica decreased markedly in the 8th century BC.

But the *Chilam Balam* at this point is given over to descriptions of flowers, colors, and fragrances -- arcane celestial details never noticed (or mentioned) in the Middle East. Perhaps we are now seeing the transcription from another source, "The Book of Flowers." Mars is only mentioned twice.

From dates extracted from the records of the Middle East the destructive events of the 8th and 7th century should be spread over four Katuns, from 747 BC to about 687 BC -- if we start in 747 BC. This would be the time span of Katun 11-Ahau (767 BC to February of 747 BC), Katun 9-Ahau, Katun 7-Ahau, and Katun 5-Ahau (ending in 687 BC). There is no reference to the last two, but the first two are listed and the events are described.

If, on the other hand, we start with what seems to be the full record, based on archaeological data of destructions in the Mediterranean, then we need to start in 806 BC. The record would have to include the additional Katun 4-Ahau (ending in 806 BC) through Katun 13-Ahau (ending in 768 BC). (Katun 4-Ahau, Katun 2-Ahau, and Katun 13-Ahau.) But there is no reference to these Katuns. Most likely this is because there were no Long Count records compiled before 747 BC. Checking back at later times, nothing was seen of the first four close passes of Mars, except as implicit in the name "Bolon Dzacab," "Nine Lives" -- for Mars did show up a total of nine times.

It is interesting that Mars is known as "Nine Lives" during the 8th and 7th century BC -- when he had also appeared close to Earth nine times before 3147 BC (as I surmised from Eastern Mediterranean sources). At first I thought that it was the nine appearances in the 8th and 7th century BC that became the basis for his name. But it seems to be a coincidence. His name was selected in remote antiquity, before 3147 BC, later known as "this first Bolon Dzacab." The giant greenstone mask-shaped floors at Olmec La Venta, apparently buried as a means of warding off or appeasing Mars, represent the face of a Jaguar in the form of the glyph for "nine." This name might thus have existed before it could have been determined how many times Mars would show up during these two centuries.

It is strange that the first four close passes of Mars between 806 BC and 747 BC were not recorded and, in fact, there were apparently no preventative ceremonial sculptures dedicated to Mars in the Olmec Veracruz region of Mexico during this period. Tres Zapotes, which had taken over primacy from San Lorenzo in about 850 BC, continued to carve "Venus heads" during the 100-year period before 747 BC, and thus only paid attention to the simultaneous

appearance of Venus and Mars in 776 BC.

But the close pass of Mars in 747 BC seems to have destroyed Tres Zapotes, and La Venta was established to celebrate (or ward off) the comings and goings of Mars. La Venta was aligned to a sunset over the mountain Popocatepetl for the day of the Earth shock of 747 BC, when the length of the year changed (but not the axial inclination) and the Olmec Long Count was instituted. The close pass of 747 BC, plus the next four (a total of five), were all remembered at La Venta.

The actual date for the alignment at La Venta is February 28th, but for an angle representing a sunset under the condition of an axial inclination of 30 degrees for the Earth. There are two additional alignments, representing a sunset on April 19th, to the mountains Citlaltepētāl and Volcan La Malinche, also selected for an axial inclination of 30 degrees. After 685 BC, when the axis of the Earth changed to an inclination of 23.5 degrees to the normal of the orbit, La Venta was reconstructed to have its long axis at right angles to a sunset on February 28 for the current axial inclination of 23.5 degrees. (Details in a later chapter.)

Thus the close pass of Mars in 747 BC was noted in the reconstruction of the ceremonial center at La Venta, and the visit is recorded in the *Chilam Balam*, appropriately in a Katun 11-Ahau -- the Katun which actually ended the previous era on February 28, 747 BC. A little later in the text the nine concurrent visits by Mercury are recorded as the descent -- with Bolon Dzacab -- of Bolon Mayel, Nine Fragrances. I'll detail Bolon Mayel further below.

"Then it was that the lord of (Katun) 11-Ahau spread his feet apart."

"Then it was that the word of Bolon Dzacab [Mars] descended to the tip of his tongue."

Bolon Dzacab ("Nine Lives") is Mars, to be distinguished from the Mars seen before 3147 BC, who is called "this first Bolon Dzacab," and also differing from Lahun Chaan ("Ten Sky") who appears to be Mars for 300 years after 3067 BC. The "tip of the tongue" is the bottom of the electric arc from Mars (or an extended cone of plasma perhaps in the form of dust). Mars, as God K or God G-II, is often depicted in Maya iconography with a single leg, acknowledged as representing lightning. (On the much later Aztec "Calendar Stone" he is presented in the center with his tongue hanging down.) "Spread his feet" refers to how a growing child is carried on the hip (after Luxton). It is thus a simile for "establish."

The text here is perhaps with reference to all of the period of 806 BC to 747 BC. But notice that, as elsewhere, nothing is said of the change in calendars which happened after 747 BC. (There is, however, a note about the introduction of a calendar at the time of the "third creation," listed on a separate page of the *Chilam Balam*.) Except for the complaints about the rulers who imposed themselves on the Olmecs or Maya, no civil events are ever touched upon in Book 10.

With respect to the phrase "tip of his tongue," there are some Olmec rock carvings from this

era of an iguana (or what looks like an iguana) with his tongue reaching up and touching the bottom of cloud glyphs. Cloud glyphs look like pancakes with down-curved edges. It would be appropriate of Mars appearing in the skies, reaching down to Earth with a sustained lightning bolt. Although the tongue here goes in the wrong direction.

But the following Katun 9-Ahau, from 747 BC to 727 BC (further below) includes a surplus of observations, mostly in terms of flowers. Fragrances are also mentioned, which we recognize from Velikovsky's collected anecdotes, although Velikovsky places these in 1492 BC during the interaction with Venus. [\[note 23\]](#)

The Day of Kan

Another event is inserted here, related, as the text states, to Katun 9-Ahau, but we are no longer in the 8th century BC. It is, in fact, in error. The event listed below, the fall of the Absu -- the flood of Noah -- happened in Katun 2-Ahau (2.0.0.0.0), corrected to end in 2347 BC. There is, of course, a Katun 9-Ahau before the "flood of Noah," 148 years too early, just as there is a Katun 9-Ahau after the "flood of Noah," 40 years too late.

I am inclined at this point to suggest an alteration of the original text which was made on purpose in antiquity. More on this below.

"Then the charge of the Katun was sought; nine was its charge when it descended from heaven. Kan was the day when its burden was bound to it."

"Then the water descended, it came from the heart of the sky for the baptism of the House of Nine Bushes."

Except for the fact that we are presented with a deluge, the rest does not make much sense at first.

Bolio translates these two lines as:

"Nine were their cargoes when he came from the sky. The day of Kan was the day when his cargo was tied up. It was when the water came from the sky for the second birth, from the house of the one of the 'innumerable years.'"

This relates the fact that we are in a Katun named 9-Ahau, as well as the fact that the event, the baptism, happened on the day of Kan. The author of the *Chilam Balam*, on the basis of his sources, has full confidence that the "day of Kan" should be associated with the "second baptism." I will address this first.

The "second birth" is a second flood. The flood is suggested by Bolio. The history we are dealing with ignores hurricanes and tsunamis, and has so far only listed one other flood, the event of 3147 BC. The flood mentioned here is the only other mention of a flood. Notice that

it "came from the center of the sky" and that it baptized (wet) the "House of Nine Bushes."

I think we are looking at the event which in other parts of the world is recognized as the "flood of Noah." The "House of Nine Bushes" is the Absu or Duat, the last described in Egypt (at 30 degrees latitude) as consisting of seven rings. In the Yucatan (at 20 degrees latitude) it was seen as consisting of nine rings -- or rows of bushes. The Maya or their predecessors saw an additional two rings closer to the Earth's equator.

In Egypt and Mesopotamia the seven rings of the Duat or Absu were understood to be an ocean in the south, but also as access to the "Underworld." In the Yucatan the 9 layers were also the underworld, the domain of "The Nine." But the Olmecs or Maya did not equate the rings to a sea, as far as I know. This may be because of the steep angle at which the rings stood in the sky, and the intimate contact of the land with real oceans.

[Image: 4-Ahau and 9-Ahau.]

This passage, like so many others, is not only displaced from its proper sequence, but also seems referenced to the wrong double-decade (Katun). The question thus remains, if most of the other events are properly slotted in Katuns of the correct names, why is this "flood" event -- plus the appearance of the Moon, the first showing of the Pleiades, the appearance of the rafters of the sky, and the polar plasma plumes -- all of which deal with the flood of Noah, late by 40 years? The "flood of Noah" can be placed with good certainty in 2349 BC from the efforts of many chronographers of the Mediterranean region (and matches good guesswork from China in 200 BC).

First, it could be suggested that the assignment of the "second baptism" to Katun 9-Ahau is a transcription error and that Katun 9-Ahau was misread from Katun 4-Ahau.

Errors in transcription, both at the time the *Chilam Balam* was written and at earlier times, are certain. Roys notes a number of them for the *Chilam Balam* text. J.E. Thompson has noted some dozen errors in the *Dresden Codex*, dating from about AD 1200. Vincent H. Malmstrom, in *Cycles of the Sun, Mysteries of the Moon* (1997), has noted a transcription error in Stele C from Tres Zapotes. The task of transcribing the codexes to new plaster-coated bark books by painting the glyphs, illustrations, and diagrams, must have represented a mind-numbing task which could easily result in subtle errors, like the addition of a bar to the glyph for 4-Ahau.

But there is a more elegant solution which comes forward to resolve the "Katun 9-Ahau" issue. The details, which I have promised a number of times in this text already, are as

follows:

The day-name "Kan" is the fourth day of any Katun. The first day of Kan in the Katun 9-Ahau after the "flood of Noah" is July 26, 2286 BC -- 2.2.0.0.4 2-Kan, on the "August 11" correlation (this will suggest that it was a very old alteration of the text). If the year is wrong, it is the only one in all of the *Chilam Balam* (making allowances for the scribe's insistence of placing all planetary events in Katun 9-Ahau). With both the Katun and the day listed, it would seem to pinpoint a very certain date. It could signify the completion of the fall of the Absu, but this would have been accomplished in a few days, not 40 years later.

However, July 26th was the celebration of New Year (as "the day of Kan") among the Maya when the Spanish invaded in the 16th century. Bishop Landa (in circa AD 1590) mentions that the new-year day of the Maya was on July 26 and always fell on the Tzolkin days Kan, Muluc, Ix, and Cauac -- in rotation. July 26 was celebrated as the new-year day, not only by the Yucatan Maya and regulated by the priests of the ceremonial center of Edzna, but also at Teotihuacan in Mexico, a thousand miles west from Edzna. Teotihuacan was established in circa 200 BC as an Olmec outpost. Of course it should be understood that this was not our calendar date of July 26th, but is the day when the Sun rose and set at a certain location along the horizon, which today equates to July 26th. For both Edzna and Teotihuacan this included the passage of the Sun directly overhead.

The resolution of why Katun 9-Ahau was understood to be the year of the end of the "third creation," rather than the correct year of Katun 4-Ahau, is buttressed by four concepts.

First, it was known that a calendar had been instituted at the time of the "second baptism" (as was true worldwide). Actually, I suspect that this was the addition of 13 numbered days to the established 20 day-names of the Tzolkin calendar.

Secondly, the start of the year was celebrated among the Maya, as at Teotihuacan in the Valley of Mexico, on July 26th. July 26th actually celebrated the day after the delivery at the Sun of the plasmoid from Jupiter in 685 BC. If this last was a "fourth creation" of the world, it might seem reasonable to the Maya that the previous creation of the world would also start on the same Tzolkin day-name.

Third, the Maya and the Olmecs seemed to have been convinced that the Tzolkin calendar determined celestial events. I'll explore this more in a following chapter. It was this thinking which led to an active search by the Maya (or more likely, the Olmecs) for the "day of Kan" among the records of the past -- a day of Kan which fell on the equivalent calendar date (sunset location) of July 26.

We must allow that the Maya were perfectly capable of calculating backwards to discover on what day in prehistory the setting Sun on July 26th coincided with the fourth day, named Kan, of a newly started Katun.

Of course, a day named Kan falls on July 26th every few years (at about 20-year intervals). However, the Long Count date of 2.2.0.0.4 2-Kan is **the only instance** in the whole Long Count calendar -- 5200 years -- that the **first day** of Kan falls on July 26.

"The day of Kan," July 26th, marked the end of the nova event of the Sun in 685 BC (the termination by the plasmoid of Jupiter) as it was celebrated a few hundred years later. Even though July 26 did not fall on a day of Kan in 685 BC, it became celebrated as the "new year day" among the Maya, having inherited this significant date from the teachings of Olmec Teotihuacan. Much later, before perhaps 300 BC, scribes assigned this "important date" to the event of the "second baptism." The Katun during which July 26 fell on the first day of Kan, was researched and found to have occurred only once in five thousand years since the start of the current era -- in the second Katun of the second Baktun (2.2.0.0.4). [\[note 24\]](#)

Last, as was known among the Maya, all important celestial events happened in Katun-9 periods. The first day of Kan, July 26th, also occurred in a Katun-9.

This has to be the solution to this apparent error in chronology. We are looking at a correction to the historical records, made in antiquity, which seemed eminently reasonable at the time. There is no way that we can manipulate Katuns and Baktuns to account for the difference of 40 years and find the "day of Kan" elsewhere in the past. We could attempt to add together surplus days to the solar year for the periods between 747 BC, 1492 BC, 2193 BC, and 2349 BC, but these will not add up to 40 years. [\[note 25\]](#)

If the Olmecs in antiquity investigated the "day of Kan" for the end of the "third creation," they must have had something to go on besides the notion that the recreation of the world would (or should) have happened when the first day of Kan of a Katun fell on July 26th. I would suggest that, because Jupiter had shown up in a full display three days after September 8th, 2349 BC, this would be "day three" of a Tzolkin calendar round which started with the plasmoid from Venus. The next day is the "day of Kan" -- always the fourth day of a new Katun, and New Year's day for the "third creation."

The error in assignment in the *Chilam Balam* stems from the fact that the day of the "third creation" simply could not be retrocalculated 1600 years later when the Long Count was adopted, and certainly not another 800 years later, when the Maya attempted it (using a 365.24-day year), for the length of the year had changed three times since 2349 BC.

The Maya knew the Tzolkin calendar governed the Gods responsible for creation, and so the new Katun would be a Katun 9-Ahau. This was logical since it was well known from 747 BC that all of pre-history could be assigned to the previous Katun 11-Ahau. Katun 9-Ahau follows directly on Katun 11-Ahau.

It is also possible that a Katun 9-Ahau had actually started at the time of the "third creation" in 2349 BC. In which case the fourth day would be a day of Kan. This is the day after Jupiter returned from the dead. What a separate page of the *Chilam Balam* says, as part of a list of

events associated with the fall of the Absu (the flood of Noah), is:

"And then days of the year were introduced."

Let's assume from this that the 260-day Tzolkin was introduced on September 6, 2349 BC, using a rotation of 13 days to follow the waxing and waning of the Moon (even though the Moon may not have shown up exactly that soon). It is difficult to imagine how soon this calendar was devised. But once established, it would have been obvious that the fourth day of the new calendar, which would have been a New Year's Day, was a day of Kan. This would celebrate the end of the "third creation."

Since Baktuns and Katuns had certainly been tallied since 3147 BC, it is very possible that this day of Kan -- September 9, 2349 BC -- was indeed the fourth day of a Katun named 9-Ahau. That also means that, as had happened in 3147 BC, the previous Katun would have been named 11-Ahau -- the Katun which always represents all of prehistory. This coincidence of ending an era with a Katun 11-Ahau would happen again in 747 BC. And a day of Kan shows up on a retrocalculation for April 19, 1493 BC (Exodus, my date of 1492 BC).

Thus if a "day of Kan," which coincided with an equivalent calendar date of July 26th, was found as the fourth day of a Katun 9-Ahau, then the Olmecs would have been justified in suggesting that during this particular double decade the world had been recreated. Even though 40 years late, only Katun 9-Ahau of the second Baktun (2.2.0.0.4) qualified in the complete record of the 5200 years of the cycle of 13 Baktuns.

Now to a previous sentence, which seems out of place. This is a sentence which may need to be separated from the line about "the baptism of the House of Nine Bushes":

"Kan was the day when its burden was bound to it."

The day of Kan here is most likely 6.3.4.5.4 17-Chen 2-Kan which is July 14, Gregorian, 685 BC (July 21, Julian). It is the day, I suspect, that the plasma bolt left Jupiter in 685 BC. The "burden" which "was bound to it" is the plasmoid from Jupiter. The day of binding was the start of the travel from Jupiter. "It" is the day named Kan, not any other entity.

The "day of Kan" had been known to be the day that creation ended in remote times, both in 2349 BC (although assigned to the wrong Katun) and in 1492 BC (of which the time-keepers were more certain). A change to the August 13 Tzolkin calendar had found that the equivalent calendar date of the latest change, July 14, 685 BC, also happened on "the day of Kan."

This note about the "day of Kan" when "the burden was bound to it" -- bound like a pack carried by a trader -- is the fourth chronological reference to the events of the year 685 BC. This date only becomes important later, when we learn that it signifies the decision of Jupiter not to have Mars destroy creation.

The calendar dates mentioned above become clear on an inspection of alignments with horizon location for Olmec coastal and Valley of Mexico ceremonial sites (for which see a following chapter). Alignments were made, at different sites, for April 19th (representing the Earth shock of 1492 BC), February 28th (the shock of 747 BC), and July 9th, 21st, and 25th (all dealing with Jupiter in 685 BC). The start of the blazing of Venus and Mercury in 685 BC, 40 days before July 25th, was not celebrated. The Maya, and, in fact, all of Mesoamerica, only celebrated completions, not the start of events.

The Flowers

The next few lines first attribute the deluge (of 2349 BC) to Mars. The reading seems to present a simultaneous close passage of Mars, as Bolio's translation, above, suggests. (This may reflect the events after 1936 BC, the destruction of Sodom and Gomorrah, which followed on 2349 BC.) Any passage of Mars would have brought torrential rain storms and hurricanes to the region, in addition to destruction. The lines following this do not return to the topic of Mars, but introduce a new player, Mercury.

"With it descended Bolon Mayel [Nine Fragrances]; sweet was his mouth and the tip of his tongue. Sweet were his brains."

I suspect that the insertion further above is meant to relate the "water from the sky" (at the time of "Noah's flood") to Mars in the 8th century BC (or Mercury, as here), even though no mention is made of rains or hurricanes associated with Mars. I have a note further below on the sudden topical grouping of events by the author.

"Sweet was his mouth, etc.," -- Meaning either that this celestial agent was not a threat to humans, or the sweet mouth is associated with the "fragrances."

"Bolon" -- nine -- suggests nine appearances of Mercury. Mercury might have been seen close to Earth nine times. But I think that this started in 806 BC. As I have suggested earlier, the orbit of Mercury was elongated since 3147 BC, extending past the orbit of Earth, -- equivalent to what Mars was doing. It was likely in sync with Mars, possibly showing up near Earth when Mars did so. The two planets were known throughout the world as "the twins." The Earth shock by Mercury in 686 BC follows directly on an appearance of Mars, as substantiated by a note on the timing of this further below in the *Chilam Balam*. "With it descended.." affirms that Mars also showed up 9 times.

More on Mercury after another interruption. At this point the text returns to Mars, or the satellites of Mars, rather than Mercury, except that the "honey of the flowers" would have to refer to Mercury.

"Then descended the four mighty supernatural jars [or, two mighty demon bats], this was the honey of the flowers."

Roys's footnote reads:

"For this sentence the following is substituted in the Mani and Tizimin versions of this narrative: 'Then descended two mighty demon bats who sucked the honey of the flowers.'"

That might make sense in representing the two satellites of Mars, which are elsewhere in the world described (during this period) as raging spirits, scorpions, snakes, and chariot wheels. Mars, lacking a magnetic field, would have had a closely held plasmasphere (coma), which might very well have consisted entirely of ionized dust (as is seen today). Once Mars entered Earth's plasmasphere the coma of Mars would have expanded to meet the Earth's electric field, rather than being subjected only to the Sun's much lower electric field outside of Earth's plasmasphere. The two satellites of Mars would have continuously distorted the coma of Mars. Seen on the day side of Earth, this might have presented itself as a flapping dark shape. (The satellites of Mars would be seen east and west of the globe of Mars because Mars passed Earth laterally.)

As I have noted before, according to the modeling by Patten and Windsor, Mars would alternately appear near Earth in going toward the day side of Earth and going toward the night side of Earth. That might account for the appearance of "two" mighty demon bats, rather than 4 or 5 (between 747 BC and 687 BC). Thus two times out of the five recorded appearances of Mars.

This would have happened in the fall of the year, and likely represented a passage of Mars on the day side. The spectacle in the skies, back-lighted by the Sun, would have been astoundingly different from the view of a passage of Mars at night. We may have to assume that the Mani and Tizimin versions of the *Chilam Balam* corrected the information presented in the books of Chumayel.

The "four mighty supernatural jars," on the other hand, might also describe Mercury. After four appearances with Mars (and likely close by), the fifth appearance of Mercury was distinctly different, for it was jolted by Earth (686 BC), and disappeared to a new orbit close to the Sun. Nothing is made of the "burning tower" apparition, however, the sight of which might have only been experienced much further north.

Thus, after having mentioned the appearance of Bolon Dzacab, Mars, in 747 BC, the *Chilam Balam* now has reference to the four additional appearances of Mars -- as "mighty demon bats" or "supernatural jars" rather than as Bolon Dzacab. This coincides with the four giant heads found at La Venta, which were buried in a line north of the pyramid.

Since the "mighty demon bats" suck the honey of the flowers (mentioned above), it suggests the near simultaneous appearance of Mars and Mercury in the skies. The Olmec Jaguar sculptures at La Venta, and later, add the snout and fangs of a snub-nosed bat to the jaguar face. [\[note 26\]](#)

Of course I have here selectively taken the number of appearances from one source (four jars) and the description from another (two bats). But I think the number "four" is completely justified from the number of heads found at La Venta, and the "bat" description is justified from the sculptures of bat-faced jaguars at La Venta.

In the next few lines of the text, all about flowers, clearly refers to Mercury, which has a minor magnetic field, and would thus support tri-lobed plasma forms at its poles -- looking like flowers. Mars, without a magnetic field, would not.

"Then there grew up for it the red unfolded calyx, the white unfolded calyx, the black unfolded calyx and the yellow unfolded calyx, those which were half a palm (broad) and those which were a whole palm (in breadth)."

The four colored "calyxes" again look like a distribution to the four compass directions. The half palm and full palm widths describe the lower and upper tri-lobed plasma cones above and below the magnetic poles of Mercury. I should point out that Mercury and Mars were seen in a side view from Earth, since the rotational axis of both planets would nearly parallel that of the Earth. Thus the flowers of Mercury would have extended in a north and south direction.

The flower forms, by the way, are understood in Egypt and the eastern Mediterranean region as wings. From this we have the "winged disk" iconography, which is clearly associated with Mercury.

The north magnetic pole would have a much larger size ("a whole palm") flower form. If these represented the polar plasma forms of a planet, the planet need not have come that close to Earth, since Mercury's coma might easily have been twenty times the diameter of the planet itself, with the polar plumes much larger. Yet, what a threatening image this would have presented! It is a palm held at arm's length. The "whole palm" representing the size of the flower shape at the top, and the "half palm" representing the width of the flower shape at the bottom. A "palm" in width is about 5 degrees of the sky -- ten times the diameter of the Moon.

"Then there sprang up the [1] five-leafed flower, [2] the five drooping (petals), [3] the cacao (with grains like) a row of teeth, [4] the 'ix-chabil-tok,' [5] the little flower, [6] 'Ix Macuil Xuchit,' [7] the flower with the brightly colored tip, [8] the 'laurel' flower, and [9] the limping flower."

On a whim I decided to count the specific flower species, as listed above, to see if this would account for the name Bolon Mayel, "Nine Fragrances."

Bolio has:

And at the same time blossomed [1] the flower that is watered and [2] the one that has

holes; and [3] the wavy flower of cocoa and [4] the one never sucked on [this is Ix Macuil Xuchit, "Five Flower," the Mexican god of music and dance], and [5] the flower of the spirit of color, and [6] the one that always is a flower, and [7] one with a crooked stem."

With Bolio's rendition we are two flower species short of a count of nine, and obviously there is a pun inserted in the middle of the list. It is interesting that these flower forms could be counted over a period of 120 years from 806 BC, if, as I have assumed, Mercury accompanied Mars in these instances, even though the record of Mars is only shown for the instances after 747 BC. The last appearance of Mercury, in 686 BC, was aborted, of course.

"After these flowers sprang up, there were the vendors of fragrant odors, there was the mother of the flowers."

Fisher adds the following to Bolio's translation,

"These flowers that came out were the 'Comayeles' [Ah Con Mayeles, "the offerers of perfume"], the mother of flowers."

Roys notes,

"In the Tizimin and Mani versions we find: 'there was the house of the flowers.'"

... meaning that it (or something) was seen as a celestial apparition.

This is followed by yet additional complaints about rulers. But first let me point out again that both the "flowers" and the "fragrances" could only refer to a planet with a magnetic field and with an atmosphere. This could not be Mars. In fact, I will also suggest that the "house of flowers," mentioned above, is Jupiter, to which the text will get to soon. On about June 9th Jupiter developed a coma and became a "house of flowers." "House of flowers" is the Mesoamerican name for a pyramid, actually, "flower mountain." The lightning bolt to the Sun did not leave Jupiter until July 14th.

"Then there sprang up the bouquet of the priest, the bouquet of the ruler, the bouquet of the captain;"

"... this was what the flower-king bore when he descended and nothing else, so they say. It was not bread that he bore."

"So they say," is a reflection on earthly rulers. Bolio has:

"When the latter [the flower God, Mercury] came down he had no equal. 'Look at him,' they said, 'he does not spill his cargo.'"

... which has a somewhat different sense. It suggests that the flower shapes were not dropped

to Earth, or (more likely) that no electric contact was made with Earth. How Bolio arrived at this reading, which seems correct, is inexplicable. It would seem to suggest that the close overhead passages of Mercury were harmless to Central America -- in clear distinction to the destructiveness of Mars. Mercury may not have come very close, like Mars, but remained at a considerable distance. The last contact with Mercury, at any rate, was felt in North America in Alabama. (As developed in an earlier chapter.) From this, too, we would get the sense that the text has shifted entirely to a description of Mercury, and perhaps the reference to the satellites of Mars, above, is in error.

The sense to me is that the lines about the rulers are an editorial comment on the crop surpluses required by the ruling elite and the luxury goods being extracted from the citizens by the Maya ceremonial centers and through the long-distance trade which flourished since about 1500 BC. Unlike Egypt, and especially Mesopotamia, where feathers, metals, and precious stones were collected for the benefit of the gods of the temples, these goods (plus the food staples required to sustain both the trade functions and the leadership) were for the personal consumption and adornment of the rulers. This is similar to the situation in China. The rulers, in their shamanistic functions, were more important than the Gods. [\[note 27\]](#)

A few more lines on flowers, but now we turn to Jupiter:

"Then it was that the flower sprang up, wide open, to introduce the sin of Bolon-ti-ku [Jupiter]."

"(After) three years was the time when he said he did not come to create Bolon Dzacab [Mars] as the god in hell."

The "sin of Bolon-ti-ku" is a plasma display, but initiated by Jupiter, not Mars. This text seems out of place and recalls the final event of the Venus nova, except that mention is made here of Mars, not of Venus (as in the Mediterranean). In other chapters I have spelled out the details of how this event was differently seen and understood in Mexico from how it was seen and understood in Europe and Asia.

The sentence makes it clear that Jupiter, who was still considered the reigning God, has decided that Mars would not be the agent of death for the current creation, "the God of hell." As the Sun's electric field expanded outward into the region of the planets, it not only caused Venus and Mercury to blaze like suns, but Jupiter suddenly needed to adjust to a completely different electric potential. The flower which "sprang up" to initiate ("introduce") the plasmoid is the coma and funnel-like plasma extensions above and below the poles of Jupiter. This is clearly shown in the earliest iconography of the Olmecs, after 650 BC.

The eruption of Jupiter was followed by a plasmoid bolt ("the sin") directed toward the Sun, and although it was understood to be directed at Venus by the people of the Mediterranean region, it was understood to be directed at Mars by the people of Mesoamerica -- a difference of a half day in seeing the plasmoid land (or not seeing but guessing).

The timing of the plasmoid event was carefully preserved in the original documents and is here quoted by the *Chilam Balam*, probably as a matter of pride in how the cycles of the Tzolkin constituted high science. But the numbers initially do not add up.

"(After) three years.."

Mars was in inferior conjunction with Earth on February 22, 687 BC (-686 Julian). If we add three solar years (of 365.24 days), or Tun years (of 360 days), or even three Tzolkin cycles (of 260 days) to the last date that Mars was seen, we will pass beyond the year of the Venus and Mercury nova event in 685 BC. The word "after," however, was added by the translator, Roys. The sentence should have the meaning of "in the third year," in effect another inclusive span of time.

I certainly don't think we are dealing in solar years here, but in Tzolkin cycles instead. If we add just two Tzolkin cycles of 260 days, we reach July 25, 685 BC on the Gregorian calendar -- the traditional day before New Year's day of the Maya and Olmecs, and the day when the lightning bolt of Jupiter landed at the Sun. This is no mere coincidence. The records of the past as maintained by the Olmecs and subsequent Maya have proven to be dead accurate.

This is also the third instance of inclusive counting in reporting an interval. Since we are dealing with Mesoamerican concepts and language, we have to recognize that the first Tzolkin cycle is completed on the day after Mars was last seen on February 22, which is 6.3.2.15.16 14-Uo 1-Cib on the Long Count (August 13 correlation). The day of 1-Cib has to be counted, for it completes the previous Tzolkin cycle. This is how "three years" is arrived at. The "three years" represent an interval of 520 days, two Tzolkin cycles.

This reference to the 520-day interval is the fifth instance of chronological details of the events of the year 685 BC.

The text about Nine Fragrances starts with a shift to Katun 9-Ahau, the next in order after Katun 11-Ahau, when the first recorded approach by Mars was made (in 747 BC). This would propose that the nine descendings of Mercury are a count of both planets, extending only from 747 BC (the close of the previous Katun 11-Ahau) to 687 BC (the end of Katun 5-Ahau), where for the first and the last visit he is properly identified as Bolon Dzacab, Mars. That would extend the visitations to a total period of 60 years, ending with the last visit in 687 BC. The date of 687 BC (actually -686) is the year which Velikovsky had identified as the year of the second Earth shock received from Mars, although actually this last contact was by Mercury.

Reconsidering now the comment about Mars, it might be suggested that it was the sacrifice of Venus (Quetzalcoatl) which appeased (or controlled) Jupiter. This could certainly have set the tone for human sacrifices for the next 2000 years. Quetzalcoatl, Venus, not only died, but was fully expected to return from the dead, as Jupiter had done a number of times. The reappearance of the coma of Jupiter, which had not been seen since circa 2150 BC, had

demonstrated that. Jupiter, too, had died by fire.

Was the decision by Jupiter "not to end the world," or, as the "Chilam Balam" reads, "not to create Bolon Dzacab [Mars] as the god in hell," the promise of a new religion, a new religious practice, or a new contract between God and man? This certainly was the reaction in the Eastern Mediterranean region, as it was in China and India. Perhaps it was also understood this way by the later Maya who listened to the recital of this text that Kukulkan had been the savior of the world. This suggestion would be fully in line with the other couched references to Kukulkan -- Quetzalcoatl -- found in the remainder of the *Chilam Balam* text.

Saturn

The next section, which continues with descriptions of flowers, is, I feel, completely misplaced, perhaps placed here at an early time when the actual sequence of events was already no longer understood. I suspect that the following sections are from a source completely different from the text above.

What here follows is a portrait of Saturn from the earliest time in remotest antiquity. This is followed by a portrait of Jupiter. The portraits of the first two stationary Gods on their mats is deserved. The visitations made by Venus and Mars are ephemeral in comparison. It was Saturn and Jupiter who were the two supreme Gods who sat in rulership in the sky, a thousand years for Saturn, 4500 years for Jupiter, although during Jupiter's reign there were, as elsewhere in the world, numerous other Gods who acted as his agents or provide the role of intermediary. This is followed by a section which turns "rulership" over to the God of the Christians.

The portrait presented of Saturn is more than descriptive, for it records a sequence of events which is missing from the first description of Saturn at the start of this document: the changes from the time the bees blinded his face and the descent of fire and the rope, to the point of his demise at the hands of Jupiter in 3147 BC.

"Then descended Pizlimtec to take the flower [the root of the flower]; he took the figure of a hummingbird with green plumage on its breast, when he descended."

As will have been noticed, over the last few paragraphs the collection of events has been sorted topically into like images -- Mars followed water from heaven, and here the flower of Saturn in 4077 BC follows the flowers of Mercury in the 7th century BC.

Pizlimtec is the God of music and song, or a human revered as a musician. So says Roys. This might also represent one of Peratt's plasma instabilities represented by the Kokopelli petroglyphs, the flute player, which have been carved as petroglyphs and painted on cliffs worldwide. Except, of course, that here he is transformed into a quetzal bird.

The hummingbird with green plumage can be equated with Venus, although as an overall description of the bird on top of the central tree of heaven, and thus the whole Saturnian Polar Configuration. But in the limited context of this description, the "descent" is more likely the visual lowering of Uranus as the Earth started to take up an orbit more directly below Saturn. That started to happen perhaps as early as 5800 BC. Because of the smaller size of Uranus compared to Saturn (even with the considerable offset from the north pole of Neptune), by 4077 BC Uranus had probably disappeared visually behind Saturn.

"Then he sucked the honey from the flower with nine petals."

"Then the five-petaled flower took him for her husband, Thereupon the heart of the flower came forth to set itself in motion."

Uranus (if he is Pizlimtec) is male here. In the previous text he was identified as Saturn's sister. This suggests, of course, diverse sources for the *Chilam Balam* texts, or differing "readings" of the illustrations. The "heart of the flower" is Mars, which as we know from Mesopotamian and Egyptian texts, will start to lower toward Earth and wander away from the axis of Saturn.

The observation of a flower of nine or five petals, with Uranus lowering into the flower, taken together with the bees which initially wrapped the face of Oxlahun-ti-ku, Saturn, is a reminder of one of the oldest insignias of the pharaohs of Egypt, the bee and the sedge, neither of which has ever been explained as a symbolic source of power or majesty, and has only with difficulty been related by archaeologists to bees of Lower Egypt and the sedge of Upper Egypt (when it should be the other way around).

But a flower of nine and five petals can only be the much later plasma streams from Saturn to Mercury and thence to Mars, both located below Saturn, after Saturn went nova.

Or, following the next entry (see below), this might place the event (allowing Uranus to be seen as a distinct entity) much earlier than my estimate, well before the Earth had taken up a station below Saturn, for there is no other way to record the visual effect of seeing Uranus being lowered into Saturn. But it depends on how "and" and "then" are translated from the Mayan. We should also realize that the author was reading old books which conveyed little sense of the scope of time, so that 1000-year and 2000-year intervals passed unnoticed.

"Four-fold [four branched] was the plate of the flower, and Ah Kin Xocbiltun was set in the center."

Ah Kin Xocbiltun is Pizlimtec, claims Roys. But Bolio translates the last line as, *"When the chalice of this flower was opened, the Sun [Ah Kin Xocbiltun] was within and in its middle his name could be read."* The glyph for Sun, "Kin," looks like a flower with four petals and a small central circular area, like a four-petaled daisy. The dot in the center is Mercury. The sign or hieroglyphic for "Sun" used elsewhere in the world (Egypt, Mesopotamia, China) is a

circle with a central dot, but here we have the addition of four streams of plasma in arc mode impinging on Mercury and seen from below. It is amazing that the illustration from thousands of years ago was misread in this manner, but not totally unexpected.

"At this time Oxlahun-ti-ku [Saturn] came forth, but he did not know of the descent of the sin of the mat, when he came into his power."

"The flower was his mat, the flower was his chair."

The sin of the mat, again, is a plasma discharge to Earth. The flower mat resounds throughout other people's mythology too. The Gods of the Canopic jars of the dead pharaoh sit on a lotus flower, as do the creation Gods of the Hindus. The flower mat might be the rings of Saturn, or more likely is Mercury. I suspect that the previous line and most of what follows is placed here in the text to give reasons for why Saturn has to give up rulership at some point. The Maya of the *Chilam Balam* are notorious complainers.

"He sat in envy, he walked in envy. Envy was his plate, envy was his cup. There was envy in his heart, in his understanding, in his thought and in his speech."

"Ribald and insolent was his speech during his reign. At that time his food cries out, his drink cries out, from the corner of his mouth when he eats, from the back of his claw [hand] when he bites his food."

"He holds in his hand a piece of wood, he holds in his hand a stone."

The stone is Venus, the piece of wood is Uranus.

"Mighty are his teeth; his face is that of Lahun Chan, as he sits."

Lahun Chan is Mars as Ten Sky. The implied look is that of a red planet.

"Sin is (in) his face, in his speech, in his talk, in his understanding (and in) his walk."

"His eyes are blindfolded. He seizes, he demands as his right, the mat on which he sits during his reign."

"Forgotten is his father, forgotten is his mother, nor does his mother know her offspring."

As almost everywhere else in the world, there is no history before Saturn shows up. Thus he has no parents or has forgotten them. This more or less contradicts what is found on another page of the *Chilam Balam*, where, if not parents, at least there is a long lineage of sacred stones leading up to Oxlahun-ti-ku (Saturn), as the Christian God the Father. This is detailed in Book 11 of the *Chilam Balam*.

"The heart is on fire alone in the fatherless one who despises his father, in the motherless one."

His "heart is on fire" is an exact expression of the change to arc mode of Saturn, or descriptive of surface flames like are seen on the Sun.

"He shall walk abroad giving the appearance of one drunk, without understanding, in company with his father, in company with his mother."

The drunken walk is also recalled from Vedic sources which claim that Saturn traveled in a circle in the north sky. I cannot explain the sudden addition of the mother and father, unless this is another reference to Venus and Uranus.

"There is no virtue in him, there is no goodness in his heart, only a little on the tip of his tongue."

"He does not know in what manner his end is to come; nor does he know what will be the end of his reign, when the period of his power shall terminate."

Bolio translates the last few lines as:

"His heart burning only among the orphans, insulting his father, he must walk in the midst of the homeless, his countenance drunk, his understanding lost, to the place of his father and his mother. He has no kindness; there is no good in his heart; only a little bit on the tip of his tongue. He does not know how he must end up; he does not know what there will be at the end of his reign, or what is going to end in time with his power."

The drunken walk among the "orphans" and "homeless" catches the circular movement of Saturn ablaze in the middle of its satellites.

Before leaving this section, I should point out my suspicion that this extensive description of the faults of Saturn is starting to sound like a prophetic analog of a hoped-for fate for the Spanish invaders.

Jupiter

The following portrait is of Jupiter, but almost at once changes to a couched prediction of the return of Kukulkan.

"This is Bolon-ti-ku [Jupiter]."

This line reads as if it is a caption to an image in a codex.

"(Like that of) Bolon Chan [Lahun Chan is meant here] is the face of the ruler of men,

the two day [or, second] occupant of the mat and throne."

"The two day occupant" is, as before, probably a misreading of "second occupant" or "second reign," which would place the description as starting in 3147 BC.

Roys thinks that "Bolon Chan" ("Nine Sky") is a transcription error, since this name occurs nowhere else in any Maya documents or inscriptions, and that "Luhun Chan" ("Ten-Sky") was meant. "Ten-Sky," as I suggested above, is Mars after 3147 BC. "The face of" presumably just means "looks like," it does not mean "is." The concept, in fact, is that the face of Jupiter looks red, like Mars. This was probably not true initially, since at first, from 3147 BC to circa 2900 BC, Jupiter was green (or, at least so was the lower plasma expulsion). But on its return as a giant entity in the sky in about 2550 BC, it certainly was red. Bolio accepts Nine Sky as meaning "nine faces" and ends up with a reading of:

"These Nine gods ['Bolon-ti-ku,' Jupiter] will be manifested in nine faces ['Bolon Chan'] of Men-Kings, of the mat of the Second time, of the throne of the Second Time, came inside the 'beast Ahau Katun.'"

The *Chilam Balam* continues with the following, where Roys reads "beast" as "three":

"He came in Katun 3 Ahau."

I initially did not think that Jupiter was meant by "he" here. I thought the author was talking about Kukulcan and referring to the nova event of Venus in 685 BC, which falls in Katun 3-Ahau. But Bolio's "mat of the second time" or Roys's use of "two day throne" is probably meant as the second reign (not to be confused with creations), and thus the reign of Jupiter. What we are then being told here is that Jupiter reappeared in 685 BC in Katun 3-Ahau. That's true.

"After that there will be another lord of the land who will establish the law of another Katun, after the law of the lord of Katun 3-Ahau shall have run its course."

"At that time there shall be few children; then there shall be mourning among the Itza who speak our language brokenly."

"Industry (and) vigor finally take the place, in the first Tun (of the new Katun), of the sin of the Itza who speak our language brokenly."

The first Tun is the first 360-day period of the next Katun. It could be the next Katun after 685 BC, or it could be any Katun in the future. "Industry" had traditionally been attributed to the enterprising Itza.

"It is Bolon-ti-ku [Jupiter] who shall come to his end (with) the law of the lord of Katun 3-Ahau."

Take note of the three references to Katun 3-Ahau (and more below), and especially the line, *"After that there will be another lord of the land who will establish the law of another Katun, after the law of the lord of Katun 3-Ahau shall have run its course."* This is a veiled reference to the return of Quetzalcoatl, Kukulcan of the Maya, who disappeared in Katun 3-Ahau, but over the next few paragraphs this is turned into the God of the Christians. The "lord of Katun 3-Ahau" is Venus -- Kukulcan -- who shall, in time, that is, at some time in the future, end the reign of Jupiter, substituting another -- but not himself. This will fit history as it was played out with the arrival of the Spanish.

The End of History

A few lines of prediction, in effect incorporating the 16th-century condition of the conversion of the Maya to Christianity, complete the section. The prediction of another flood and the descent of Jesus on a cloud are perfectly in line with the history of the elder Gods.

"Then those of the lineage of the noble chiefs shall come into their own, with the other men of discretion and with those of the lineage of the chiefs."

"Their faces had been trampled on the ground, and they had been overthrown by the unrestrained upstarts of the day of the Katun, the son of evil and the offspring of the harlot, who were born when their day dawned in Katun 3-Ahau."

This is the fourth reference to Katun 3-Ahau. Some of these lines repeat text from the section "Interrogation of the Chiefs" elsewhere in the "Chilam Balam."

Bolio renders this a little more cohesively, although no clearer, as:

"When the Katun has ended, one will see the lineage of the noble Princes appear, and new wise men, and the descendants of the Princes whose faces were crumbled against the ground, who were insulted by the rage of the time by the crazy ones of their Katun, by the son of evil who called them "children of indolence"; those who were born when the Earth awoke, inside the Three Ahau Katun."

"When the Earth awoke in Katun 3-Ahau" is an interesting concept, and stands as the only reference to a change in the religious philosophy of Mesoamerica in the 7th century BC, although it is clearly demonstrated in the alignments of the ceremonial centers after 600 BC. No new alignments were ever added (except for additional alignments for 2349 BC).

Clearly also, in the above quoted paragraph, "those" refers to the Princes. In Roys's rendition it is not clear who "who were born" refers to -- it could be read as the "son of evil" and the "offspring of the harlot." Interestingly, this sort of language is to be found in the condemnations of Biblical prophets. The scribe thus betrays his Christian upbringing. From the very start of the Spanish overlordship the children of chiefs and officials were separated

from their parents and educated separately.

"When their day dawned" becomes, with Bolio, "when the Earth awoke." That in effect suggests a "fourth creation" as yet to come. [\[note 28\]](#)

Roys's text continues with an "end of creation" scenario:

"Thus shall end the power of those who are two-faced toward our Lord God."

"But when the law of the Katun shall have run its course, then God will bring about a great deluge again which will be the end of the world."

"When this is over, then our Lord Jesus Christ shall descend over the Valley of Jehoshaphat beside the town of Jerusalem where he redeemed us with his holy blood."

"He shall descend on a great cloud to bear true testimony that he was once obliged to suffer, stretched out on a cross of wood."

"Then shall descend in his great power and glory the true God who created heaven and earth and everything on earth. He shall descend to level off the world for the good and the bad, the conquerors (and) the captives."

Typically, once again there will be a new creation, for God will level off the world. The promised deluge, however, never came.

Recap of Book 10

It should be clear to the reader that this Book of the *Chilam Balam* is only tendentiously in chronological order, and, from our perspective, the mark is missed. The copyist did not have counts of Baktuns (periods of 20 Katuns) available or neglected them. This seems odd, for the texts of the Temple of the Cross at Palenque correctly place past events in the proper Baktun. Otherwise we would have to assume that, for example, the reason the events of 1492 BC and the events after 2349 BC (the "third creation") were listed in reverse order was simply to adhere to the late Maya historical format of lumping all events of the same-named Katun together.

Some chronological order exists, as in how the prehistory (the "second creation") is grouped at the beginning and in correct order, and the events of the 8th and 7th century BC are placed near the end (with the fall of the Absu in 2349 BC inexplicably added). And another form is used also. Events are sorted into activities and like imagery. Thus, near the end, all the flower episodes are grouped together.

The conclusion is reached compositionally, calling up the imagery of Kukulkan, starting with the event of the Sun going off its course in 685 BC. The ending reads as a subtle attempt to

simultaneously satisfy the politics of the new Christian overlords and not counter the traditions of the Maya citizens.

I have appended lists of Katuns for the time period of 3147 BC through 685 BC, with the events inserted. [\[note 29\]](#)

Special thanks to M Harris for corrections.

Endnotes

Note 1 --

The Maya, as well as other Mesoamerican people, certainly recognized the continuous progress of time along a single axis, as we do. So perhaps it would be more accurate to say that time was conceived of as the delivery of the separate Katuns, which carried with them certain qualities which predetermined the conditions of the world when a Katun arrived. This would be similar to recognizing the seasons of the year as a repeating cycle, where each month brings with it certain weather conditions. The "weather" of the Maya Katun cycle extended over twenty-year periods.

Note 2 --

Munro S. Edmonson, in "Some Postclassic Questions About The Classic Maya" (*Fifth Palenque Round Table*, 1978), writes about this:

"The Colonial texts produce the impression that their obscurity may have been partially designed to keep Maya traditions from the Spanish. They were not at all intended to be secret from the Maya peasantry, who are frequently apostrophized directly. And there are even now in Quintana Roo Mayas who can read and understand them."

But he immediately qualifies his opinion by pointing to an earlier tradition:

"It seems to me quite possible therefore that the glyphic texts of the Classic period could have contained a substantial esoteric and metaphoric element without necessarily impeding their intelligibility for the commoners and laymen to whom they must have been in part addressed. A certain deviousness and indirection may well be part of Mayan tradition. Flies are ancestors; the moon is the end; the sun is the beginning; stalks are lineages; monkeys are peasants."

My feeling is that Book 10 includes very little metaphorical material, although Book 11 and two other short pages of the *Chilam Balam* (dealing with earlier history) do, at a severe cost in understanding.

Amazingly, Richard Luxton in translation and commentary in *The Book of Chumayel* (1996), interprets all of Book 10 as a highly metaphorical poetical discourse on the political and social changes in the Yucatan in the late 16th century AD, based on a conflict and resolution between two calendars -- personified by Luxton as "The Thirteen" and "The Nine."

Book 11 does not escape this treatment either. I think this is nonsense created from the inability to make any sense of the texts. Luxton also frequently points up puns which make

no sense. However, he also has the ability to clear up many strange words, like "opilla" and "expleo." More on these in the following chapter.

[\[return to text\]](#)

Note 3 --

More recent archaeological finds have placed the first Maya monumental construction at 150 to 50 BC, and in some isolated cases as early as 800 BC (Takalik Abaj, in clay) and 600 BC (El Mirador, in stone).

Monuments raised in Palenque (in circa AD 700) present dates before 3114 BC, note celestial events in 2360 and 2305 BC, and record the birth of a "prehistoric king" of Palenque in 993 BC.

The first Tzolkin date inscriptions were in use at the Zapotec site of San José Mogote in the Oaxaca region by about 600 BC. By 400 BC the Tzolkin and Haab calendars were in use at Monte Alban (Oaxaca). The earliest Olmec long-count is depicted on Stele C from Tres Zapotes as 32 BC.

[\[return to text\]](#)

Note 4 --

The *Popol Vuh* clearly notes that the authors had used four source books, and, in fact, the *Popol Vuh* spends more than half of the text with descriptions of events from the first two books, called "The Dawn of Life" and "Our Place in the Shadows." This is not the case here for the *Chilam Balam*, although Book 11, and an additional page do specifically source these two.

Most of the information for Book 10 of the *Chilam Balam* seems to rely on abstracts from the last two books mentioned by the *Popol Vuh*, the book called "The Light that Came from Beside the Sea" and the book called "The Council Book." It would be expected that the Maya had already consolidated events by same-named Katuns, for this represents the layout of Book 10. It would also be expected that the significant event of 2349 BC, the fall of the Absu, would be sourced from a separate book. But this event is inexplicably split up to different sections of the text. Book 11 of the *Chilam Balam* treats the event of 2349 BC separately.

[\[return to text\]](#)

Note 5 --

In the *Popol Vuh* the tribal gods of the Quiche turn to stone when the Sun first shines. The Quiche continue to feed these stones with blood.

[\[return to text\]](#)

Note 6 --

Considering the bees as satellites holds if Saturn (and later Jupiter) were close enough to Earth to be seen clearly. There are enough references to the satellites of both of these planets among "mythological" sources from other parts of the world to confirm that this would have been the case.

I have only seen limited "bee iconography" among Olmec carvings or stelae, but there are some Maya murals depicting bees. Bees recur, however, in other pages of the *Chilam Balam* dealing with the history of much more remote times. There is an instance of wasps being used as weapons in the *Popol Vuh*, but this is likely a recollection of a particularly busy meteor shower.

[\[return to text\]](#)

Note 7 --

The prominent satellites of Saturn (those discovered before the 20th century AD) number 7. Adding Uranus, Neptune, Mercury, Mars, and Venus, and Saturn itself, the number adds up to 13. I originally (before 2010) excluded Neptune (as not visible) and Mercury (not discovered by me until 2009), and added Iapetus (at an orbital radius of 3,561,300 km) and Phoebe (orbiting at 12,952,000 km) to make up the count of 13. But I have removed these two distant satellites from consideration. Venus, although strictly a satellite, is not listed below, although included in the count. This is the count after 4077 BC when Venus was expelled from Saturn.

Moon	Radius (km)	Mass (kg)	Distance (km)	Discoverer	Date
-----	-----	-----	-----	-----	-----
(7 satellites known before the 19th century, in order...)					
Mimas	196	.380e+20	185,520	W. Herschel	1789
Enceladus	250	.840e+20	238,020	W. Herschel	1789
Tethys	530	7.55e+20	294,660	G. Cassini	1684
Dione	560	10.5e+20	377,400	G. Cassini	1684
Rhea	765	24.9e+20	527,040	G. Cassini	1672
Titan	2,575	1350.e+20	1,221,850	C. Huygens	1655
Hyperion	205x130x110	.177e+20	1,481,000	W. Bond	1848

Seven is the traditional number recognized in antiquity, as, for example, the "seven helpers of the king (Osiris)" in Egyptian mythology.

It was known in more remote antiquity among the Olmecs that Neptune was one of the stack of planets as related in Book 11 of the *Chilam Balam* -- See the chapter "The Earlier Olmec Record." Then the planets (Uranus, Neptune, Saturn, Venus, Mars) plus the "seven helpers of the king" add up to 12. It has long been my suspicion that Mercury should probably be added to the "Saturnian planets" to substitute for the globe identified as Venus and called "Sovereign Plumed Serpent" in the *Popol Vuh*.

The *Popol Vuh* identifies the northern planets as five in number during the time of the negotiations between the southern ball plasmoids and the northern planets (all within the period ending in 8347 BC, 2500 years after 10,900 BC), but the *Popol Vuh* seems to misidentify Mercury as Venus -- both were white spheres -- calling Mercury "Sovereign Plumed Serpent." This suggests that Venus only came into existence much later -- in 4077 BC.

[\[return to text\]](#)

Note 8 --

See Linda Schele and David Freidel, *A Forest of Kings* (1990). The temple images at Palenque are named as the "Tablet of the Foliated Cross," the "Tablet of the Cross (the World Tree)," and the "Tablet of the Sun (the War Stack)" -- in three separate temples of the same names, of which the "Temple of the Cross" is the central structure.

[Images: Palenque, circa AD 700. "Tablets of the Temple of the Foliated Cross," the "Temple of the Cross," and the "Temple of the Sun." After Linda Schele and David Freidel "A Forest of Kings" (1990).]

The tablets above are flanked with figures of the ruler Chan-Bahlum and his (dead) father. Both the accompanying texts and the iconography make it clear that the three panels are dedicated, in order (left to right), to Mars, Venus, and Jupiter. These are the "Palenque Triad" of gods, named GII, GI, and GIII.

The aged God L (GIII) on the left of the third panel above is Jupiter. God GI-prime, who is seen on the right of the panel, is Saturn, the father of GI (Venus). This last panel would seem to represent the lines of electrons connected to the far south as spears, not unlike the North African depiction of Neith of the Arrows. The two older Gods assigned to this would be appropriate, since this predated everything else, 5000 years ago.

[\[return to text\]](#)

Note 9 --

I have assumed a synchronous rotation Earth and Saturn, which means that in effect Saturn's period was 24 hours, not 10.6 hours which is the period of rotation today. The speeding up of the rotation of Saturn can probably be justified from the loss in orbital rotational momentum due to its later relocation to 9.5 AU.

What would certainly account for the "beating of things with wood and stone" would be a misalignment of the axis of Earth and Saturn, which I have estimated at about 15 degrees. Saturn would be seen as revolving in a circle of about 30 degrees diameter around the center of the Earth's polar axis on a daily basis.

[\[return to text\]](#)

Note 10 --

Wal Thornhill has suggested that the weak magnetic field of Mercury is probably due to its wildly eccentric orbit. This would also apply to Venus before it circularized.

[\[return to text\]](#)

Note 11 --

The easily seen satellites of Jupiter number 4. These are in excess of 3000 km in diameter and were noted by Galileo. The next four in size and prominence, ranging from 50 to 200 km in diameter were discovered by the beginning of the 20th century AD. The satellites are listed below in order of distance from Jupiter. There are many more small and odd satellites.

It should be suggested that the satellites of Jupiter seen in antiquity consisted only of those relatively close to the planet, large enough to be seen, and not at extreme distances. That suggests the numbered satellites listed above. Since Thebe was not discovered until 1979, it might be left off the list. Then "the nine" would consist of 8 numbered satellites plus Jupiter. This follows the same reasoning as for Saturn.

A number of mythological sources (Asia and Africa) claim nine satellites or Gods who accompany Jupiter. Maybe Thebe was included. The last four are all at 10,000,000 km or more, and are unlikely to be part of the set.

Satellite	Distance (km)	Radius (km)	Mass (kg)	Discoverer	Date	comment
Metis	128,000	20	9.56e16	Synnott	1979	close in, small
Adrastea	129,000	10	1.91e16	Jewitt	1979	close in, small
Amalthea	181,000	98	7.17e18	Barnard	1892	1
Thebe	222,000	50	7.77e17	Synnott	1979	too late
Io	422,000	1815	8.94e22	Galileo	1610	2
Europa	671,000	1569	4.80e22	Galileo	1610	3
Ganymede	1,070,000	2631	1.48e23	Galileo	1610	4
Callisto	1,883,000	2400	1.08e23	Galileo	1610	5
Himalia	11,480,000	93	9.56e18	Perrine	1904	6
Elara	11,737,000	38	7.77e17	Perrine	1905	7
Lysithea	11,720,000	18	7.77e16	Nicholson	1938	8
Leda	11,094,000	8	5.68e15	Kowal	1974	smallest
Pasiphae	23,500,000	25	1.91e17	Melotte	1908	too far
Sinope	23,700,000	18	7.77e16	Nicholson	1914	too far
Carme	22,600,000	20	9.56e16	Nicholson	1938	too far
Ananke	21,200,000	15	3.82e16	Nicholson	1951	too far

[\[return to text\]](#)

Note 12 --

See Linda Schele and David Freidel, *A Forest of Kings* (1990), and *Maya Cosmos* (1993).

The quetzal plumage is a plasma connection between Venus and Saturn. If the connection were in arc mode it would be a display in green or violet, or at any rate brilliantly colored -- like the feathers of the quetzal bird (*Pharomachrus mocinno*). At a later time it would be the green plasma tail of Venus.

[\[return to text\]](#)

Note 13 --

The two-headed serpent uses Venus as one head and the Sun as the other. This is an image of the plasmoid bolt of Jupiter as seen in July of 685 BC. The vision serpent is distinct from this and might be a representation of the last red ring in the sky, the snake Apep of the Egyptians. Alternately it might represent a polar plasma plume which showed periodically, and ended in a ball form with a feather headdress.

[\[return to text\]](#)

Note 14 --

Although it is possible that the "nine" of "Bolon Dzacab" refers to the rising of Mars to Saturn, which is specifically noted by the *Chilam Balam*, it is more likely that the "nine" refers to the nine close approaches of Mars in the era of 806 BC to 687 BC.

[\[return to text\]](#)

Note 15 --

It is just as possible that the contact was much closer to Mesoamerica, for it could be suggested that the north magnetic pole was located at or near Hudson Bay at this time. That would still have the location of the plasma contact be viewed in the northwest direction from England, in the northeast from Mongolia, but seen in the wrong direction from China (although Chinese myth is fuzzy on this). But the plasma connection to Saturn would present itself as directly over the North Pole as seen from Northern Pakistan and India -- and thus without the curvature as seen from other locations.

This view from India might be justified from the extensive use of really giant swings as religious monuments at a number of locations. Any plasma connection in glow mode would look to have well-defined left and right edges. As I have mentioned earlier, the plasma stream may have looked as if there was very little change in the width from its lowest to its highest location.

See, in this regard, Willard Van De Bogart's essay presented at [\[The Giant Swing\]](#). He writes:

"In India the swing has been used for thousands of years with its early beginnings going back to the aboriginal cultures which populated the Indian sub-continent long before the Hindu culture began. The swing has been used in fertility rites, religious rituals and as a symbol for the cosmological understanding of the universe and developed as a way to celebrate the beginnings of the New Year by cultures worldwide."

[\[return to text\]](#)

Note 16 --

Schele and Freidel, *A Forest of Kings* (1990), endnote 33 to page 246. To repeat a previous endnote: Ballcourt A-IIb at Copan in Honduras was built during the sixth or seventh century AD, and soon remodeled. The remodeling preserved three central alley markers.

A tree is shown on the outside area of the north and south markers. Suspended from each tree is a large playing ball. The tree of the north is labeled "Nine Successions"; the tree of the south is labeled "Seven Successions." If, as I suspect, the trees represent the plasma plumes of the north and south, then we have here an inventory of how many times the *axis mundi* reappeared. It would be appropriate to reappear more frequently in the north, since the north magnetic pole would facilitate a larger movement of electrons.

The dates for the return of the directional trees are as follows:

- (1) after 3147 BC (trees mentioned)
- (2) after 2349 BC (trees mentioned)
- (3) after 2193 BC
- (4) after 1492 BC (trees mentioned)
- (5) after 1442 BC
- (6) after 747 BC

- (7) after 686 BC
- (8) after 685 BC

The date of 686 BC is not at all certain. I added the date of 685 BC to the list. There was no change in the Earth's orbit in 686 or 685 BC, but the electric field of the Sun changed significantly in 685 BC. I also have the suspicion that there might have been two additional changes in the orbit of Earth between 2349 BC and 2193 BC, which have remained unrecorded. The name "Nine Successions" is one more "succession" than noted in the records at Palenque, where the first northern plasma plume is called "north-eight-house."

[\[return to text\]](#)

Note 17 --

The choppy transliterations of the dedicatory texts of monuments of the Maya seldom are very clear on purposes, except to prove the exceptional nature of the Long Count calendar. In this case, too, it is unknown why the "raised-up-sky north-eight-house GI" had to be invoked.

In the quoted text, the glyph "GI" is used with other modifiers, and it is uncertain what it would mean. It could be a possessive, "the eight-house of Venus." This would match the first recognition by the Egyptians of Venus flying around the tree of Biblos in the north. It could also read as "raised-up-sky north-house eight-GI," but GI (Venus) only shows up seven times near Earth, as I will detail in this text, not eight.

Maya representations of Gods as face-glyphs are called God GI, GII, GIII, and God A, B, C, etc., by archaeologists because it has not been easy to identify the faces with well-known and named Gods. But based solely on iconography I can readily associate some of these numbered and alphabetically identified face-glyphs with the planets as follows:

named God	planet
B, GI	Venus
D, GI-prime	Saturn
K, GII	Mars
L, GIII	Jupiter

Note 19 --

If Hathor in Egyptian iconography and literature can be identified with electric contacts by Venus, then the occurrence of the "Seven Hathors" (as sculpted, for example, at the Roman Period temple of Denderah in Egypt) might signify a similar recognition of the repeating nature of interferences by Venus.

In Copic "Hathor" is the name for the seven stars of the Pleiades.

[\[return to text\]](#)

Note 20 --

In the texts at the Maya Temples of the Cross in Palenque (AD 690), the Moon, although born before creation according to the texts (in 3121 BC) and bearing planetary children in 2360 BC, becomes "ruler" ("crowns herself") in 2305 BC. After correction (see below), this date would fall in a Katun 9-Ahau. Saturn is her husband; he is also born before the retrocalculated nominal date of the second creation of 3114 BC. The birth of the Moon can be attributed to seeing Jupiter on a nearby outer orbit before it clashed with the Saturnian system.

The specific seasonal dates used at Palenque are likely selected for their numerological value (so think some archaeologists), although I would think that probably the correct era was used -- that is, the correct Baktun and the correct Katun. The inscriptions were meant to be seen by local Ahobs and visiting dignitaries from other Maya ceremonial centers -- all of whom were literate and acquainted with the written history of the world.

That the three planets were "born" in 2360 BC would suggest that they became visible at this time, that is, as star-like objects, but more importantly it would mean that they were freed

from the obscuring Absu into which the ecliptic dipped for half of each year before 2349 BC. This could also suggest that the Absu had clearly disappeared at this time. As I have pointed out in another chapter, the date of 2360 BC is incorrect by 22 years. It should be 2337 BC, which places it after the "flood of Noah" of 2349 BC by 12 years. The "flood of Noah" is the start of the removal of the Absu from the skies.

The "corrections" noted in the text are based on the assumption that the Palenque dates were retrocalculated on the basis of a 365.24-day solar year, whereas the Olmec who instituted the Long Count originally used a 360-day solar year. Thus the retrocalculations place all the calculated Baktuns and Katuns too far into the past by 5.24 days per year since 747 BC.

The crowning of the Moon as Ahau in 2305 BC should be corrected by 22 years to 2283 BC, which, by the way, is close to the date that the Moon "Shun" joins the Chinese emperor (God) Yao (Jupiter) on the throne (2287 BC traditionally, corrected to 2277 BC).

[\[return to text\]](#)

Note 21 --

But note that in the chapter, "The Day of Kan," I identify Monte Alto in Guatemala, dating to about 2000 BC, as an earlier important ceremonial center. Monte Alto was destroyed or left behind after (what looks like) 520 years of use, to be replaced by San Lorenzo in about 1440 BC.

[\[return to text\]](#)

Note 22 --

An ephemeris program needs to be set at 2000 BC to show the Pleiades aligned with the intersection of the equatorial and the ecliptic. Except for the horizon and zero degrees longitude lines, this is the condition of the sky in June of 685 BC and anytime earlier. This would not be true after July of 685 BC, when the intersection had moved 15 degrees west along the horizon.

[\[return to text\]](#)

Note 23 --

The sweet smells are quoted by Velikovsky from the *Papyrus Anastasi*, Ginsberg's *Legends*, and the *Vedas*. It is reminiscent of the smell of the exhaust of diesel engines, thus the burning of hydrocarbons.

[\[return to text\]](#)

Note 24 --

July 26 is the day after July 25, and therefore is New Year's Day. July 25 represents the overhead passage of the Sun at Edzna in the Eastern Yucatan, as also at Teotihuacan in the

Central Valley of Mexico. Both are located at a latitude of 19 degrees and 41 minutes north.

At the time of the Spanish invasion, after AD 1556, July 26th was rotating through the days Kan, Muluc, Ix, and Cauac (using the August 13 correlation), reaching the day of Kan on July 26, 1557 (Gregorian), as Landa reported. But it would not have mattered what Tzolkin day-name fell on July 26th. It was known as "the day of Kan" -- as the day the world was destroyed and recreated.

[\[return to text\]](#)

Note 25 --

I attempted to apply any number of corrective measures to the calendar calculations, but only the substitution of 365.24 days for the 360 days, as assumed both by us and by the Classical Era Maya for the period prior to 747 BC, yielded results. Thus the scribal "error correction" for the day of Kan was accomplished well after 685 BC.

In researching the "day of Kan" over a span of 5000 years I became aware of how relatively easy it was to access the Long Count for particular combinations of the Tzolkin and Haab.

[\[return to text\]](#)

Note 26 --

We should be able to check locations of Mars and Mercury with an ephemeris program; however, fully accurate results cannot be expected, for even though the Earth's orbit was determined by 747 BC, the orbit of Mercury changed in 686 BC. The location of the planet Mercury for the date of March 23, -686, the second Earth shock, is "off" by some days, as I show in Appendix B, "The Celestial Mechanics." Since this is likely to have been the last alteration of the orbit of Mercury, it can be expected to be close to today's values in that instance only -- which represents the starting position (in fact, the aphelion) of the current orbit.

Earlier positions cannot be found for the simultaneous appearance of Mars and Mercury. This is to be expected for an ephemeris based on the current tight orbit of Mercury. It is amazing, yet expected, that a point of coincidence was found with the orbit of Earth in 686 BC. If the earlier orbit of Mercury was simply an elongated version of today's orbit, that is, the same orbit with extreme eccentricity, then the orbital period would be the same, although the location of the planet at any point in time along its orbit would vary considerably.

Certainly both Mars and Mercury would appear together in the skies on occasion, since Mercury (today) has a fairly short orbital period, and even Mars would pass Earth approximately every two years. An inspection of the series of the Julian (ephemeris) years 748, 733, 718, 703, and 688 BC, shows Mercury near the sky location of Mars in four out of five years in March or February. It does not happen in 688 BC but happens two years later. (The series was developed by repeatedly subtracting 15 years from astronomical year -747.)

I am adding this note only to demonstrate that the condition of the simultaneous appearance of Mars and Mercury is very possible. In all these cases an ephemeris program will show Mars outside the orbit of Earth and both Mars and Earth in line with the Sun.

[\[return to text\]](#)

Note 27 --

Schele and Freidel (in *A Forest of Kings*) are of the opinion that the accumulation of wealth, resulting from harvest surpluses and wider trading, which had come into effect after 300 BC (although earlier dates could very well be suggested), constituted an unprecedented crisis among the Maya, whose social interactions were based on egalitarianism. They write of "a culture which regarded the accumulation of wealth as an aberration," and note:

"We know that the problem the Maya were trying to resolve was one of social inequality because that is precisely the state of affairs that the institution of ahau defines as legitimate, necessary, and intrinsic to the order of the cosmos."

Acceptance of this social sinkhole for wealth did not keep Maya scribes from complaining incessantly, as we see in the *Chilam Balam* texts, both in this Book and elsewhere.

The surpluses of maize, by the way, are astounding. Typically, in well-watered territory, only one-third of the corn crop was needed to feed the family of the farmer year round -- a family which could easily consist of 10 people. That means 20 people could be fed for a year from the remaining crop.

[\[return to text\]](#)

Note 28 --

If we assume that the "lineage of the noble chiefs" and those whose "faces had been trampled on the ground" represent the orthodox upholders of the relationship between the Maya and the cosmos, then the "unrestrained upstarts of the day and of the Katun," who had inflicted the overthrow of the orthodox nobility, most likely represent a second wave of religious philosophy entering the Yucatan from the west.

The archaeological record of the Classical Era shows the arrival of emissaries from Teotihuacan (in Mexico) some time before AD 700. They bring the flayed human face shield and the dart thrower, which were in general use in the Valley of Mexico at that time. The Maya adopted these to some degree, but it is more likely that they adopted aspects of the religious philosophy and practices of the westerners.

Of course the Maya had already adopted both the temple mound and the script and time keeping of the Olmecs by circa 100 BC (and possibly much earlier). And the later invasion by the Itza, after AD 900, certainly brought with them a religion of hope for the return of Quetzalcoatl which differed from the concept about Venus which the Classical Maya had

already established.

In the main text I have postulated the changes in attitudes toward the older Gods in China, India, and the Middle East after 600 BC, which spread in waves of new religions. I have suggested that the same would have happened in Mesoamerica, and would propose that the first and primary epicenter was Olmec Veracruz.

It could therefore be suggested that, as elsewhere in the world, a number of different solutions came forward. We certainly see this in Central Mexico in the period after 600 BC, with new interpretations of the control of the Gods established at intervals through to the time of the Aztecs.

We have no clear idea from the text of the *Chilam Balam* of when new philosophies were introduced which would have caused the overthrow of the older nobility, although the Itza are repeatedly blamed for "introducing idolatry" to the Yucatan, possibly to cast blame away from the indigenous Maya. But what is interesting is that this is referenced to the events Katun 3-Ahau -- in 685 BC. Since Katun 3-Ahau would repeat, any number of other incidents could be tied to this. This history certainly holds Katun 3-Ahau as significant.

[\[return to text\]](#)

Note 29 --

The following lists every one of the ending years of Katun 9-Ahau, 7-Ahau, 5-Ahau, and 3-Ahau. I have listed the years as "BC" rather than in their astronomical nomenclature. The Katuns all start 20 years earlier. Where I skip a range of Katuns, I have placed a series of dots.

The corrections listed on the right of some lines are based on the assumption that the Olmecs had listings of Baktuns and Katuns available which reflected solar years, so that a Baktun would be 400 solar years, and a Katun would be 20 solar years, without regard to the actual length of the year. Thus the corrections below are based on subtracting 6 Baktuns (2400 years) from 747 BC to arrive at 3147 as the year of the end of the "Era of the Gods." The correction is thus **3147 - 400 * Baktuns - 20 * Katuns**. The corrected years are shown as "sb" -- "should be."

The Olmec Record of the Past

This chapter will turn out to be dense, obtuse, boring, and unbelievable since we will be dealing with records dating back to 41,000 years ago. I would not make this statement, if I had not seen verification of this against the record of residual Carbon-14 dating back 50,000 years (which was noted in the chapter "Event of the Younger Dryas"), where the Carbon-14 information is from original data by A.H.L. Voelker, et alii, in 1998.

What the earlier chapter, initially written after this chapter, describes is the following:

In the Maya *Chilam Balam* there is a record of seven sightings of "stones" representing God the Father who was attempting to come into existence. The stones are apparently the Saturnian stack of planets. Enormous spans of time are indicated between approaches of these stones, although more likely "approaches" should be understood as the time of the leave-takings.

In the chapter "The Olmec Record of the Past" [this chapter], written long before the chapter "Event of the Younger Dryas", I had initially suggested that the *Chilam Balam* record might go back 30,000 or 40,000 years. I would now suggest that this record starts in 41,000 BC. At that time Australia and Southeast Asia were assaulted with an electrical contact from Saturn. The megafauna of Australia and Southeast Asia went extinct.

If this information could be correlated to glaciation and Ice Age temperatures over the last 50,000 years, it might suggest that Earth was captured and released by Saturn seven times before the last event (the Younger Dryas). The temporary capture meets the conditions suggested by Tom Van Flandern, and also follows his suggestion that such capture could be temporary -- although measured in thousands of years.

This history is recorded in Book 11 of the *Chilam Balam*, which has to be the most arcane and twisted narrative of the whole of the *Chilam Balam*. It took me over six months to get through the text, line by line, spending an hour a day inquiring into meaning, comparing translations, and associating it to a sequence of known events. Two years after that I was still adding notes from Richard Luxton's *The Book of Chumayel* (1996). A copy of Book 11 is available locally at [\[saturniancosmology.org/book11.htm\]](http://saturniancosmology.org/book11.htm).

But before I was done, I realized that I was looking at records dating back some 30,000 or 40,000 years. Of course it is astounding to suggest that a Mesoamerican tribe, still living in the "Stone Age" in AD 1500, had records dating back to long before those of any other people on Earth. I'll detail the reasoning behind my conviction for this further below. When, however, we see the details of site alignments in Veracruz and the Valley of Mexico since 1400 BC, the suggestion of the existence of such extensive records gains credence as but another aspect of the intellectual abilities of these people.

What is being described in these pages of the *Chilam Balam*? Let me again emphasize that we are reading texts which are interpretations of what was seen depicted in ancient bark-book codexes. The readings were made by people who had absolutely no idea what most of the depictions and the later added glyphic texts were about. Their only concern was the faithful transmission of sacred history. Today we know more than they did. We can trace events and describe phenomena which remained a total enigma to the readers of the bark-books in the 16th century AD, and probably most others who had looked at these ancient records over the previous 10,000 or 20,000 years.

Introduction

There are three tasks ahead, and three documents:

(1) I will start with an attempt to "read" Book 11 of the *Chilam Balam* in terms of the chronology of celestial events which I had already established on the basis of information from the European Upper Paleolithic between 31,000 BC and about 10,000 BC, plus the implications of what was seen in the skies, based on the changes in figurines to 4077 BC.

(2) Then follows a single page titled (by me), "A Survey of the World," which describes events after 10,900 BC. This is also the opening page to the *Chilam Balam*. Part of this was described in the chapter "The Peratt Column and the First Gods."

(3) An additional single page, "The Third Creation" of 2349 BC (an event which is also presented in Book 10), will be addressed last.

The books of the *Chilam Balam* were kept from the eyes of the Christian priests, were recited at town meetings, and recopied for some 300 years. As public documents, these had to retain their accuracy, even if the writers did not understand what any of the descriptions portrayed. It was history, very old history, and very certain history, which reached back thousands of years before any history brought by the Spanish invaders. The books described past events in graphics, and were thus indisputable as a record of what had been seen. Moreover, the books not only told of the past, but predicted the future. The coming of the Spanish had been known long before they arrived.

I suspect that the Books had circulated in graphic form among many tribes before any text was added after about 600 BC (and perhaps at Monte Alban). That would certainly explain some notable differences in interpretation of events of the remote past, which show up both in the *Chilam Balam* and in the *Popol Vuh*. There were thus likely many versions of the original codexes, many distinct derivations of the memories of diverse tribes, although the histories of the remote past are generally cohesive to the sequence of events I have established so far in the text of these pages. The differences in interpretation, which is a difference in "readings" performed in antiquity, show up because Books 10, 11, and the other two loose pages repeat some of the same events.

(1) BEFORE CREATION

In Book 11 of the *Chilam Balam*, titled by Roys as "The Ritual of the Angels" and by Bolio as "Book of the Spirits," there is recorded a sequence of events which nominally concerns the birth of the Christian God, the Trinity, and the angels. It looks to be in correct order of events, if by "events" we mean what was seen in the skies of Earth during the period before about 10,900 BC, and probably as early as 41,000 BC. This was rather astounding to me, but this

section parallels the sequence of images which I had assembled earlier in the chapter "Saturn and Archaeology" on the basis of archaeological information, and augmented with information on the peaks in Carbon-14 fractional differences (from the current measures) in Iceland marine sediment and the details of the Peratt column of 10,900 BC to 8347 BC.

The "Ritual of the Angels" is heavily Christianized. We meet God the Father, the Trinity, and other beings who are part of a Christian theology, but they are conformed to the facts of history as the Maya had recorded them. Thus instead of God the Father existing from all time before the beginning of creation, he calls himself into being -- creates himself -- well after the beginning of time, and officiates over the creation of the world. Most of this, not unfamiliar from mythology worldwide, can parallel Christian theology, but there are some remarkable differences, which would have irked Catholic theologians of the 16th century AD. Before he comes into existence, for example, God the Father resides in a stone.

What is also constantly repeated is the notion that most of the events described in Book 11 happen when "there was neither heaven nor earth." It is a notion expressed by the creation myths of many other people, that creation happened when Saturn started to blaze and the Gods and their land showed up.

There was a considerable congruence between Maya or Mesoamerican concepts of spirituality, grace, and heaven and hell and those of Christianity, so that the Maya and Aztecs easily adopted the Catholic saints and feast days, for example. It is important to realize that the Maya (and probably the other people of Mesoamerica) considered the maize plant to be a free gift of the Gods. And it is. Maize is the most productive and easily managed grain in the world. This is congruent with the Christian concept of grace, as a free gift. Newly sprouting maize plants were called "gracia."

However, the concept of "heaven" as an imagined space might have been elusive, unless that space was delineated with specific objects. Edward T. Hall, in *The Hidden Dimension* (1966), has pointed out for the Hopi, "[they] cannot, as we think of it, 'imagine' a place such as the missionary's heaven or hell." As for American Indians of the Southwest, so for the Maya, who shared a similar language base.

What we see in "The Ritual of the Angels" is an attempt to bring a new Christian theology, which had no basis in concrete objects, into congruence with the known pre-history of the Maya. The objects in the sky, the sacred stones, sketched in the oldest books of Mesoamerica, were an historical record based on observations, and thus real. The birth of the Christian God could perhaps be deduced from the Maya's history of the deep past. This is what Book 11 attempts to do.

A 40,000 year record

In terms of a history of celestial events dating back tens of thousands of years, it is perhaps

not unexpected that the *Popol Vuh* covers elements from the same period, but in a popularized narrative form, and frequently out of order. I'll discuss the *Popol Vuh* later, but I should make note of the fact that three-quarters of the narrative of the *Popol Vuh* is spent discussing the same extremely long time period.

Modern translators are hampered by the fact that they do not understand a single word of the text in terms of a meaningful context. Who would have guessed that the Maya scribe was relating events as seen and understood 7000 and 40,000 years ago? Even the original Maya copyist would have had problems interpreting the graphics before him. This is clearly seen in the wide variety of imagery with which these events are retold, in this Book 11, in Book 10, in the two loose pages, the Palenque engravings, and in the *Popol Vuh*. Allowing for diverse readings, the events can still be recognized. There is a remarkable consistency in the sequencing.

In terms of what was already known before I started to look at Book 11 of the *Chilam Balam*, the following list could be made and compared with this text:

- (A) The cup and tail marks before 30,000 years ago.
- (B) The classical Venus Figurines after 28,000 years ago.
- (C) The Younger Dryas, 10,900 to circa 9500 BC.
- (D) The chaos of Saturn after 9000 BC.
- (E) The Peratt column of 10,900 to 8347 BC.
- (F) The Peratt column instabilities.
- (G) The nova event of Saturn of 4077 BC.
- (H) Creation of the rings.
- (I) The assembly of God's heaven.
- (J) The recognition of Mars below Saturn.
- (K) The plasma dome at the north horizon.
- (L) The lowering of Mars to Earth.
- (M) The end of the first creation.

It is this list which is maintained in Book 11 without interruption to furnish a narrative sequence. Let me give a short synopsis of each of these events, as follows, before jumping into a longer textual analysis.

(A) The cup and tail marks, before 30,000 years ago.

As far as we can tell, before the European Gravettian period of the Upper Paleolithic, and thus before about 28,000 years ago, we see the ubiquitous cup and tail marking inscribed on rocks and cave walls worldwide. The best dating suggests that these marks start about 40,000 years ago, and appear again 20,000 years later. These are gross estimates of time; there is no finer detail. [\[note 1\]](#)

Book 11 identifies these marks as the "three-cornered precious stone of grace" -- a metaphor

for a maize kernel -- a term probably applied interpretively thousands of years later. Some seven separate appearances are noted, each appearance happening "when there was infinite night, when there was no God." The "infinite night" might also have been retroactively applied. A period of 1500 years of considerable shadow was experienced in the Younger Dryas, and might have been applied to the graphical record of the appearances of the "three-cornered stones" because probably nothing else was recorded at the same time. Bolio, by the way, notes these stones to be on fire, as "flames." That would both explain the reason to record these incidents as well as the shape of a line extending from a lozenge or oval.

The description seems to suggest that there was no daylight, but daylight would not have been a likely part of the record. The graphic record was of two planets in arc mode plasma connection -- probably seen at night. The implication of endless night without daylight, however, fits the overall theme of the narrative, which is the establishment of day and night (and heaven and Earth) at the start of creation.

(B) The classical Venus Figurines, after 28,000 years ago.

The classical Venus Figurines appear in Europe in the Gravettian period of 28,000 to 24,000 years before the present. Of note is the fact that figurines are not recognized by the Olmecs (or have remained unrecognized by us), although female figurines occur among other Central American tribes, as late as 2400 BC. The Olmecs saw stones. In their words, these were sacred stones. In this case, and as distinct from descriptions from later paragraphs, the stones are seen as "three generations suddenly augmented in stature" -- which likely represented Uranus, Neptune, and Saturn (with possibly Mars, below). (This could also be interpreted as the three southern ball plasmoids.)

Bolio has a considerably different reading, including "... he of one Age alone, the Very Tall," which seems to skip directly into the elongated figurines of the European Magdalenian period (17,000 to 14,000 years ago). In Europe the figurines disappear for some 7,000 to 10,000 years between the earlier Gravettian and the Magdalenian. This may be the result of an abandonment of Western Europe during a period of increased glaciation, although caves (in Spain and Southern France) continued to be decorated throughout this period as far as I can tell from tabulations I have made.

(C) The darkness of the Younger Dryas, after 10,900 BC.

The shadow of the Younger Dryas, from 10,900 to circa 9500 BC, is mentioned three times, in passing, during the description of (what I assume is) the Saturnian stack of planets. It is even named as "Nilu," which Roys suggests is a reference to the plague of darkness at the time of Exodus. The *Popol Vuh* describes this period extensively, not only the darkness ("before creation") but also the cold and freezing rains. The text of Book 11 does not. Much more text is spent describing the seven pointed stones since 40,000 years ago.

(D) The chaos of Saturn, after 9000 BC.

It is uncertain when the obscuring clouds appeared or were seen, or how long this lasted. Other mythologies simply have the clouds of chaos appear after the darkness. Book 11 does not neglect the mention of obscuring clouds, called "winds," by naming six winds in a single paragraph. With this the form in the sky was obscured, "he covered the name of the holy heaven."

The Earth at this time was dropping down further below Saturn and was being drawn toward the rotational axis of Saturn, to eventually be relocated to below Saturn's south geographic pole -- a process which would take several thousand years. The chaos, the swirling clouds, was the enclosing coma of Saturn. In dropping below Saturn, the Earth entered into this glow mode plasma coma of Saturn.

(E) The Peratt column, between 10,900 to 8347 BC.

Hardly to be missed, the "beast" (opossum, "white beast") and its tail are mentioned, as well as the establishment of three stones below the feet (or in the "dust" of) the "One Stone." This suggests that Saturn was seen in the north, or at least the terminal location of the tube of plasma could be located, probably as a circular pattern. The Olmecs knew what that was. They had records.

(F) The Peratt column instabilities.

In the following paragraphs something is happening in the skies, but the only recognizable figure is a "giant" who appears. The plasmoid of the Peratt Column was interpreted as the body and face of a giant in the skies in Australia and additionally in Mesopotamia (as Oannes) and at Lepenski Vir in Serbia as a woman, although the dates are way too late for Lepenski Vir. This could be this giant, but as likely it is the "squatting man" instability of the Peratt column also mentioned in the Norse *Elder Edda* as existing in the south.

(G) The nova event of Saturn, 4077 BC.

Suddenly we have notice of a fire in the heavens, and as emanating from a single object, "This was one grace, one stone; then fire was created." This is not some legendary discovery of fire by humans, this is a fire in the sky, as suggested by the phrasing, "... the light from that which lighted the heaven" and "... after the light originated in the heavens." This is the most recent nova event of Saturn.

(H) The creation of the rings.

As part of the nova change of Saturn, a bundle of plasma in arc mode was established to Mars via Mercury, noted as the "creation of the star" (at Mercury), and the rings of Saturn would have shown up. The rings are here separately listed by color, following, of course, the colors of the later directional trees, but directions are not mentioned.

There is no indication of how long the arc mode contact with Mercury and Mars (and Earth) lasted, and no mention of this process is ever repeated. From the creation of henges in Northwestern Europe, it would seem that arc mode plasma contacts were experienced periodically, although it is difficult to know anything of this for certain. The next set of sentences identifies a plasma stream in glow mode.

(I) The assembly of God's heaven.

The next sentence describes Saturn as a God, like Oxlahun-ti-ku, or like the pharaoh as Horus of the Narmer Palette -- *"grasping in his hand his stone, grasping his 'cangel' [dragon], grasping his wheel on which are hung the four angels of the winds."*

There is no question that this represents the image in the north skies shortly after 4077 BC, but there is nothing Christian about this. It is the original chief God of the Olmecs and Maya.

I am skipping (J) and (K) the details of which are listed below.

(L) The lowering of Mars to Earth.

This recounts the lowering of Mars to Earth. In effect this creates the world. The plasma dome (or dome of water vapor) in the northeast (or north) is described as a mountain or a monument base. "Holes" are bored in the mountain, suggesting that, from the latitude of Guatemala, Mars would have been seen as disappearing behind the "mountain" -- "occluded" might be a better description. The holes in the mountain presumably are the fluted areas, hinted at earlier. These are also the "caves" from which humanity sprang in other Mesoamerican and South American creation myths.

(M) The end of the first creation.

This "first creation" ends in the disappearance (being "bitten") of the Sun. The author places this in Katun 13-Ahau, as a way of emphasizing the predictive value of this Katun. In fact, the text segues directly to a description of the forced Christianization in the 16th century AD. To underscore this understanding, the text ends -- in a different hand -- with the date of AD 1539, and signed "Chilam Balam, the prophet."

Following is a more descriptive exposition of the text, by distinct familiar topics.

The Three-Cornered Stone

The following is the translation by Roys. It is labeled as Book 11, "The Ritual of the Angels," and is as obtuse and opaque to interpretation as Book 10.

"'Dominus vobiscum' ended the words of their song when there was neither heaven nor earth."

*"When the world was submerged, when there was neither heaven nor earth, the **three-cornered precious stone of grace** was born, after the divinity of the ruler was created (declared), when there was no heaven."*

*"Then there were born **seven Tuns, seven Katuns**, hanging in the heart of the wind [in the heart of the spirit], the **seven chosen ones**."*

Bolio has "seven chosen flames" for "seven chosen ones." Roys interprets "tun" as a holy stone, and "three-cornered precious stone" as symbolic of the maize kernel, writing:

"Maya 'tun': This usually means a precious stone, while an ordinary stone or rock is called Tunich. 'Tun' also means the pit of a fruit as well as the soft surface limestone of the country. In compound words designating things made of stone we find the same term employed; furthermore 'tun' is the name of the Maya time-period of 365 days." [He means 360 days.]

"It is important to the interpretation of this text to note that among the Maya the Spanish word 'gracia', here literally translated as 'grace', is a ritualistic term employed to designate the young maize plant. Consequently the 'three-cornered precious stone of grace' is doubtless also a liturgical term indicating a grain of corn [maize]."

It is interesting that at first "the world" was "submerged" -- but at a time before heaven and earth. The "earth" and "the world" apparently are different. It suggests, as the *Popol Vuh* does also, that there was only some undefined substance before creation. The phrase "the heart of the wind" is reminiscent of the titles "Heart of Sky, Heart of Land" and "Heart of Sea, Heart of Lake" of the two sets of Gods of the *Popol Vuh* or their location. Since these were the sky above the far south horizon, seen above the land, and the "lake" above the far north horizon, seen above the sea, it suggests that the "heart of wind" is the center of vapors, clouds, or sky - assuming that "heart" denotes "center," or, more likely, a central site of an activity. As I have pointed out earlier (in the chapter "The Peratt Column"), these two sets of objects rotated into view from below the horizon (both the south and the north) on a daily basis. But all of that was much later in time.

I would assume that the "three-cornered precious stone" that we are dealing with here is some object seen in the skies and on the basis of what develops later I would suggest that most likely it would be traveling on the ecliptic. It could, however, have appeared anywhere in the sky.

What the seven "tuns" or "Katuns" really are, is not clear. From Bolio's suggested translation as "seven chosen flames" it might be that these describe the cup and tail form of Saturn in arc mode plasma contact to Mars, as I have suggested earlier (in the chapter "Saturn and Archaeology"). More on this below.

I should also note that the number "7" had no particular mystical meaning in Mesoamerica,

although it is a significant number in Christianity (representing, among other things, the 7 planets of antiquity, and, of course, the six or seven days of creation). Luxton suggests that these 7 instances of stones represent the seven days of creation of the Bible. Luxton tends to metaphorical and poetic explanations. But there is no narrative of a piecemeal creation, as we see in the Bible, and creation in the Bible took only six days. I might suggest the exact opposite, that the Bible is based on these seven recalled events, instead.

If the scribe were making things up, the number "13" would have been used instead. Adding God the Father to the historic record (as is done further below) is also only a matter of reinterpreting historic evidence. It does not involve inventing something new. [\[note 2\]](#)

The sightings of the "seven stones" seem to span a limited period of years. Each sighting probably lasted only a brief period, at most for a decade (the estimate of 1500 years, at an earlier time, seems not to have been valid anymore), with long stretches of time between appearances of the stones. The span of time is set out at the opening paragraph, *"Then there were born seven Tuns, seven Katuns... ."* A "tun" is a stone and also a year. A "Katun" is 20 years. This could make it look as if the "seven stones" were seen over a period of one Katun each. This would support my assumption that Saturn was only seen as on fire for a brief time, the time where Saturn was closer to the Sun, as comets do today.

The following text of Book 11 will point that up, when both the stones and the nights are called "infinite." I will suggest that the scribes are using "infinite stone" for "Baktun" periods (which is how "Baktun" is defined: a measure of 400 years). The Katun and Baktun were the standard time-keeping measures among the Maya (and earlier Olmecs), in the same manner that we use decades and centuries to point to events of the past.

The first hint that here we are dealing with a much deeper history was the apparent references to the cup and tail marks. We have to keep in mind that the cup and tail marks were carved worldwide in profusion since remote antiquity. The sight of the flaming planets must have been absolutely spectacular to the humans observing them. It suggests repeated appearances of Saturn with long periods in between.

I am here equating the periodic appearances of this stone to the movement of the object on a cometary orbit, except that there does not seem to be much regularity in its repeated returns. I believe this object is Saturn, traveling with at least Mars below its south pole.

Book 11 of the *Chilam Balam* continues:

"Then, they say, their seven graces stirred also. Seven also were their holy images. While they were still untarnished, occurred the birth of the first precious stone of grace, the first infinite (innumerable) grace, when there was infinite night, when there was no God. Not yet had he received his Godhead."

There is no question where we are in time -- it is before the birth of God. This fact will be

repeated a total of seven times in the following text. The Maya were so convinced of the validity of their illustrated history books, that they attempted to fit the Christian God into their narrative history on their terms.

"Then he remained alone within the grace, within the night, when there was neither heaven nor earth. Then he departed (buki) at the end of the Katun, as he could not be born in the first Katun. There were his long locks of hair, 'adeu ti paramii'; his divinity came to him when he departed."

I have the suspicion that "his divinity" might be the development of an arc mode plasma expulsion at the surface of Mars. Saturn would have entered the Solar System with a coma surrounding the stack of planets. This is the behavior of a comet, but as becomes clear, without a tail. Only on getting closer to the Sun would the arc to Mars have developed. Mercury was not part of the stack at this time yet, so the arc connected directly to Mars.

As I have noted elsewhere, the image of Saturn at the time of the European Gravettian period, was in the shape of a woman -- the Fat Lady. It did not have a bow shock or a tail. All the looks of the figurines are of a closely fitting coma in glow mode -- where "closely fitting" still involved distances of up to an estimated 2 million miles (3 million km).

Saturn came from outside the Solar System, positively charged, for it was a star. From this it would seem obvious that Saturn on these infrequent incursions into the inner reaches of the Solar System would not form a giant coma like what would be expected for an ordinary comet, or a tail 100 million miles (160 million km) long, as we see today. A comet needs to get rid of electrons. If Saturn had had a cometary tail it would have been seen when Saturn was in the eastern or western sky. But a tail is never depicted among the million on millions of Venus Figurines of antiquity. This is easily explained by the fact that Saturn, along with its companion planets, was at a much higher positive charge level, having originated outside the Solar system. Saturn was faced with the need to scavenge for electrons to reduce its positive electric potential.

These incursions into the inner reaches of the Solar System were as infrequent as 4000 years apart. Only during a short period of this would Saturn been seen to approach, perhaps for a decade. This was no ordinary comet which would show only for some months. This was an object that approached for hundreds of years, and on getting closer would light on fire to something below the main object. Then it departed again into total obscurity -- getting smaller year by year. [\[note 3\]](#)

I am suggesting, therefore, that, during the middle portion of the journey of Saturn through the Solar System (which would include leaving), it would suddenly switch to arc mode. This is the suggested solution of the phrasing "his divinity came to him when he departed." It would seem strange that the beings of the stones only became god-like when they left unless something suggested this, keeping in mind also the particular grammar which recognizes only ongoing and completed action. For Saturn to go into arc mode is the obvious solution,

for a closer approach to the Sun would require a greater adjustment in electric potential, as also happens with comets. The other seven stones (appearances), except for some textual abbreviation by the transcriber, offer the same solution of "and he obtained his divinity when he left," or words like that.

About "adeu ti paramii" Roys notes this book is filled with Spanish and Latin words heard in the Christian church service. He also writes, "Here 'buki' is translated as though it were 'luki', he departed. 'Buki' means to be beaten up." Roys further suggests that, "the 'long locks of hair' are probably a reference to the corn-silk," except, of course, that these appearances happen some 30,000 years before the introduction of maize.

I disagree with the corn-silk reading of the "long hair." I would suspect that this might be a reference to Uranus, seen above Saturn. This was seen, noted once, and not repeated for the other appearances.

"Departed" is probably appropriate (as "luki"), for the same happens to all the following "precious stones." At first I thought that the seven stones might be describing constituent parts of the stack of Saturnian planets, but these add up to five (at best, and later), not seven.

There are seven stones, each of which appear in the "infinite night," wake up, and then disappear again into the "infinite night" having "obtained their godhead" before leaving. I think that the "infinite night" is an element displaced into this narrative of the remote past from the era of 10,900 to 9000 BC when the Earth was in shadow (although a similar condition could have been experienced at 41,000 bp). It might be suggested to later readers of the original codexes that the fifteen hundred years of darkness between 10,900 and 9000 BC certainly must have pertained from the very beginnings of creation, especially since there was a later well-known lighting up -- a creation event. In suggesting this I am in violation of my supposition that the authenticity of these documents was carefully guarded as we see with myths worldwide. But in this case I think the records span some 40,000 years. It may be that text was added only after about 600 BC. At that point in time the original context of the events would have been hopelessly lost.

Earlier I suggested that these repeated visitations of the stones were probably the seven instances when the Carbon-14 differential rose to a peak -- between 41,000 bp and 13,000 bp. I will stand by that supposition, especially once I realized the coincidence in time between a long disappearance of the Venus Figurines and a very long interval between two of the Carbon-14 peaks.

These visits of Saturn were long lasting, they certainly were spectacular, and were the only thing of interest during generations-long periods. The fact that the last stone, the 8th, actually woke up and caused additional phenomena was reason to keep a record of the previous attempts. [\[note 4\]](#)

At any rate, I think what we are looking at here are events long before what is known as "the

first creation" starting in 10,900 BC. The "three-cornered stone" is likely to represent Saturn, in arc mode with the sharp third corner (Mars) pointing down, in the form elsewhere depicted as the "cup and tail" form. This would be before the first cultivation of maize, or at least before a time, 8000 BC, when maize cobs were no larger than an inch in length. But by the end of Book 11 the "three-cornered stone" will be equated with maize (at least, in Roys's reading of the text).

The "three-cornered stone" thus becomes one of a number of datapoints which could be used to produce a chronology for Book 11. But the "cup and tail" form is poorly dated throughout the world. The "cup and tail" form, as I have indicated earlier, is an indication that Earth was located too far from the Saturnian planets to make a sensible distinction of the individual elements, but that Mars was located close below Saturn and being etched by a continuous electrical arc. I have earlier placed this event at 40,000 to 30,000 years ago, at the start of the European Gravettian period, since by 28,000 BC the first classical Venus Figurines show up.

What I am suggesting here is that the predecessors of the Olmecs had significant continuous records dating back 34,000 years, and possibly 41,000 years. Is this possible? Not only do I think it possible, but I think a number of factors conspired to allow this to happen. But first I should remind the reader that in Europe we see a similar continuity in the cave paintings -- a record, if you will, stretching across the western continent for an unbelievable 20,000 years where the imagery remained unchanged, and never a single sensible human form was added to the herds of animals. Only that which was at odds with the normal visible world was recorded. That, in effect, is the status of the Olmec, or pre-Olmec, records also.

If the climate had not turned bad in Southern Europe in about 10,900 BC, perhaps we would today have readings on the significance and meaning of the cave paintings, direct from the mouths of the grandchildren of the original painters, 400 generations later. But the visual record was abandoned as the artists migrated away.

I should also point out again the inviolable nature of these cave decorations. Chauvet cave was decorated about 31,000 years ago and entered again 4000 years later for an inspection tour, but left untouched. There are other examples of humans recognizing the work of other people and respecting the past efforts. Four thousand years is twice as long as all of our sensible recorded history.

The Olmecs (I'll term these people "Olmecs," even though they may have been an entirely different tribe) may have migrated after 10,900 BC, when the northern jungles of Brazil shriveled up with the advent of the shadow days of the Younger Dryas. Or it may have happened later. After 9000 BC climatic conditions improved again, but the jungle and the rains had moved hundreds of miles north. Sometime after 8000 BC maize was first cultivated. [\[note 5\]](#)

Unlike the caves of France, the Olmecs took their records with them, for they were portable, painted on skins or wood slats, and later recopied to folding bark books. The records not only

included the extensive sightings of the three-cornered stone, but also the disarticulated form of the Saturnian planets recorded in European archaeology in the Magdalenian period, and life in the cold of the shadows of the period after 10,900 BC, as retold in the *Popol Vuh*.

All of these records might have been discarded if it had not been for the later recognition that the first record of the world was an image of the maize kernel. The importance of maize to Central America, and eventually to all of the Americas, cannot be underestimated. Maize is the most productive cereal in the world; it is the easiest to alter genetically; it can be forced to grow under widely diverse conditions -- from the cold river valleys of Minnesota to the rain jungles of Guatemala to the high altitude deserts of the Andes.

Maize was life, and the first book of the Olmecs, as noted by the Quiche Maya in the *Popol Vuh*, was called "The Dawn of Life." It was about the maize kernel in the skies.

The other question, of course, is, were there humans 35,000 years ago in Central America, Venezuela, Columbia, Northern Brazil, or Peru? The conviction of US archaeologists is that the American continent could only have been invaded during the cold spell of 10,900 to 9,000 BC when Asiatics might have walked across the Bering Straits, even though there was no glaciation at this time to remove water from oceans, and Alaska was covered by tundra.

But the archaeology of Chile speaks to occupation by 35,000 years ago. North American archaeology has, in the last decade (2000 - 2010), come around to dates of 30,000 and 40,000 for Clovis and pre-Clovis sites. The period prior to the Clovis people, what is now known as the Paleoindian, has been identified with the European Mousterian tool tradition, which dates back some 300,000 years. This is enough time, certainly, to make it to the American Continent.

From Johanna Nichols we have more succinct data, based on grammars along the Pacific basin (requoted from the chapter "Language and Causality"):

"An enormous and sustained wave of human migration started about 50,000 years ago somewhere in Southeast Asia. Over thousands of years, successive bands of people spread out from the region. They could move relatively quickly because they were coastally adapted -- they knew how to make simple boats and make a living from the sea. Over thousands of years, some carried their languages south and west through coastal New Guinea and into Northern Australia, while others moved clockwise up the coast of Asia, across the Bering Strait into Alaska, then down the west coast of North and South America."

-- Bob Adler, scicom.ucsc.edu

There is no need for "simple boats," for these same people populated all the Pacific Islands (including Hawaii), and left their carved petroglyphs after 10,900 BC -- but were wiped off the islands by the flood of 3147 BC. The Americas could have been populated even long

before 50,000 BC. After all, Cro-Magnon types had reached western Australia by 65,000 BC, and may have reached South Africa 10,000 years earlier. By boat; always by boat.

In earlier text I suggested that in the long period preceding the (European) Gravettian period (28,000 years ago) Saturn might have regularized its orbit to equal some multiple of Earth years. It would be highly unlikely that records were kept and engravings made if Saturn had been a constant feature in the night or day skies.

Here are the last six of the seven stones, from Roy's translation:

"Thereupon he became man in the second infinite precious stone of grace. Then there arrived in the second Katun Alpilcon, as the angel was named when he was born. The second grace was permitted to depart in the second infinite night, when no one was present."

"Then he received his divinity, alone and through his own effort, when he came to depart. 'O firmar' he said, when he received his divinity by himself and through his own effort."

"Thereupon he departed and went to the third infinite precious stone of grace. Alba Congel was the name of its angel. This was the third grace."

"Let me proceed to the fourth infinite precious stone of grace, to the fourth night. Atea Ohe was the name of its angel. The fourth grace was born and began to speak, alone and through his own effort. 'Ohgod, the ruler! I am after all nothing in myself.' These were his words in his concealment, in his divinity within the grace."

"Let me still proceed,' he said. Then he went to the fifth infinite precious stone of grace, to the fifth infinite night. The fifth grace was born in the fifth Katun. Thereupon he was set up to declare his divinity. Then his angel was born; Decipto was the name of his angel when he was set up."

"Since it is so, let me go. Who might I be? I am a god, a ruler, after all,' and he declared his divinity all alone. 'A ninite dei sin,' he said when he received his divinity all by himself."

"Then he went to the sixth infinite precious stone of grace, to the sixth measured night, to the sixth Katun: 'Ye gods, ye rulers! Make answer to my words. After all, I am nothing in myself alone.'"

"The seventh grace was born. Conlamil was the name of his angel. 'I deliver the things of god to you who are gods. Answer my words. After all, there is no one; no one replies to my words.' Thus he spoke as he caused the seventh grace to be born. And there was joy in his heart at the birth of the seventh Katun, the seven lights, the seventh measured

night (and) the seven infinite (things)."

The "measured night" is generally rendered as "immensity of the night" by Bolio. Bolio also translates "Katun" as "warrior" for some poetic reason.

In Europe the series of far-off sightings of Saturn continued past 28,000 BC, when the Fat Lady first shows up in Europe. This would last (in Europe) through the Magdalenian period ending in about 14,000 BC when the figurines stretch to elongated amorphous shapes, the result of seeing the Saturnian planets from an equatorial level. Then much of this ceases in Europe, to be picked up again after 6000 or 4000 BC.

For the Mesoamerican record of the pre-Olmec people a more interesting continuous coincidental chronology can be found in the graph of a record of Carbon-14 differences in marine sediment near Iceland by A.H.L. Voelker (1998), which has become a standard reference, and which shows nine distinct peaks of Carbon-14 differences since 50,000 years before the present.

Except for a peak in 47,000 ya, nothing much happens until 41,000 ya when there is a sudden peak. This date of 41,000 bp is associated with the sudden demise of megafauna in Australia and Southeast Asia, and the appearance of radioactive isotopes above the normal background level. This was presented by Firestone and William Topping in "Terrestrial Evidence of a Nuclear Catastrophe in Paleoindian Times" (*Mammoth Trumpet Magazine*, 2001) and in the book *The Cycle of Cosmic Catastrophes* (2006) by Firestone, West, and Warwick-Smith. The last of the remaining series of eight peaks falls in 10,900 BC, the start of the shadow period of the Younger Dryas.

It is possible to misread both this data, as well as this well-intended but absolutely obscure section of the *Chilam Balam*, so that perhaps there is no relationship. This is pointed out by the fact that in the following paragraphs very little is said about the Younger Dryas. My confidence in seeing a connection stems from the fact that I have consistently been able to penetrate the arcana of the *Chilam Balam* on the basis of matching details against the model derived from the mythology of China, India, Mesopotamia, and Egypt. This is not the case here, but the match is against chronographical data.

The seventh stone might actually be the very last contact shown in the chart, in 12,900 bp (10,900 BC), which obliterated and burned down the North American landscape. If so, then the first instance of a contact with Saturn has to be dated to 38,000 bp. I can count seven "Carbon-14 events" to the start of the Younger Dryas if I include the Younger Dryas event itself. The cataclysm of 34,000 bp also matches the development of the diverse toolkit of Cro-Magnon in Europe and elsewhere -- suggesting the sudden cultural development of language.

In the next few paragraphs we will move from 38,000 bp to 12,900 bp (10,900 BC), the start of the Younger Dryas. What is missing from the text is the details of the shadow period of the

Younger Dryas after 10,900 BC, although this is certainly represented in the descriptions of the earlier seven stones (as being of an infinite night). We will, however, receive notice of the opossum ball plasmoid (after 10,900 BC), the plasma instabilities recorded as petroglyphs (10,900 BC to 8347 BC), the later swirling clouds (after 9000 BC), and the egg standing in the sky (before circa 4900 BC) -- all before the fire in the sky (4077 BC).

We are next given notice of the extensive passage of time, in some conglomerated form, notice of a long night, the rearrangement of other stones, and eventually the birth of God -- in essence the lighting up of Saturn. I should point out that, on the basis of much later claims, it is 10,900 BC, the first appearance of the Peratt column and the plasmoids which starts the "first creation" -- not the lighting up of Saturn in 4077 BC.

The endless night

A paragraph about an extended passage of time follows. It probably pertains to the extended time of the actions of the following paragraphs, or as likely makes the case for the previous text about the stones.

"Abiento bocayento de la zipil na de fente note. Sustina gracia, trece mili, uno cargo bende. The first, the second, the thirteenth unfolding; thirteen banners of the Katuns; three, seven, eight thousand."

The first line is fake Latin and Spanish. The second line delineates a rather large time period, which I will discuss further below, under the heading of "Notes on the large spans of time." Bolio has a similar translation, *"three times four hundred epochs, thousands of epochs."* This better catches the poetic expression (as a metaphor) for an immense period of time, and was probably meant to pertain to the period from 10,900 BC to 8347 BC, but is also (I suspect) applied retroactively to the appearances of the seven stones.

This is thus perhaps all that is said of what would be the time of shadows, 10,900 BC to 9000 BC. Note that the second book of the Quiche Maya was called "Our Place in the Shadows." The *Popol Vuh* spends an inordinate amount of time recalling the miseries of the 1500 years of the Younger Dryas -- the dark before the chaos. In fact, the authors of the *Popol Vuh* warn us that it will take considerable time to set out the details of this period of misery. It was not limited to the Quiche Maya, but involved all the other tribes.

Next comes the birth of God, although it will take time to arrange heaven and start creation -- toward the end of a long period. The long nights of 10,900 to 9,000 BC are mentioned again in passing over the course of the next four paragraphs (and as the "infinite nights" of the previous text).

God wakes up

"Then God the Father awoke to consciousness alone in person; in the three-cornered precious stone of grace he awoke to consciousness, God the Father, as his name was known to be. Unidad and God the Father, these were his names, cleft from the Katun for you."

"There were three generations suddenly augmented in stature when he came. Seven were the generations of his angels. Four times did he first speak. There was one seal in the darkness, one seal on high. 'I am the beginning and I shall be the end.'"

The "three generations ... augmented in stature" probably represent three ball plasmoids of the south.

The "seven generations of his angels" are probably the count of Saturn's readily visible satellites -- the same count as in Egypt, where they are called "the helpers of the King." This should not be so, since Earth was still within the swirling glow mode plasma of Saturn. Maybe this detail was added at a much later time. Or else this is a reference to the appearances of the seven stones.

I cannot easily place the "four times he spoke." This might be a reference to the seven stones. If so, it could be the damaging contacts with Saturn: 41,000 bp, 34,000 bp, 16,000 bp, and 13,000 bp, where 13,000 bp (12,900 bp, 10,900 BC) is the start of the Younger Dryas.

[\[note 6\]](#)

"Here are his words in their mighty entirety. 'Datate, here to that which has been received. I am Unidate, I am also Unitata, I am the Dove, I am Unitata Anuni. Unidad cometh.'"

"Nilu was the name of the night. This was the first speech of God; this was the first speech of the Father. Of cleansed stone was his precious stone alone in the night."

The night is mentioned three times, "in the darkness," "the name of the night," and "alone in the night," in addition to "Nilu." It is likely that these last few lines actually reference the shadow of the Younger Dryas (10,900 BC to 9,000 BC), along with the Peratt column (which is usually presented as speech). The rest are fake elements from the Latin liturgy.

The six winds

"Etomas, Cipancas was the name of the wind. Hun Katun was his father. Otahocanil Aucangel was the name of the wind. H(i)eron was the name of the Wind. Xicluto-tu-tanil was the name of the wind. Virtutus was the name of the wind. Joramis was the name of the wind in the second Katun. This was what he said when he changed the stone: 'Jaxyonlacalpa.' He covered the name of the holy heaven which our holy Lord, the Father raised up."

Here we have the mention of six winds. Roys writes, "Maya /ik/, here translated as wind, also means breath, life and spirit." If so, then I would suggest it could be the haze of the chaos surrounding Saturn -- a coma -- or could be beams of electrons, seen near Earth as six of the 28 which surrounded Earth. All other descriptions in antiquity reduce these to four visible streamers.

The Peratt Column, the opossum

At this point a serpent is introduced which initially seemed entirely out of place, since I first thought it to be Venus and its plasma tail connection to Saturn. But it is the tail of the opossum, the column extending from the far plasmoid, up toward the south polar region of the Earth (which, of course, looked like it extended up from the beast).

"Bolay [beast] was the name of the serpent of the second [other] heaven. He was in the dust at the feet of Sustinal Gracia [sustinal grace, Saturn in the north], as he was called. Then Lonmias was formed. The sharp stone was his stone within the night. Zihontun was his stone, when these stones were fixed in their places."

"Three times they were set at the foot of Sustinal Gracia [sustinal grace, Saturn]. These stones were born, they were beneath the one stone, the mighty pointed stone [Saturn], the stone column, the mighty pointed clashing stone. They were manifested [shown] all over the world (by) God the Father, the first ruler."

"Three times they were set" we know from other sources, including the *Popol Vuh*. Three times the ball plasmoids collapsed and reformed. I have described that earlier.

The "beast" is of course the Great White Opossum in the south, discussed in the chapter "The Peratt Column." The serpent is probably its tail, or there could be a translation glitch, since "serpent" and "sky" is the same word in Mayan.

"The mighty pointed clashing stone" is an interesting concept. It would suggest a changing plasma connection between the Saturnian planets, or a change in the point of view, since Earth was not directly below Saturn at first.

Although the Peratt column was well outside the Earth's atmosphere, electrical discharges above the stratosphere were perhaps "heard" within the atmosphere of Earth, as with exploding bolides today. The earlier mention of "four times did he first speak," could be accounted for then as the thunderous sound of the electron streams switching to arc mode.

The *Popol Vuh* assigns the first four fathers of the Quiche nation to these four electron beams. Amazing as this is, there is no question on this assignment in the *Popol Vuh*. The text reads:

"Perfectly they saw, perfectly they knew everything under the sky, whenever they

looked."

Bolio ends the first paragraph above with the following, perhaps skipping the references to Lonmias and Zihontun:

"There wisdom is formed, beating the stone inside the darkness."

"Beating the stone inside the darkness" might express the same idea as the clashing stone. On the other hand, it could refer to the three plasmoids seen in the south, and this would probably mean that the ball plasmoid would be seen rising daily in the sky, and then lowering again. They most likely appeared in the southeast and disappeared later in the southwest. "Inside the darkness," most likely recalls the time of the shadow of the Younger Dryas.

The following is Bolio's somewhat more lucid translation of the second paragraph:

"And the Archetypal Stone was created that founds the stones that followed, the three Stones that were to be seated at the feet of the Sustinal Grace. The stones that were born were beneath the First Stone. And they were equal sisters."

This at least clearly points to a count of three plasmoids. The "Survey of the World" (to be discussed separately below) calls them trees or bushes: "the white 'guaje', the 'ixculun' (and the gumbo-limbo (tree)." These lumps in the plasma column are noted as being "at the feet of" or "born beneath the First Stone."

The Olmecs knew where Saturn was, even though it might have been clouded in mists -- and perhaps for as much as 5000 years after 10,900 BC. "At the feet of the Sustinal Grace" (Roys has "in the dust at the feet") also implies that the plasma streams continued through the sky to the north and contacted the globe of Saturn. In arc mode this would certainly have been seen (although terminating at Mars and Mercury). This much is also strongly suggested by the existence of oval rings of standing stones at the northeast ends of some of the causeways at Carnac (in addition to the circles of stones at the southwestern ends).

The "three stones" are not what archaeologists identified as the "three hearth stones" in Orion which were thought to be referenced by the Maya in stelae. The "three stones" were placed in the skies at the start of the "first creation" in 10,900 BC.

The Peratt discontinuities

Then follows a totally opaque paragraph:

"In the first Katun was born the only son of God; in the second Katun, the Father. In the third Katun was Expleo-ucaan, as he was called, who chastised him named Chac Opilla ['great work,' from 'opera,' but Luxton reads "lightning" for opilla] when he set up the heavens. Enpileo-u-caan ['complete the sky' reads Edmonson] was his name. Expleo [a

name for the sky] was his name within the first noose of God. Hebones was the only son of God. (Like) a mirror he was borne astride on the shoulder of his father, on the stone of his father."

Bolio has a text considerably more lucid:

"Then entered Chac the giant, through the crevice of the Stone. Everyone then was a giant, in one lone town, those of all the lands. And God was the first king."

"In the First epoch, the only Son of God was created. In the Second epoch, the Word. In the Third epoch, Expleo [the name of the sky] was created."

"And Chac, the Giant, was born, whose name was Opilla [lightning], at the same time as his heaven, Empileo, was formed. Expleo [sky] is its name inside the first Book of God. Hebones. The only Son of God, mirror that will open his beauty, is the Lord of the Stone, Father."

At best I would assume this to be about various forms of plasma instabilities -- including a giant "squatting man" form. The text suggests that the plasma instabilities showed up at three different times. Since the periods are called "epochs" these would hardly consist of yearly intervals. Although Peratt has suggested that there were apparently three periods when the cliff-wall forms were carved, he also suggested that any instabilities of the plasma column would have lasted for decades.

The previous paragraph by Roys also noted that *"three times they [the stones] were set at the foot of Sustinal Gracia,"* although Bolio translates "three times" as "three stones." There are three main causeways of standing stones at Carnac also (geographically all in a line). This detail from Carnac could certainly indicate the number of appearances of the Peratt column.

The change of "noose of God" to the "book of God" is an interesting change in translation. I'm happier with "the book of God." I wonder if this was one of the sacred books of antiquity.

The nova event of Saturn of 4077 BC

The third book of the Quiche Maya was called "The Light that Came from Beside the Sea" (perhaps this is the "first Book of God" mentioned above). This book recalls the "nova event" of 4077 BC. To have Saturn appear "beside the sea" the Olmec observers would have been on the north coast of South America or the east coast of Central America. [\[note 7\]](#)

"Then, it is said, the boldness of the heaven on high was created. This was one grace, one stone; then fire was created, Tixitate was his name, the light of the heavens. Sustinal, they say, was the light from that which lighted the heaven. Acpa, it was, who made the Katun after the light originated in the heavens. Alpa-u-manga was his name after it ended."

Luxton reads "Alpa-u-manga" as "Alpha and Omega." This is typical of attempts to give this text a sort of Christian flavor, as if Christian priests had to be mollified.

Luxton also notes that in a translation by Edmonson "sustinal" is not used as a name, but with the remainder of the line. The text is translated as, "sustaining will be the lightning, the shining of heaven." I would agree with Edmonson's translation.

There is no question that this is a celestial light, and associated with the "one stone" seen in the sky. The composite image of Saturn would have been reduced to a single orb as Earth dropped further below the Saturnian planets. The exceptions are Venus and Uranus, both of which were offset from the stack of planets. I would suggest that Uranus showed at the right edge, somewhat below Saturn.

Venus would show to the left of Saturn, so that, if Saturn is understood as a large person in the sky, Venus, with its tail connected to Saturn, would be understood as his right arm, holding some object. This is the scepter of kings and chiefs, both in Mesoamerica and elsewhere in the world, the cudgel of Narmer, as well as the "strong right arm" of the "Ancient of Days" figure of the Kabbalah.

As I have suggested elsewhere, this particular imagery depends on the assumption that Saturn rotated at the same rate as Earth, so that it would seem to stand still, or nearly so.

Interestingly, the paragraph suggests that the light (assumed here to be the nova event and blazing of Saturn in 4077 BC) only lasted a Katun, 20 years, for it receives a different name after the Katun ends. The two lines are, "Acpa, it was, who made the Katun after the light originated in the heavens. Alpa-u-manga was his name after it ended."

The names, as elsewhere, are nonsense.

The creation of the rings

*(These are) the angels of the winds which were set up while he created the star, when the world was not yet lighted, when there was neither heaven nor earth:
the Red Pauahtun,
the White Pauahtun,
the Black Pauahtun,
the Yellow Pauahtun."*

Bolio has, "the angels, spirits of the winds, were raised while the stars were created." I would go with "star" as singular. This describes the star form of a glow mode plasma impinging on Mercury from Saturn. "Star" as plural does not happen until a thousand years later, when the southern stars show up.

There are footnotes on these directional Pauahtuns being the winds or the rain gods of the

four cardinal directions, cited even by Landa, but perhaps more significant is Roy's note:

"The word, Pauahtun, is difficult to translate. The last two syllables, Uah and Tun, suggest a stone or a pillar set up or erected; but they are evidently personages, and the writer is inclined to identify them with the 'angels' described by Landa in his account of the ceremonies preceding the New Year."

The suggestion of "pillars" by Roys equates the four Pauahtuns not with winds, but with the four supports of the heavens found also in Egyptian and Chinese mythology (and Landa too). From Egypt, quoting Budge:

"At a very early date the four pillars were identified with 'the four ancient khu's who dwell in the hair of Horus,' who are also said to be 'the four gods who stand by the pillar-sceptres of heaven.' These four gods are 'children of Horus,' and their names are Amset, Hapi, Tuamautef, and Qebhsennuf. They were supposed to preside over the four quarters of the world, and subsequently were acknowledged to be the gods of the cardinal points."

-- E. A. Budge in *The Book of the Dead* (1895)

"He," in Roy's translation ("while he created the star"), is perhaps God the Father, identified earlier. "He" sort of weaves in and out of this narrative, and the identity of "he" is not always certain. At times it seems as if "he" is the personification of the original book that these histories were being read from.

At any rate, "he" created the star. The star has been identified by the Saturnians of Thunderbolts.info as four or more streams of plasma, in columnar form from (what looked like) the equatorial region of Saturn, impinging on Mercury (identified by them as Venus), which occupied a position below Saturn and above Mars, with the streams changing to glow mode on approaching Mercury.

But there is a completely different reading for the four winds. The four "winds" or "angels of the winds" are color-coded in the manner of the later directional trees. I suspect it may just have meant to signify that these were colorful. I also would suggest that these represent the rings which would have exploded outward from Saturn's equatorial region. Despite the association with the directional colors, there is no indication that these "winds" are meant to be assigned to the cardinal directions in the sky, except, of course, as suggested in the paragraph above.

We could thus assume, that they may represent four equatorial rings of Saturn of differing colors. Later indications are that eventually there were three sets of clearly seen rings, as in the *I Ching* and many other sources, and as mostly true today.

Creation of the rings would take time, and would only happen after the surface of Saturn

lighted up, which is why it would be recorded in a separate paragraph (or set of sentences, since the *Chilam Balam* indicates no paragraphs).

What is astounding is that seemingly we have here a step-by-step description of the process of a gas-giant planet going nova, which fully matches our expectations as determined from the nature of plasma, and the reconstruction made by other researchers from Egyptian, Mesopotamian, and Vedic sources. No other people in the world recorded these events in books to be passed down for thousands of years.

The assembly of God's heaven

"Here was the first heaven where God the Father was set up, grasping in his hand his stone, grasping his 'cangel' [dragon], grasping his wheel on which are hung the four angels of the winds. Cerpinus was the name of him who, under Orele, measured the land."

God the father (Saturn, already established as on fire, "the light of heaven") here holds Uranus (his stone), Venus (the dragon), he sits on his rings (the wheel) or holds them, and is accompanied by four other prominent satellites (the four angels of the winds), and (below him) Mars (Cerpinus) "measured the land." This last was a single white streak (a plasma column in glow mode) extending from below Mars to Earth. The imagery of the main god (here God the Father), holding his tools, is duplicated for Oxlahun-ti-ku in the world history of Book 10 of the *Chilam Balam*.

The Palette of Narmer duplicates the above image (of God the Father) also, except that the appliances are held by Mars during one of its lowerings to Earth. Saturn, in the Palette of Narmer, has been reduced to the knob at the top of the crown of the pharaoh. This might have been Mercury, which would account for the fact that the rings are not shown at all.

I might be in error about who Cerpinus is. Luxton suggests that "Cerpinus" is the constellation Cerpinus (which I cannot locate, unless Serpens is meant), rather than Mars, and located below "Orele" which he suggests is the constellation Orion. The very bright star Canopus is located below Orion. This might have become a model of the earlier southern plasmoids and the lines drawn north "to measure the land."

If this line stands on its own, then it might be the single white column, noted as "the rope" in Book 10 of the *Chilam Balam*, which reads "then it was that fire descended, then the rope descended."

Following the establishment of God's heaven, Christian names for major planets are given.

"He set up the planets, Saturn, Jupiter, Mars, Venus, which he said were held in the grasp of the god in heaven when he created them. This was the name of the heaven,

cristalino. Here were the Angels."

It is disappointing to see these planets, which were the Gods of the Maya, assigned here to a Christian cosmology. At the actual time of this history, there was only Saturn in concert with Venus (Mercury) and Mars. Jupiter was still unrecognized as an actor in the creation drama, although recalled from earlier times. It seems likely, therefore, that the four large satellites of Saturn are meant here, rather than four planets.

"Corpinus was the name of him who held aloft on the palm of his hand the Blessed Father (or, the blessing of the Father) when there was neither heaven nor earth. Inpicco was his name when all the angels were asperged [sprinkled]. Baloyo was his name when (the water) was sprinkled [or, when the angels were scattered]. Seros was his name, Et sepeuas. Laus Deo."

Luxton: Corpinus is likely Scorpio; Seros might be Sirius.

Holding "the blessing of the Father" on "the palm of his hand" seems like a gesture which should be assigned to Venus, in that we can imagine Venus, appearing left of the apparition, looking like a hand held in blessing. Of course there is a problem in that the "hand" here is personified, and I am not sure if the upheld hand was also recognized as a blessing in Mesoamerica. But possibly the scribe here again applies Christian symbols to a reading of ancient texts. His references to sprinkling -- presumably with Holy Water -- is clearly a Christian sacramental form.

The four angels, as I noted earlier, are most likely the four largest satellites of Saturn. What the sprinkling otherwise represents, I do not know. At first I thought it might simply be the continuous radial lightning strokes between the rings. But Bolio has, "[Inpicco] scattered all the angels." Bolio's rendering is confusing, and does not seem to relate to any expected process except the obvious movement of the satellites of Saturn.

The lowering of Mars to Earth.

"Below were Chac Bolay Balam and the cacao called balamté [a species of cacao]. Esperas was the name of the sixth heaven; Isperas was the name of the seventh heaven."

Chac Bolay Balam translates as Giant Jaguar Beast. It is Mars, not only because Chac Bolay Balam is located below, meaning below the One Stone (or God), but primarily because of the row of cacao beans below. This is a feature of Mars which I have been unable to identify, yet it recurs in Maya iconography -- a head with a missing lower jaw and with protruding teeth. It may, visually, represent the lower edge of the jagged lower hemisphere of Mars. This suggests, correctly, that when Mars was lit by the Sun (the Sun was now in the sky), part of the lower hemisphere would disappear from view from the vantage point of Earth, because the Earth occupied a position lower than Mars with respect to the direction from which

sunlight came -- just as, during the day today, the part of the Moon which is in shadow is not seen.

Chac Bolay Balam is thus Bolon Dzacab, "Nine Generations," of Book 10, who has been identified by archaeologists as Mars, and who appeared to lower itself toward Earth 8 times between 4077 BC and 3147 BC. Having identified Mars as located below the One Stone, the text continues with the assertion that now the world was about to be created by God.

"Then the world was created by God the ruler in the seventh Katun, created in the darkness named Espiritu."

The "seventh Katun" raises my suspicions that the seventh stone gave us God the Father (instead of the 8th). Additional considerations are listed further below.

"St. Edendeus (and) St. Eluceo were the saints who witnessed the birth of him who was hidden within the stone, hidden within the night."

Roys comments on the word "stone," in the line above about St. Edendeus and St. Eluceo:

"Maya, 'u lamay Tun,' probably the planted seed corn. The definition of this phrase, 'the square stone,' symbolizing the twenty years of the Katun, has long been accepted. The word for squared, however, is 'amay,' not 'lamay,' which means sunk out of sight, hidden."

But "lamay" probably is correct. What is being described, as the creation of the world, is actually the lowering of Mars from Saturn -- the first of some eight approaches to Earth between 4077 BC and 3147 BC. Book 10 of the *Chilam Balam* describes the mass of maize mash left behind, from which humanity was created, according to the *Popol Vuh*. Thus certainly we have here the creation of humans -- but after the creation of the world.

We should also not forget that we have, in this manuscript, the efforts of 16th century AD scribes at interpreting a mostly graphic record dating back to remote antiquity. If the original scribes had failed to note that the world and humanity were already in existence in 4077 BC, then there was no way for the later readers of these records to assume anything other. Only after 4077 BC, when a cloud dome appears at the north horizon, anchored to Earth, do we have a record for the existence of Earth itself. This is no different from the cave decorations in Western Europe, where for 20,000 years not a single human figure was depicted -- from which it could be concluded that there were as yet no humans at that time.

I probably do not need to point out to the reader that St. Edendeus and St. Eluceo, who witnessed the descent of Mars -- described as the birth of God -- are probably the two satellites of Mars.

Now we also need to get back to the earlier comment by Roys, about the "square stone,"

which he thinks is a misspelling of "amay," meaning "squared," as "lamay," meaning "sunk out of sight." Knowing that we are seeing a description of Mars sinking toward Earth, it is obvious that "sunk out of sight" was indeed intended. The "sinking out of sight" will be repeated two paragraphs further down. I will get back to this below.

Interestingly, Bolio adds, "It is repeated," and "then it burned, during the night," to the line about St. Edendeus and St. Eluceo where Roys has, "hidden within the night." This is likely a series of the arc mode anode displays at the lower hemisphere of Mars, aimed at Earth, and clearly seen as Mars drew closer.

Next we have an incantation in the manner of a Christian prayer, composed, however, of nonsense words:

"These were the words said by him who was hidden within the stone, hidden within the night: 'Tronas Aleseyo de mundo de gracia. En apedia tejo çipi dia te en pieted gracia. Santo Esuleptun jam estum est gracia. Suplilis el timeo me firme abin finitis gracia, y metis absolutum ti metis de gracia. Abegintis gracia, Edendeo gracia, de fentis de gracia, fenoplis Tun gracia. Locom dar yme gracia, tretris u mis gracia. Noçi luçi de gracia, in pricio de gracia, trese mili uno de cargo, leonte.'"

Roys comments, "Little, if any, of this hocus-pocus is Maya, and it is the conjecture of the translator that its source was some itinerant Spanish fortune-teller or astrologer. The repetition of the word 'gracia' suggests an incantation to make the corn grow."

Bolio similarly has, "This corrupted Latin text appears to be some sort of incantation to favor the creation of corn."

The discussion on creation can now reach a recap and a conclusion, starting with another mention of the immense span of time which lapsed before creation. (To be discussed further below.) Notice that God the Father is soon forgotten. What comes forward, and what is claimed to have its genesis in heaven, is maize.

"One, two, thirteen, one division, thirteen 'bakam' of Katuns. Three, seven, eight thousand was the creation of the world, when he who was hidden within the stone, hidden within the night, was born, when there was neither heaven nor earth."

Bolio has, "before the land was to awaken," for "creation of the world," which clearly indicates that this is a restatement, not an additional long span of time.

"Then God the Father spoke alone, by his own efforts, in the darkness that clung like a thrice withered fruit (to the tree). This was the first word of God, when there was neither heaven nor earth, when he came out of the stone and fell into the second stone. Then it was that he declared his divinity."

Notice that God the Father moves to Earth via the second stone, Mars.

"Then resounded eight thousand Katuns at the word of the first stone of grace, the first ornamented [embroidered] stone of grace. It was the macaw that warmed it well behind the 'acantun.'"

"Who was born when our father descended?"

"Thou knowest. There was born the first macaw who cast the stones behind the 'acantun' [pedestal]."

The macaw is the assembly of Saturn, Uranus, Venus, and the rings of Saturn. This becomes clear with the second use of macaw, above. The Saturnian assembly is here no longer identified with God the Father, who has slipped into the "second stone" and visited Earth to deliver maize.

I do not think that "eight thousand Katuns" can be taken literally, for this would represent 160,000 years if this were a time span of Katuns. Even if they were meant to be Tuns, it would still be way too long -- 8000 years. I'll get back to this use of "8000" further below.

Roys notes, "acantun could be translated as a stone set up on a foundation." It could also be just the pedestal; Bolio has "mountains" for "acantun."

"Warmed it well" makes sense. It refers to a change of perspective (because Mars was closer to Earth) which allowed the lower hemisphere of Mars to be seen as "on fire" from anode arcs. If this was the case as Mars was approaching closer to Earth, it would have looked as if Mars was "warming" the acantun -- dome, mountain, or pedestal -- being just above (or near) the dome of steam at the north horizon.

Bolio has "And its word was a measurement of grace, a spark of grace, and it broke and pierced the back of the mountains."

I wonder if "a spark [of grace]" is verbally equivalent to the fires seen at the lower half of Mars. Piercing the back of the mountains, drilling holes in the back of mountains, or for that matter, throwing stones behind the pedestal or mounted stone (which has to be the vapor dome at the north horizon), may describe the disappearance of Mars from view (seen from 20 or 10 degrees latitude) when it reached the closest position to Earth.

Mars was headed for the Earth's north geographic pole as the nearest gravitational contact point. The plasma stream from Saturn, enclosing Mars, would have to bend as it neared Earth to land at the north magnetic pole. The holes pierced in the mountain, the cloud bank at the north horizon, are the shadowed fluted areas which would show up in the morning and evening light of the Sun, as I have pointed out in earlier texts.

The north magnetic pole and the water vapor dome most likely were located at this time at about Hudson Bay. This is the reason why the Olmec record contains much more detail of the close approaches of Mars than recollections from other locations on Earth. Other recollections only note that Mars became a giant at times. Mesoamerica is directly south of Hudson Bay.

"How was the grain of maize born? How, indeed, father?"

"Thou knowest. The tender green (shoot) was born in heaven."

The text continues with more nonsense:

"'Ciripacte, horca mundo. Ni mompan est noche. Amanena, omonena, apa opa,' (was said) when the wind emerged from the great stone of grace. 'Cipiones ted coruna, pater profecido,' were his words when he arrived at the seventh stratum of the solid rock of grace."

"'Bal te piones, ordeçipio, reçi quenta noche. Hun ebrietate, hun cute profeciado,' were the words of the Angel, Jerupiter. Then the sky was put in its place, 'Corporales ti ojales,' by the first pope, the face of the Katun, the burden of the Katun 13 Ahau."

Bolio has "High Priest" for "pope." Suzanne D. Fisher inserts "buttonholes" after Bolio's use of "Corporales ti ojales." The mention of Katun 13-Ahau is included with these lines by Roys. Bolio moves it to the beginning of the next paragraph, which makes more sense, since Katun 13-Ahau will signal the end of the creation event, followed directly by Katun 11-Ahau, which is always understood as the start of history.

The end of creation.

The translation by Roys has, as the next few lines:

"The face of the sun shall be turned from its course, it shall be turned face down during the reign of the perishable men, the perishable rulers. Five days the sun is eclipsed, and then shall be seen the torch of (Katun) 13 Ahau, a sign given by God that death shall come to the rulers of this land."

The "five days" is a reference to an event of the far future: the 685 BC nova event, when the Sun (our current Sun) in fact "turned from its course" and was occluded for five days by the arrival of the plasmoid from Jupiter. These events, as was well known, happened in Katun 3-Ahau which ends in 668 BC (6.4.0.0.0), not in Katun 13-Ahau.

All of this is then put in the service of prophecy of an end-of-creation scenario in the arrival of Katun 13-Ahau.

"Thus it shall come about that the first rulers are driven from their towns. Then Christianity (shall) have come here to the land."

"Thus it is that God, our Father, gives a sign when they shall come, because there is no agreement. The descendants (of the former rulers) are dishonored and brought to misery; we are christianized, while they treat us like animals. There is sorrow in the heart of God because of these "suckers" [a reference to the Spanish]."

Bolio starts with:

"This is the face of the Katun, the face of the Katun, of the Thirteen Ahau: the face of the Sun will be broken. It will fall, breaking up on the gods of now. Five days the sun will be bitten and [not] seen. This is the representation of the Thirteen Ahau."

Katun 13-Ahau (real or not) is selected in this narrative because it precedes Katun 11-Ahau. The appeal to Katun 13-Ahau is probably a literary device, based on the well-established supposition that all pre-history happens during a Katun 11-Ahau (which follows directly on Katun 13-Ahau). Book 10 places all the action of the end of the "first creation" in a Katun 11-Ahau.

What is more important to notice is that Katun 13-Ahau is here used predictively to signal the intrusion of Christianity. Roys gives recognition to this with the wording, "thus it shall come about... ." It is not certain, in fact, if this description of Katun 13-Ahau belongs with this text.

The following page (of the original manuscript) is written in a different hand, and reads:

"In the year Fifteen hundred and thirty-nine, 1539, to the east was the door of the House of Don Juan Montejo, to introduce Christianity here to the land of Yucalpeten, Yucatan."

[signed:] *"Chilam Balam, the prophet."*

Roys writes, about Don Juan Montejo, and the door facing east:

"Here as elsewhere Don Juan de Montejo is confused with his father, Don Francisco, the Spanish conqueror. The door of the old Montejo mansion in Merida faces north, not east, and it is the belief of the translator that this reference is not to the actual house of Montejo, but to the compartment, or so-called 'house,' of the Katun-wheel in which is pictured Katun 11 Ahau, the first Katun of the Spanish Conquest in which Montejo ruled the country."

Notes on the large spans of time

A number of times in this text, there are suggestions of enormous spans of time. These are, as it turns out, poetic constructs. We should be able to recognize these poetic (that is,

metaphorical) references to large spans of time, like "three times four hundred epochs, thousands of epochs," in the texts.

For the period of the seven triangular stones each line is augmented with phrases like, "in the second infinite night, when no one was present." We know (assuming there is a correspondence between the seven stones and the seven Carbon-14 peaks) that the intervals between appearances of the three-cornered stones spanned thousands of years, for if Saturn were a constant element in the skies, no record would have been made in the Americas, Europe, Asia, or Africa.

At the end of the series of the seven three-cornered stones is a phrase expressing an astounding time span, "*The first, the second, the thirteenth unfolding; thirteen banners of the Katuns; three, seven, eight thousand.*"

Assuming Roys's translation is accurate, the "*first, the second, the thirteenth unfolding*" seems like a literary lead-up to the statement "*the thirteenth unfolding; thirteen banners of the Katuns.*"

The "thirteenth unfolding" is of course the extent of the whole of the "second creation" (not the "first creation"), which would have been the 13 Baktuns from 8347 BC to 3147 BC. A complete rotation of the calendar is 13 Baktuns.

This is exactly what other records claim: that in 3147 BC, 13 Baktuns were completed. Although it is possible to dismiss the text as metaphorical for "large spans of time" we should keep in mind that the Maya were convinced that the previous creation (the "first creation"), which ended in 8347 BC, had lasted 13 Baktuns, or at least ended when the Baktun count reached 13.

The next phrase, "*three, seven, eight thousand,*" would seem to refer to the time before the "first creation," that is, the time of the seven stones. If taken together with the next line, "*then God the Father awoke to consciousness alone in person,*" it would certainly seem to point to the start of the "first creation" as a terminal event of a yet larger span of time.

Here we need to account for perhaps 20,000 years (to about 34,000 bp). If we add the "*three, seven, [and] eight thousand,*" and assume these to be Tuns (years) rather than Katuns, we have a time span of 18,000 years, which is not unreasonable. It takes the history of the "seven stones" back to about 30,500 bp (18,000 years before 12,900 bp, 10,900 BC), which is about the time when caves in Western Europe were first decorated.

The second use of multiple Katuns reads, "*One, two, thirteen, one division, thirteen 'bakam' of Katuns. Three, seven, eight thousand was the creation of the world, when he who was hidden within the stone, hidden within the night, was born.*" This is almost an exact restatement of the earlier phrase about the span of time before the start of the "first creation."

As I have mentioned earlier, the *Chilam Balam* has no punctuation, and no indication of where sentences and paragraphs start or end. Additionally, translators are hampered by the fact that without a structure of events such as proposed here, they were faced with a tale of utter nonsense. This shows in the divergence between the two translations, and in the fact that, even with the structure I have introduced, at most we have only hints at what is being told.

There is another solution, however. The repeated use of the phrase:

*"One, two, thirteen, one division,
thirteen 'bakam' of Katuns.
Three, seven, eight thousand
was the creation of the world,"*

... of Book 11 of the *Chilam Balam* can be explained as a metaphor for an exceedingly large measure of time, without reference to any specific count of years.

Additionally, it is almost certain that "Katuns" in the phrase "thirteen 'bakam' of Katuns" is in error. A 'bakam of Katuns' is, I suspect, a Baktun. That is the only way to make sense of the large numbers.

Looking at the methods of computation of the people of Mesoamerica it becomes clear that "One, two ... three, seven, eight thousand" is a statement about the content of the "400s" register, the third row of the Mesoamerican 3x3 calculation board. The third row represented values of 2000, 4000, and 8000. [\[note 8\]](#)

The value of 8000, the multiplier for the last space on the board, is thus representative of the highest value of any use in commerce or in the accumulation of years. The numbers "one, two ... three, seven" are the multipliers for the values represented on the 3x3 board, and signify the progressive filling of the spaces of a row -- a metonym for counting. This seems to be the idea behind "one, two, ... three, seven, eight thousand."

This becomes clear when the full quote from the "Chilam Balam" is expanded line by line:

*"One, two,
thirteen, one division,
thirteen 'bakam' of Katuns.
Three, seven,
eight thousand
was the creation of the world"*

As poetry this might be parsed differently, but what should be obvious is that "One, two" are the values filling the first (1 0 0) and the second (0 1 0) counting spaces -- while "three" and "seven" designate the additional binary values filling in the first and second (1 1 0) and the

first, second, and third (1 1 1) spaces. For the third row this ends in a multiplier value of 8000. I realize that this skips "four" (0 0 1), "five" (1 0 1), and "six" (0 1 1), but we are dealing with poetry here, not math.

Thus the four lines from Book 11 of the *Chilam Balam* signify a "filling out" of the counting spaces to what would be the largest accumulation of a number count most likely used by the Maya (assuming no trader would pack more than 8000 cacao beans).

On the other hand, the other phrase, "Thirteen 'bakam' of Katuns," represents thirteen measures of 400 years, a total of 5200 years, "one rotation" of the calendar -- the same calendar which recycled in 3147 BC.

That the Maya used poetry in the *Chilam Balam* is affirmed by Munro Edmonson, in "Some Postclassic Questions About The Classic Maya" (*Fifth Palenque Round Table*, 1978), where he writes:

"Did the Classic Maya use parallelistic couplets? It now seems well established that they did. ... Despite criticisms and refinements of my argument (1971) that all formal Maya discourse is in parallelistic couplets, I remain persuaded that the exceptions to this rule are rare enough that it has positive utility in working out the syntactic and orthographic problems of Colonial texts, and I suspect that the same may ultimately prove true of the Classic inscriptions as well. The form is almost the definition of native 'poetry' from the Rio Grande to Tierra del Fuego."

"Did the Classic Maya use couplet kennings? Couplet kennings or 'disfrazismos' are ubiquitous in Nahuatl poetry and in the supposedly prose texts of the Yucatecan Books [the Chilam Balam] as well."

"They are markedly rarer in the Popol Vuh, though they do occur. The device depends on the dialectic process of combining the elements of a dichotomy or other dyad to produce a third and esoteric meaning (e.g. rope and cord means war). I am inclined to think this particular form may have been introduced into Yucatan from Central Mexico and hence may not occur among the Classic Maya, but the evidence is insufficient for a strong supposition."

With respect to the *Popol Vuh*, Tedlock, in his notes on his translation (1996 edition), offers syntactical uses of "pairing of words or phrases that are partly the same and partly different." Tedlock points up the uses of dyads and couplets, used metonymically, and quatrains in a manner not entirely different from Anglo-Saxon alliterative poetry, and gives examples of each. He also gives instances where onomatopoeia is used. The lines from Book 11 quoted above would certainly qualify for the use of kenning, even if only available in a translation.

This clearly brings forward the use of "one, two ... three, seven, eight thousand" as a metaphor for something entirely different from the actual meaning of the words in use. In

that the phrase clearly fits the manipulation of the 3x3 calculation board of the Maya, the suggestion that it was meant to stand for an enormous span of time would seem to be correct.

"Eight thousand" is used once more to signify a very large time span used near the end of Book 11, *"Then resounded eight thousand Katuns at the word of the first stone of grace, the first ornamented stone of grace."*

(2) A SURVEY OF THE WORLD

This second item is actually the opening page of Book 1 of the *Chilam Balam*, titled by the translators Ralph L. Roys as "The Ritual of the Four World-Quarters," and by Antonio Mediz Bolio as "The Book of the Lineages." Roys sees the present page as standing alone, and starts the translation of the following page as Book 2, under the title of "The Rise of Hunac Ceel to Power," which describes the migration of the Itza into the Yucatan. Bolio takes the present page to be part of the Itza history.

The page deals with the time of the "Survey of the World" -- the appearance of the Peratt Column and the attempts made by people to grasp the meaning of the phenomena. As I suggested earlier, the details of the "survey of the world" extend back to 10,900 BC.

The visual effects of the Peratt Column was a series of brilliant lines of electrons, passing over the Earth from north to south, and stationary. The lines would follow the Earth's magnetic field lines, and thus the lines rotated as the Earth rotated. In effect three or four of the surrounding streams of electrons would be seen above any location on Earth.

Beyond the Rivers

Roys starts the translation with a note that apparently the previous page is missing. So he starts in mid-sentence, as follows:

"... the first man [idol] of the Canul family. The white 'guaje', the 'ixculun' (and) the 'gumbo-limbo' [three tree species] are his little hut, ... The logwood tree is the hut [lean-to] of Yaxum, the first of the men of the Cauich family."

"The lord of the people of the south is the first of the men of the Noh ["South"] family. Ix-Kan-tacay is the name of the first of the men of the Puch family. They guard nine rivers; they guard nine mountains."

"Nine mountains," Roys suggests, is from "Bolonppel-uitz," which is, he writes, "probably a place-name in the south." But Bolio has, "Nine rivers guarded them."

Rather than guessing at what much of these texts mean, I will just propose the historic narrative, and see how close the texts come descriptively to the narrative. Let me thus

propose that the three trees are the three ball plasmoids of the "great white opossum" in the far south. The logwood shelter is composed of the overlaid nearby lines of electrons closer at hand, in the south, where the streams of electrons contracted (pinched) before diverging to ride over the Earth. Peratt offers a convincing graphic of this, from the perspective of Peru at about 14 degrees south latitude which has all the looks of a lean-to. The nine rivers, I would propose, are the nine rings of the Absu which were seen from the Yucatan or other locations at 10 or 20 degrees latitude north of the equator which interfered with the clarity of the image of the plasmoids. South of the equator the plasmoids would be seen in much greater detail. The nine mountains I cannot place.

Bolio's translation, here rendered in English by Suzanne D. Fisher, is easier to read. Bolio reverses the subject and predicate of the sentence about the rivers. Bolio writes:

"The Lord of the South is the root of the lineage of the great Uc. Xkantacay is his name. And it is the stock of the lineage of Ah Puch. Nine rivers guarded them. Nine mountains guarded them."

As the reader knows, there are no titles in the original, nor is there any punctuation. Roys sees the present page as standing alone, and starts the translation of the following page as Book 2. Book 2 is a long piece, mostly coherent except for two interruptions which describe migrations of the Itza into the Yucatan in the 9th or 10th century AD (which may have been the Toltecs). Hunac Ceel is a 12th century Itza ruler. Bolio, on the other hand, takes the present page to be part of the Itza history, but separates out the last page of the history of the Itza as dealing with a different topic, the fall of the Absu in 2349 BC (described as item 3 below).

[Image: Nazca lines, aerial view and electron beams as seen from below. After Peratt,

2007. The view at 20 degrees north would certainly make this look like a lean-to.]

I am making note of the context here because the page of the *Chilam Balam* under consideration stands out in three distinct ways from the "history of the Itza." First of all, if this description is part of the history of the Itza, it starts out far too early -- some 6000 years before the Itza arrive in Maya territory.

Second, the origin of a people is here placed in the south, in fact, beyond the nine rivers. The Itza came from the west, from the Valley of Mexico (as did the Toltecs).

Third, as I will quote further below, the first major task was a survey of the land. This is a land of mountains, as in the Guatemalan Peten region. The flatland of the Northern Yucatan was not occupied by humans until quite late.

The Colored Bees

But first, before mention of the survey, there is an interruption in the text. It is a list of the directional colors and properties of the cardinal points -- east, north, west, and south, always in this order, and always assigned the colors red, white, black, and yellow, in order. In all cases in the *Chilam Balam* the directions and colors are assigned to four individual trees, except on this page, where the assignment is to "flints" and other assorted things. Two of the flints (red and white) are also associated with Bee Gods. From Roys:

"The red [east] flint stone is the stone of the red Mucencab [Bee God]. The red ceiba tree of abundance is his arbor which is set in the east. The red bullet-tree is their tree. The red zapote . . . The red-vine . . . Reddish are their yellow turkeys. Red toasted is their corn [maize]."

Bolio has something similar, except that he writes "sacred stone" for "stone" and where Roys has "is his arbor" Bolio translates "its Hidden Center." The other flints (white, black, yellow) use a similar text (see below).

"Mucencab" is a Bee God. Mucencab is only mentioned in the first two paragraphs, and not again in the following two paragraphs about black and yellow flints. We have no idea what this Bee God represents. In the 500 years since the beginning of the 16th century AD, not a single Maya informant has managed to say anything coherent about Bee Gods.

The other three "flint texts" read as follows:

"The white flint stone is their stone in the north. The white ceiba tree of abundance is the arbor of the white Mucencab [Bee God]. White-breasted are their turkeys. White Lima-beans are their Lima-beans. White corn is their corn."

"The black flint stone is their stone in the west. The black ceiba tree of abundance is their arbor. Black speckled corn is their corn. Black tipped camotes are their camotes. Black wild pigeons are their turkeys. Black /akab-chan/ is their green corn. Black beans are their beans. Black Lima-beans are their Lima-beans."

"The yellow flint stone is the stone of the south. The ceiba tree of abundance, the yellow ceiba tree of abundance, is their arbor. The yellow bullet-tree is their tree. (Colored like) the yellow bullet-tree are their camotes. (Colored like) the yellow bullet-tree are the wild pigeons which are their turkeys. Yellow green corn is their green corn. Yellow-backed are their beans."

[\[note 9\]](#)

I think the significance of this insertion of descriptions of the color-coded cardinal points is to delineate an inventory of the Earth. Considering all the other items inventoried for each of

the colored flints (trees, fruits, birds, corn, squash), these four paragraphs read more like geographic descriptions -- an inventory of the Earth. The colors of the cardinal directions were (probably) a late addition since 3100 BC, and were probably added to the source codexes as a helpful aid in identifying the directions. After the geography has been declared, the surveyor arrives.

The Survey

Roys writes:

"11 Ahau was the Katun when they carried (burdens) on their backs. Then the land-surveyor first came; this was Ah Ppizte [Measuring Man] who measured the leagues. Then there came the 'chacté' shrub for marking the leagues with their walking sticks."

"Then he came (to) Uac-hab-nal to pull the weeds along the leagues, when Mizcit Ahau came to sweep clean the leagues, when the land-surveyor came. These were long leagues that he measured."

Bolio has, not altogether different:

"With the 'Eleven Ahau Katun' appears the retinue of their servants."

"And Ah Ppisté [Measuring Man] began to come. This Ah Ppisté [Measuring Man] was the measure of the earth. And then came Chacté Abán, to prepare the measurings of land to be cultivated."

"And Uac Habnal came to mark the measurings with signs of the herb; while Miscit Ahau came to clean the marked out lands and Ah Ppipsul, the measurer, came, who measured wide areas."

Katun 11-Ahau is the name of a double-decade period which is understood by the Maya as starting all history, if all of history is always repeated every 13 Katuns. As a result, Katun 11-Ahau is also the complete period before history.

The names upon names should not worry the reader. Mesoamerican languages, like most American Indian languages are action oriented, not time based. If an action happens, it has to be attributed to an agent. Additionally, as Roys points out, frequently the names are puns.

I have made note of the sweepers who cleared the lines in the chapter "The Peratt Column." The sweepers will recur a few lines down as bees that swarm at Cozumel.

"These were long leagues that he measured" and "who measured wide areas" both show that the survey was no small project. I would suggest that we are looking at a recollection of the brilliant stripes in the sky. To the later scribes of the Olmecs, and other peoples who came

before the Maya, the recorded events suggested that the survey was done for humans, and possibly by humans, and was a necessary task before settlement of a land after a migration from the south, although I am only suggesting this by implication from the opening statement of this page, "the lord of the people of the south is the first of the men of the Noh family." It is thus not specifically said that anyone migrated. The *Popol Vuh*, however, will suggest a migration from the east.

The use of this information as the opening page of the *Chilam Balam* makes sense in its use at the beginning of the history of the later Itza migration. It localizes the information from remote antiquity to the time and conditions of AD 1000 in the Yucatan.

The *Popol Vuh* also has reference to a "*measuring, staking, and stretching the cord in the sky, [and] on the earth*" -- all accomplished before any creation activity at all is started.

The ending paragraph of Book 11, "The Ritual of the Angels" (above), also references the measuring of the land, although I think the wrong white stripe is referenced -- it equates the plasma stream in glow mode (from Saturn via Mars) with the four stripes seen earlier.

Next after the "survey" we have a division of the east, north, west, and south of the land of the Yucatan to well-known and established families. Bolio, for example, has:

"Then a spokesman was established at the head of the mat."

"Ix Noh Uc presides to the east. Ox Tocoymoo presides to the east. Ox Pauah Ek presides to the east. Ah Miz presides to the east."

Following the list of chiefs of the east, there are three more lines for the other cardinal directions. All of this is obviously an effort to make ancient history fit contemporary facts. The Yucatan, a flat dry region, was not populated until 1000 BC to 300 BC (there are also suggestions of 2500 BC).

Interestingly, the *Popol Vuh* takes the same stance to the first humans, not only associating the first creation of people to this particular time of antiquity (although the *Popol Vuh*, probably in error, claims this is a time before light returned to Earth), but listing the four overhead streaks of electrons as the first created humans -- four brothers named "Jaguar Quitze," "Jaguar Night," "Not Right Now," and "Dark Jaguar." There is no question that the authors of the *Popol Vuh* have equated these first four fathers with the streaks in the sky. See the later chapter "The Popol Vuh."

Cozumel

The text about the families is followed by "directionally colored" bees. Roys has:

"The red wild bees are in the east. A large red blossom is their cup. The red Plumeria is

their flower."

"The white wild bees are in the north. The white pachca is their flower. A large white blossom is their cup."

"The black wild bees are in the west. The black laurel flower is their flower. A large black blossom is their cup."

"The yellow wild bees are in the south. A large yellow blossom is their cup . . . is their flower."

These bees, as I mentioned earlier, are not the satellites of Saturn, tempting as it might be to simply assign them to the era of Saturn. They are distinguished from being satellites by their association with the cardinal directions. These bees are geographically distributed. Roys continues:

"Then they swarmed at Cecuzamil [Little Cozumel] in great numbers among the magueys [or "sweet things"] of the land, the calabash trees of the land, the ceiba trees of the land and the 'chulul' trees of the land."

Bolio has:

"When the multitude of the children of the bees multiplied itself, the small 'Cuzamil' was the flower of the honey; the mug of honey was the first apiary and the heart of the earth."

Let me at least point out that, as the bees were swarming, it could be presumed that they were seen to move south to Cozumel, or actually the plasmoids, here identified as the hive and as "the heart of the Earth." The "heart of the Earth" will be identified securely as the three plasmoids of the south in the *Popol Vuh* (in a following chapter).

So, to complete a sensible image, imagine that the bees travel overhead along the four electron beams -- like the brooms of the Ley Line sweepers, or Mizcit Ahau who "came to sweep clean the leagues," or "Measuring Man" Ah Ppizte who came to "pull the weeds along the leagues."

Fuzzy, furry, moving shapes traveled south along the visible streaks in the sky. The shapes diminished in size as they reached the region above the South Pole, and came to a halt (probably) at the first ball plasmoid. The ball plasmoids had sprung into existence in response to the isolating layer of carbon dust in the Earth's stratosphere. The ball plasmoids might have looked like a hive or a swarm of bees. As seen through the shimmering and moving Absu, it would look as if the individual "bees" of the swarm continued to be actively in motion.

Worldwide the interpretations differed considerably. There is a progression starting with the dead herd animals painted by Cro-Magnons on the walls and ceilings of caves in Southwestern Europe between 30,000 to 10,000 BC. From the herds of dead animals in Europe, the extended concept 5000 years later in Europe, as well as in Western Asia and Northeastern Africa, is of the travel of the dead to a final destination in the far south -- often interpreted as a set of islands floating in a sea.

In Mesoamerica we have the same imagery in the skies, but here it is understood as bees traveling south along the beams of electrons. In the next paragraph these bees are converted into arrows or armies of archers.

Roys continues with:

"Kin Pauahtun [Kan Pauahtun, the wind-god of the south] was their priest. He commanded the numerous army which guarded Ah Hulneb [the Archer] at Tantun in Cozumel, (also) Ah Yax-ac [first turtle], [a] chinab [a handspan measure], and Kinich Kakmo [fire macaw]."

Roys has "chinab" with a leading capital. Bolio has something very similar:

"Kin Pauah was the great priest, the one who governed the army of the warriors and was the guardian of Ah Hulneb [the archer], on the altar of 'Cuzamil'; and of Ah Yax Ac-chinab [dwarf] and of Kinich Kakmo; [the sun-eyed fire macaw]."

This paragraph is, of course, about the three ball plasmoids. I am not buying "dwarf" as a designation of the second plasmoid. Peratt, in an illustration based on a reconstruction from extensive data, has the second plasmoid larger than the first (nearer) plasmoid. But the order may not be as I would have assumed.

Here Cozumel, or Cuzamil, an island off the east coast of the Yucatan, is equated with the southern ball plasmoid as an island rising out of the sea of the Absu, similar to how the Sumerians held the island of Dilmun (Bahrein) in the Persian Gulf to be the city of the Gods. Malta had a similar status, as did Crete. All four islands developed a funeral business in antiquity.

The "wind-god of the south" might be any vaporous formation (plasma) extending from the ball plasmoids (when they existed) or more likely the streams of electrons.

And who is the archer? In a footnote about the Archer and Cozumel, Roys writes:

"Ah Hulneb, the Archer, was one of the principal deities of Cozumel which was a center of pilgrimage not only from every part of Yucatan but from Tabasco as well."

I am more inclined to equate the Archer with the first (near) plasmoid which was the source

of the lines of electrons shooting into the north sky. The arrows were likely dispatched from the south to the north. The sporadic interruption of the lines of electrons could make these look like arrows shooting north. It brings to mind the "crossed arrow" emblem of the North African goddess Neith, as well as the assembly of shield and spears known as the "War Stack" altar at Palenque.

Kinich Kakmo, the sun-eyed fire macaw, will be recognized as the name for the whole structure of Saturn as the body, its rings as its colorful feathers, and with Venus as the head. The problem here is that this text might simultaneously point to the earlier ball plasmoid after 10,900 BC and to Saturn after 4077 BC.

As listed above, the handspan might have been meant to represent the width of the third and largest plasmoid. A handspan subtends 2 or 3 degrees in the sky (a half degree per finger). At a distance of 425,000 miles (685,000 km) from earth, this would represent a very large object.

Of course there are a number of other instances in mythology where the southern ball plasmoids are referred to in the same breath that the northern Saturnian apparition is mentioned. The Japanese *Konjiki* starts with names for the three ball plasmoids (as "born first") followed immediately with the names of two entities "born next from a thing that sprouted up like unto a reed-shoot."

The Mesoamerican *Popol Vuh*, despite its extensive anthropomorphizing, does the same, that is, it recognizes the simultaneous existence of the southern and the northern forms. And last, the standing stones at Carnac reiterate the same concept of spheres existing at both ends of the causeways.

(3) THE THIRD CREATION

I have quoted a first portion of the following in "The Day of the Dead," under the topic of "The Ten Suns." I have noted that this text describes the event of 2349 BC. As the most impressive event of the past it is perhaps not unexpected to find this description also on a separate page. It follows directly on a history of the Itza, and both Bolio and Roys have taken it to be such, but it has nothing to do with the Itzas. The beginning and end of the page are missing. The text below is from Bolio. Roys has a reading of the original texts which is radically different. The difference, I think, is that an attempt is made by Roys to integrate the action of this page into the more mundane activities of the history of the Itzas of the previous pages. [\[note 10\]](#)

"Our gods have grown!" their priests said (those from the Sun). And then days of the year were introduced."

"Behold abundant suns come,' they said. And the hoofs of the animals burned and the

edge of the sea burned."

"This is the sea of bitterness!" they said."

"And the face of the sun was corroded, and its face became darkened and was put out."

"And then, above, they became frightened. 'It has burned up! Our god has died!' their priests said. "

"And they were beginning to think about making a picture of the figure of the sun, when the earth shook and they saw the moon."

The Calendar and the Moon

All of this I have addressed in an earlier chapter. The page obviously relates to the event of 2349 BC, with the references to the "growth" of the Sun (what was seen of the primary plasmoid in the east), the nine secondary plasmoids seen above Central America and later in East Asia (abundant suns), the introduction of a new calendar (but not the Haab), the disappearance of the Sun as the axis of the Earth tilted, the burning edge of the "sea" (the Absu), the radiant heat felt on Earth, and the first appearance of the Moon, following an Earth shock.

"And then came the Beetle gods, the dishonest ones, those who put sin among us, those who were the mud of the earth. ('It was Ix-Tziu-nene who introduced sin among us, the slaves of the land when he came.')"

The "Beetle Gods" must be equivalent to the "swarming of butterflies" mentioned in Book 10 of the *Chilam Balam* (also in reference to 2349 BC). This is probably portions of the dust of the Absu coalescing into larger entities and moving about or falling to Earth. Roys suggests that "Ix-Tziu-nene" is a woman ("Ix") of the "Tziu" family, but offers that on the basis that this page is a continuation of the history of the Itza of the previous page. He also notes that "nene" translates as "mirror."

This last makes it look more like a reference to the Moon, which is feminine among the Maya. Thus it might be suggested that we are here dealing with a celestial being (or apparition) and not with a lady of the Tziu family. Ix-Tziu-nene is probably the Moon. The Moon, in fact, has been the only Goddess ever to appear among the Maya (although other minor goddesses were added after the invasion). "Ix" (a feminine prefix) would thus be appropriate, despite the fact that the Moon is here referred to as "he." The "mirror" would also be appropriate.

The "sin," I need not point out again, is plasma in glow mode, or long distance lightning among the rings. Further below this is equated with arrows.

"When they came, the Katun was ending. 'The Cursed Katun' was that which was ordered. 'Speak carefully, thus are the gods of this land!'"

"When the time of the next Katun commenced, and the Katun in which the dishonest ones were brought ended, the multitude of their warriors was seen. And they began to kill them. And they erected gallows so they would die."

I'll address the "gallows" and the "warriors" further below.

The Question of Dates

The question of dates for the 2349 BC event remains unresolved. As I pointed out earlier, the Maya source for Book 10 moved the event to a Katun 9-Ahau for the sake of establishing that the day of the "third creation" had fallen on a "Day of Kan" which fell on an equivalent Gregorian date of July 26th. We would hope that the present page would clarify this, but it does not. Of some interest is the fact that these events seem to have happened near the end of a Katun -- if that can be read from the text. In standard chronology, the events of 2349 BC should have been experienced near the end of Katun 4-Ahau, 1.19.0.0.0 (using the accepted method of retrocalculation). But the next Katun which is listed (see below) is 11-Ahau, 2.2.0.0.0, which could only follow Katun 13-Ahau. This is 80 years after Katun 4-Ahau. The problem with the date of the 2349 BC event is addressed in the previous chapter on Book 10 of the *Chilam Balam*.

The "multitude of warriors" must be celestial, and represent some aspect of the falling Absu. The "killing" repeats the action of parallel legends in India, the Levant, and Egypt. Killing was assumed on the basis of the amount of "blood" seen in the sky.

The Gallows

The "gallows" is what Book 10 describes as the "timber planted at the crossroads" -- the plume of plasma suddenly developing at the South Pole of Earth and extending probably some 20,000 miles (30,000 km) into the part of the Earth's magnetosphere away from the Sun. The bend in this, which would be seen rotating nightly as the view of the sky changed because of the rotation of the Earth, would be enough to mark it as a gallows.

"And Ox-halal-chan began to shoot them with arrows. And the gods of the country began to be evoked. And their blood spilled and they were seized by the Lords of the Deer and then they were astonished and their war ended"

Note, first of all, that warfare in Mesoamerica did not use bows and arrows. Bows were only used by hunters (and in executions by the Toltecs). This reiterates the fact that we are looking at lightning across the remaining rings of the Absu. The same is noted in Chinese legend -- that the nine additional suns were shot down with arrows.

Roys translates Ox-halal-chan as "Chan of the three arrows." A description seems to continue a few sentences further below. More blood is spilled there. And notice that the "Lords of the Deer" are invoked here as agents, which could refer to my earlier suggestion that Uuc-yol-zip should be identified as the Moon.

"The Eleventh Ahau Katun is seated on his mat, sits on his throne. There his voice is raised, there his nobility manifests. The face of their god emits rays."

"Leaves come down from the sky, flowered arches come down from the sky. Celestial is their perfume. Music sounds, the tambourines announce the Eleventh Ahau. He enters at dusk and happily covers the sun with his canopy, the sun that there is in Sulim chan [wet serpent], the sun in Chikinputun [Chakanputun, Sabana-de-chiles]. Trees will be eaten, stones will be eaten, all sustenance will be lost within the Eleventh Ahau Katun."

This seems to continue the exploits of Ox-halal-chan, "Chan of the three arrows." The leaves and "flowered arches" coming down from the sky, plus the perfumed air (the smell of alcohol in the Eastern Mediterranean region), only suggest a continued disassembly of the rings of the Absu. Music sounding like tambourines seems like the constant crackle of particulate matter from the Absu falling into and exploding in the atmosphere or ionosphere. This, by the way, is the only mention of something akin to cometary showers, but of course it was only heard at latitudes close to the equator.

Covering the Sun, now traveling in the "wet serpent" of the remaining ring of the Absu, with a canopy of nightfall is an interesting notion. Before this time the night would always have been partially lighted by the Sun-lit Absu. After 2349 BC true darkness was first experienced. Since "he" enters at dusk, "he" is likely a planet. I would suggest Jupiter, but the text could be referring to the Moon.

The quotation ends, typically, with warnings of dire starvation conditions.

Endnotes

Note 1--

Estimates are that the cup and tail marks extend from remote times to about 20,000 years before the present. Thus the classical Venus figurines of the European Gravettian interrupt the series of cup and tail marks. Since the figurines reappear in the Magdalenian period, starting about 17,000 years ago (although they now look elongated and distorted), it could be suggested that for an extended period of time, perhaps something on the order of 10,000 years, Saturn's orbit took it away from periodically being close enough to Earth to have the Saturnian planets observed individually.

The text of the *Chilam Balam* does not clearly define two differing periods and two differing "looks" for Venus figurines or the Saturnian stack (in the Gravettian and the Magdalenian). It is thus possible that the Olmec record only starts at this intermediate period after the Gravettian.

Note 2--

The number "7" does have metaphorical meaning in signifying the filling up of a counting board register, as described later in the endnotes. But since "7" is here used by itself and is not presented as part of some compound poetic trope, I think it exactly represents seven occurrences.

[\[return to text\]](#)

Note 3--

The intervals found from the plot of fractional global radio-carbon since 50,000 bp, shown below, suggests 500- to 4000-year intervals between electrical contacts with Saturn.

From these a range of orbital parameters can be derived from Kepler's third law, $(T_1/T_2)^2 = (R_1/R_2)^3$, by setting T_1 equal to one year (for Earth) and setting R_1 equal to one AU (for Earth).

The formula then reduces to finding the cube root of the square of the period.

The "fraction" of the total orbital period is, as before, determined by $(2\pi \cdot 100 \text{ AU}^2) / (2\pi \cdot \{\text{radius}\} \cdot \text{AU})$. From this the time in the Solar System is estimated from $\{\text{fraction}\} \cdot \{\text{period}\}$. This is a very rough estimate. The actual time that Saturn would be seen by humans would only be a fraction of the "years within the Solar System" -- the time that Saturn spent closing in on the Sun.

Possible period period (years)	and orbital radius orbit radius (AU)	for Saturn in the fraction of period	Paleolithic years within Solar System
4000 years	252 AU	.1984	793 yrs
2000	160	.3125	625
1000	100	.5000	500
500	63	.7936	397

Of the values for a period listed above, 4000 year seems the most likely, if the time span is 41,000 BC to about 12,000 BC, which is 29,000 years. Dividing 29,000 by 7 results in a period of 4142 years.

[\[return to text\]](#)

Note 4--

Although the text might imply that Saturn appeared regularly, the graph of changes in the Carbon-14 level over the last 50,000 years holds otherwise.

[Image: Fractional global radio-carbon since 50,000 bp.
After Firestone; from A.H.L. Voelker(1998).]

The peaks of 41,000 bp (#1), 34,000 bp (#3), and 13,000 bp (#7, the last peak) produced not only Carbon-14 spikes, but also radioactive residue and magnetic anomalies. All the peaks of Carbon-14 spikes suggest interactions with Saturn. At 41,000 bp, the megafauna of Australia disappeared, and a magnetic anomaly was experienced (as pointed out in Chapter 9, "Events of the Younger Dryas"). At 13,000 bp (10,900 BC) the megafauna of North America disappeared, followed soon by similar losses everywhere else. I did not mark 12,900 BC (the last peak at 10,900 BC), for it was apparently not distinguished by the Olmecs. This last peak became the starting point for a telling of the darkness, which eventually resulted in creation. So this peak was not one of the series of seven failed attempts by God to come into being.

Since the peak previous to 41,000 bp is nearly 8,000 years earlier, the cataclysmic event of 41,000 bp may mark the start of record keeping. But 34,000 bp may be more meaningful. It represents one of the two largest cataclysms, but at an unknown location. And it is also followed soon (29,000 bp) with the first decorated caves in Southern France and Northern Spain. It also matches the dates of the start of the first lithic blade industry (the Châtelperronian), much more advanced than the 300,000-year-old Mousterian tool tradition of the Neanderthals and earliest Cro-Magnon. That is true in Southwestern Europe. A Mousterian lithic industry existed in the Americas also.

Note 5--

The dates of 8000 to 7000 BC for the first appearance of maize are from stratigraphic estimates made in the 1960s and 1970s. Carbon-14 dates for maize reach only to 3500 BC. Plant domestication worldwide first occurs independently in about 8000 BC in China (millet) and in Anatolia (wheat), where it is noted as "in development" as early as 9000 BC. But then, the Levant and Anatolia are better studied archaeologically than most other areas of the world.

Both the domestication of grains and the domestication of sheep and goats in the Levant might very well have been hedges against starvation during the dark and cold period of the Younger Dryas. But with the improved (if displaced) climate after 9000 BC, the lure of scavenging and hunting returned. Hunting is a lot less work than agriculture, and more fun if there is game. Sheep herding spread west into Greece, Italy, and Spain -- dry regions with little game. In Italy and Spain the cultivation of grains did not take hold until much later.

The domestication of a variety of plants probably took place during the Younger Dryas in Southeast Asia, West Africa, Ethiopia, the Andes, and the Amazon, but in none of these places is it clearly noted in the archaeological record until after 3100 BC, at which time agriculture might have been the only choice for a livelihood.

Note 6--

Of the seven stones, only for four is it actually remarked that they received their divinity. The first and second and the fourth and fifth.

[\[return to text\]](#)

Note 7--

The oldest Olmec archaeological site is along the Pacific coast. This suggests that the Olmecs abandoned the coast of the Caribbean after the flood of 3147 BC, and settled on the Pacific. The Pacific site of Monte Alto, a ceremonial center established circa 2000 BC, was abandoned by 1440 or earlier. The abandonment was likely the result of the Pacific ocean impact of 1492 BC, but may also have been a reaction to the worldwide climatic downturn. The next ceremonial center was established along the Caribbean again, at San Lorenzo, in 1367 BC. As if there was still a lingering apprehension of immense ocean tides, the San Lorenzo ceremonial center was located far from the ocean and high up on a manmade mound which would have taken massive efforts to construct.

Note 8--

Let me introduce the methods of computation used by Mesoamerica for counting and

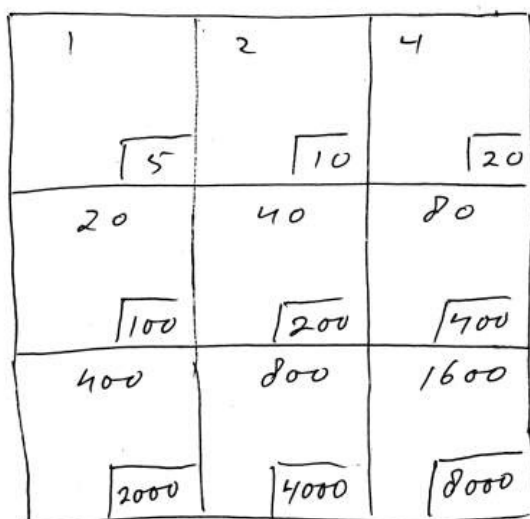

calculations. These are based on the binary manipulation of numbers in base-5 and base-20.

Nexus Tzacol (Reuben McDavid) of Project Ahau, originally at fortunecity.com/tattooine/replicant/29/, claims that, at the time of the Spanish invasion, a 3x3 checkerboard was in use by the Maya to do calculations. McDavid, however, gives no indication of its operation.

A 3x3 board certainly is a very small space. But it becomes believable when it is realized that the calculation in effect replicates the operation of an abacus, a calculating instrument based on base-5 and base-10. But unlike an abacus, the special rules for moving tokens from one square to another of the 3x3 board are very simple.

I will outline addition of base-5 and base-20 numbers on this 3x3 checkerboard, using only one or two markers per square. Subtraction would be similar.

Each row of the 3x3 board has to be augmented with a second space (perhaps as the lower part of any row), where the sums reached with calculations of the main space can accumulate. The main space of a row is thus used for calculations; the second space accumulates values which can be bumped to the next register (the next row of the 3x3 board) -- as needed.

1 5	2 10	4 20
20 100	40 200	80 400
400 2000	800 4000	1600 8000

[Image: Maya 3x3 counting board. Main area is used for addition, inset areas accumulate counts. Values for token positions are shown. Illustration by J. Cook.]

Let me now introduce the calculation area of the top row of the board. Here we are counting in units of 1, 2, 3, 4, and 5 -- except that on reaching 5 we will advance the count to the accumulation area of the same row, which will count 5's.

The spaces of the calculation area of the first row of the 3x3 board can have a count value,

left to right, of 1, 2, and 4. The tokens thus actually represent a binary count. I point this out because it will also hold for all greater values of numbers -- 5's, 20's, 100's, 400's, and 2000's.

The top level of the first row thus can represent 1, 2, 3 (which is 1 plus 2), and 4. I'll use parenthesis () for the tokens, square brackets [] for the multipliers, and curly brackets {} for the values. The placed tokens thus are, in order:

(1 0 0)	value of {1}
(0 1 0)	value of {2}
(1 1 0)	value of {3}
(0 0 1)	value of {4}
(1 0 1)	value of {5}

As a binary representation we could also represent the values of five (1 0 1), six (0 1 1), and 7 (1 1 1), but the values higher than five are of no interest in these calculations.

The rules for addition are simple: When any square holds two tokens, they are replaced by one token on the next square to the right -- which has double the value of the previous square. The operation is entirely similar to abacus usage: tokens can accumulate at a particular square, and be moved (carried to a higher value) when convenient.

The one additional rule to be invoked is that when five (1 0 1) is reached in the calculation space of a row, these tokens are removed, and one token is placed in the first square of the accumulation space of a row, which counts accumulated 5s. We could simply call this "the rule" or the (1 0 1) rule. It is marked (where applicable) below.

(1 0 1) becomes (0 0 0) - units (upper level)
(1 0 0) - fives (lower level)

The 5s register (the accumulation space of the top row) accumulates value in the same manner: anytime there are two tokens on a square, they are replaced by a single token in the next (right) square. The 5s register thus counts 1-five, 2-fives, and 4-fives. But it can also hold values of 5-fives, 6-fives, and 7-fives -- to be moved as convenient.

Recognize that the 4-fives count (the third square) has a value of 20, which is the next higher value in Maya enumeration.

There is no 1-0-1 rule for the accumulation space of a row. When a value of 20 is reached (4-fives -- which is one token in the third space) it can be moved to a next row of the 3x3 board, which will count 20's. So far we have:

Multipliers of each row:
row 1 calculation: [1 2 4] -- units, {1 2 4}
row 1 accumulation: [1 2 4] -- 5's, {5 10 20}
row 2 calculation: [1 2 4] -- 20's, {20 40 80}

Notice that the third line above, the 20's, which is the calculation space of the second row, will not progress in an orderly manner unless we again invoke the 1-0-1 rule. So, when five of the 20's (1 0 1) is reached, {20 0 80}, the tokens are removed and replaced with a token in the calculation register of the next row, which counts 100s. Now we have:

first row:
upper [1 2 4] -- {1 2 4} (rule)
lower [1 2 4] -- 5's, {5 10 20}
second row:
upper [1 2 4] -- 20's, {20 40 80} (rule)
lower [1 2 4] -- 100's, {100 200 400}

And adding the third set of counting squares:

third row:
upper [1 2 4] -- 400's, {400 800 1600} (rule)
lower [1 2 4] -- 2000's, {2000 4000 8000}

Am I on the right track? After developing this 3x3 addition method, I checked back with Nexus Tzacol's website, and ran into a quotation of Bishop Landa from *Relacion de las Cosas de Yucatan* (AD 1590), which reads:

"Their counting is 5 by 5 until 20 and 20 by 20 until 100, and 100 by 100 until 400, and 400 by 400 until 8,000, and this count was used for the cocoa trading. ... They count on the ground."

Georges Ifrah, in *The Universal History of Numbers* (2000), develops a very similar process using the dot and line notation in a column, where place notation is determined by vertical position. This is identical to the notation used universally among the stelae of the Maya. He notes that the assignment of powers of 20 (the base-20 place notation) was interrupted at the third level, where only 360 units were counted (18 times 20), rather than 400 units (20 times 20), and questions why this was so. Ifrah here confuses counting with the enumeration of the Long Count calendar. Ifrah points out that the fourth place in the place notation would thus have had a value of 20 times 360, or 7200 units. But Landa pointed out that the Maya counted to a value of 8000.

[\[return to text\]](#)

Note 9--

In a section of Book 10 which is clearly about Saturn, I identify the Bee Gods as the satellites of Saturn. It is little wonder that neither the authors of the *Chilam Balam* nor anyone else had managed to figure this out, for an enormous amount of time had passed, and the identity of the Bee Gods, who never did anything except buzz around the "hive," had been totally forgotten.

However, I do not think that the singular Bee God invoked here can be identified as a satellite of Saturn since only two Bee Gods are mentioned, one of which is in the north and may represent the terminal globe (Saturn) in the north. A bee in the east I simply cannot identify. It is possible that the south and west bees were simply forgotten in this enumeration, and that

additional bees should have been part of the directional inventory which is being listed here.

Note 10--

The translation by Roys is as follows:

. . . when our rulers increased in numbers, according to the words of their priest to them. Then they introduced the drought. That which came was a drought, according to their words, when the hoofs [of the animals] burned, when the seashore burned, a sea of misery.

So it was said on high, so it was said. Then the face of the sun was eaten; [4] then the face of the sun was darkened; then its face was extinguished.

They were terrified on high, when it burned at the word of their priest to them, when the word of our ruler was fulfilled at the word of their priest to them. Then began the idea of painting the exterior of the sun. [5] When they heard of that, they saw the moon.

Then came the rulers of the land. It was Ix-Tziu-nene [6] who introduced sin to us, the slaves of the land, [7] when he came. Then the law [8] of the Katun, the divination of the Katun shall be fulfilled. When he was brought, what was your command, you, the rulers of the land?

Then the law of another Katun was introduced, at the end of the Katun when Ix-Tziu-nene was brought. Whereupon a numerous army was seen, and they began to be killed. Then a thing of terror was constructed, a gallows for their death.

Now began the archery [9] of Ox-halal Chan. [10] Then the rulers of the land were called. Their blood flowed, and it was taken by the archers. [11] They were terrified . . . the time when the Katun ended for them . .

Roys's Footnotes:

- 4 -- "During lunar eclipses ... They say that the moon is dying, or that it is being bitten by a certain kind of ant (Aguilar 1921, p. 204). A similar belief was held of solar eclipses.
- 5 -- An alternative translation would be: "They began to imagine the reverse side of the sun."
- 6 -- Tziu is a family name, and /nen/ means mirror. Here it may be feminine.
- 7 -- /u mun nal cab/ might also mean: "the tender green corn of the land."
- 8 -- /Than/ has many meanings in Maya. The /than/ of the Katun is interpreted as "ordenansas" by the Kaua MS, p. 171 (Gates Reproduction).
- 9 -- Maya, /chulul/. This word has a number of meanings. In the Maya texts it usually

signifies either a bow or the chulul-tree from which bows were made (/Apoplanesia paniculata/ Presl.)

- 10 -- Literally, Chan of the three arrows. Chan is a common family name.
- 11 -- Maya, /ah-cehob/. The term implies hunters who use the bow and arrow rather than warriors. Ah Cehob could also mean the men of the Ceh family.

Calculations are in Unix bc notation, where ^ denotes exponentiation; the functions a(rctangent), s(ine), and c(osine) use radians; angle conversions to radians or degrees by the divisors rad=.0174 and deg=57.2958; other functions are shown as f(); tan()=s()/c()
units: million == 1,000,000; billion == 1,000,000,000;
AU == 93,000,000 miles.

Recovering the Lost World, A Saturnian Cosmology -- Jno Cook

Chapter 32: Olmec Site Alignments.

\$Revision: 42.104 \$ (olmec.php)

Contents of this chapter: [\[A Crisis of the Sun\]](#) [\[The Sun Returns\]](#) [\[Dates and Alignments\]](#) [\[Izapa\]](#) [\[Edzna\]](#) [\[Olmec sites\]](#) [\[San Lorenzo\]](#) [\[La Venta\]](#) [\[Other Sites\]](#) [\[Teotihuacan\]](#) [\[Monte Alban\]](#) [\[Divergent Alignments\]](#) [\[Summary of Alignments\]](#) [\[History\]](#) [\[Endnotes\]](#)

"The earth is round, like an orange."
-- José Arcadio Buendía, in Gabriel García
Márquez, *One Hundred Years of Solitude* (1967)

A crisis of the Sun in 685 BC

This continues the investigation into the Mesoamerican calendar started in a previous chapter. My main purpose originally was to check site alignments among early Olmec sites and locations in the Valley of Mexico. I wanted to see if the earlier inclination of the Earth's axis could be detected from solstitial alignments. But I soon realized that although there were many sunset alignments repeated from site to site, there were no solstitial alignments. What could be inferred from some of the later alignments which were found was the suggestion of a religious crisis experienced by the people of Mesoamerica in the 7th century BC. This is similar to what happened elsewhere in the world at the same time.

See Appendix C for specific data and calculations.

After writing most of the main text up to this point including Appendix A, "Notes on Chronology," and Appendix B, "The Celestial Mechanics," I started to look at the ceremonial centers used in antiquity by the Olmecs of Veracruz and the people of the Valley of Mexico. I wanted to verify the solstitial site alignments which Vincent H. Malmstrom, writing in *Cycles of the Sun, Mysteries of the Moon* (1979), had suggested existed for sites from Guatemala to Mexico. The thinking was, if some of these sites originated before 685 BC, then certainly there would be solstitial sunrise and sunset alignments at an angle of about 32 degrees north of the east-west cardinal direction, which would have been true if the Earth's axis were inclined at 30 degrees rather than 23.5 degrees. With the axis of the Earth aligned at 23.5 degrees to the normal of the orbital plane, this angle would be about 24 degrees. I looked at 15 sites, but found only one solstitial alignment -- in the current era. [\[note 1\]](#)

Malmstrom's book is a vast resource, but it contains errors in the promotion of a particular idea. Malmstrom's idea is that the 260-day calendar (called the Tzolkin) was first established at Izapa, where the Sun overpasses the site on August 13. It does not; I will discuss this further below.

Malmstrom thus points out "August 13" alignment at other sites, although most are for August 12, and many are confused with alignments for the date of April 19th. But August 12 alignments were certainly found.

But what I found in addition, were alignments to the setting (or rising) zenithal sun for six additional dates for almost all the sites, at some sites selected for the condition of a 30-degree axial inclination, at other sites for 23.5 degrees. Only two sites (**Cuicuilco** and **Tlapacoya**) mixed alignment under different axial conditions. All the site alignments pointed to giant mountains and the largest volcanoes in this region of Mexico, often hundreds of miles away.

I considered 11 volcanoes and large mountains. The exceptions were the use of an alignment defined by the major axis of the site itself (two locations for which I had data). After consideration of other sources from the Eastern Mediterranean, I was able to tie these dates to the catastrophic events of 3114 BC (August 12), 2349 BC (September 8), 1492 BC (April 19), 747 BC (February 28), and 685 BC (four dates).

The dates turn out to represent the end of the "Era of the Gods" in 3114 BC (a retrocalculated date, the actual is 3147 BC), the removal of the Absu in 2349 BC and the so-called flood of Noah as the culmination of the Pleiades three days later, the Earth shocks of 1492 BC and of 747 BC, plus a distribution of 4 dates which can be assigned to the plasmoid from Jupiter in 685 BC.

The initiation and arrival of the plasmoid (in 685 BC) represents a series of events which seemed to have caused some confusion among the people of Central Mexico. There is little agreement on *which date* or which event constituted the end of the era in 685 BC. The four dates are used in a nearly equal measure. It might also be suggested, consonant with the philosophy of Mesoamerica, that an era did not end at all in 685 BC.

Considering that there are 365 days in the calendar year, and that the Sun rises and sets at the same horizon locations twice each year, there are still some 182 days, and 182 locations along the horizon, which could have been selected. To have alignments consistently show up mostly on 4 dates only (plus three for 685 BC), is not a random distribution. Alignments for matching calendar dates vary at most by only 1/3rd of a degree between calculated and observed values from site to site. Thus, for almost all of the ceremonial sites, only 4 horizon locations were selected from among 182 possibilities.

It is also clear that almost all sites picked either to align their important "era-ending dates" to an axial inclination of 30 degrees or an axial inclination of 23.5 degrees. Only a few sites mixed alignment for different axial conditions as convenient to the mountains or volcanoes

which could be used. At **La Venta**, which was in use by 685 BC, we see the effort to change the major mountain alignment corresponding to a sunset for February 28 for an axial inclination of 30 degrees, to a new value for an axial inclination of 23.5 degrees by rebuilding the site with its axis aligned 8 degrees west of north. The perpendicular to the new site axis points to the new sunset location for February 28, 747 BC.

Additionally, all the Olmec ceremonial centers built after 1400 and 1200 BC were oriented so that the Sun would travel directly over the site and then set at a prominent mountain twice per year. These alignments were selected as a signature for the site location: having the sun set in a volcano on the day it would pass directly overhead at the site, or signaling some important event of the past, like the date (actually, the horizon location) of the end of a previous era. Both of these are obvious from an inspection of alignments between the sites and mountains for all the Mesoamerican ceremonial centers which I looked at.

I originally looked for solstitial alignments based on the work of Vincent H. Malmstrom, who, in *Cycles of the Sun, Mysteries of the Moon* (1997), had set out to demonstrate solar alignments of ceremonial centers of Central Mexico. The data collected by Malmstrom was meant to show both solstice alignments and "August 13" alignments (where the Sun set on August 13th).

First, let me present some comments about the apparent need for these orientations, as suggested by Malmstrom. He suggests, curiously, that the alignments arose from a need to "calibrate the calendar."

I don't think so. It is just unlikely that giant structures needed to be built to demonstrate over and over again where along the horizon the Sun set in mid-summer. The calendar didn't need calibrating; the Tzolkin calendar just continued to toll off days, one after another, as it had for thousands of years. Two sticks in the ground would demonstrate where the Sun set at the solstice. Additionally, the location along the horizon where the sun set at the solstice of summer (or winter) is the most difficult to pinpoint among all the possible locations where the sun might set throughout the year.

What I think should be inferred instead from the sunset and sunrise alignments is that the people of Mesoamerica were attempting to control the Sun's proper course, perhaps since the earliest times, but especially after 1492 BC when it looked like the world had come to an end, causing many long years of a deeply overcast sky, and the length of the year had changed. When the overcast skies cleared, 20 years after 1492 BC, it was noted that, for various critical days in the year, the Sun again set on the proper days of the Tzolkin calendar -- as if the Tzolkin had regulated the sunsets -- even though the solstice sunset had relocated and the year had lengthened. No one paid attention to the location of the solstice sunset or the length of the year.

We have to realize that the ceremonial centers of Mesoamerica -- all the sculptures and murals, all the stelae and dedicatory objects -- deal almost exclusively with religion and

nothing else. To invoke kings for the Olmecs, or conquests for **Teotihuacan** cannot be adequately supported. Certainly we see armed men among the depictions, and later tribes actively attempting to control other people by force, but the concepts of kingly leaders are late concepts among the Maya and Aztecs. The leaders were priests who were a privileged elite. The emperor of the Aztecs was known as the "speaker" -- he talked to the Gods on behalf of the people. **Teotihuacan** never had a standing army. The Classical Era Maya had neither standing armies nor a police force.

The armed men, and the wars among the Maya, were used to capture sacrificial victims, for blood was needed to maintain control of the Gods and to sustain creation. Armed men were also used, no doubt, to protect trade expeditions. Trade, initially used to support the priestly elite and the ceremonial centers, was extensive and would soon have supported independent traders as a class. Of course what we know of trade are only the objects which did not degrade with time -- ceramics and stone. But what obviously fostered trade was the enormous surpluses of agricultural products, the same economic force which supported the ceremonial centers.

It is thus also likely that the alignments were used to pinpoint the start of an agricultural year -- a New Year celebration -- against the rotating calendars. This can be seen in the activities at the Maya center of **Edzna** where the celebration of New Year was determined for all of the Maya centers of the Yucatan, by selecting the zenithal passage of the Sun as the significant date. More on this below.

A New Year's Day in late summer, anywhere in the region, would divide the agricultural year into the two planting seasons, the maize crop planted in spring was harvested in early summer, and the crop planted in late summer was harvested in fall. The overhead (zenithal) passage of the Sun would happen in early spring, and again in late summer at all locations in the region.

What was much more important was to control the path of the Sun, as a sign that the current creation of the world was being maintained by the shamans, by the continued use of the Tzolkin calendar, and by the use of the proper location of ceremonial centers. In a fashion typical of well-documented later Mesoamerican philosophical thinking, mankind was responsible for this, and the ceremonial sites implemented the control over the current creation. This is so entirely different from the attitudes toward the Gods which developed in the Mediterranean region, as to be nearly incomprehensible to Westerners.

It should be realized that the Sun was never a God in Mesoamerica, despite what archaeologists and anthropologists might otherwise suggest. References to a Sun-God will inevitably be references to Jupiter, the Midnight Sun. The Sun did not move irregularly; the planetary Gods did. The Sun always looked the same; the planetary Gods trailed feathers, as Venus did, or donned a tri-lobed headdress and took a body shape of an opened crocodile jaw, as Jupiter did, cruised close to Earth in an attempt to destroy creation, as Mars did, or brought flowers to Earth, as Mercury did -- all experienced as late as the 8th and 7th century

BC. The Sun was just an object, a part of nature like the wind and the rain, although created by the Gods. The only extant "creation myth" that has come down to us, the *Popol Vuh*, is clear about this.

Control of the Sun was achieved by anchoring its setting (or rising) at some date to a landmark mountain or volcano, sighted from a central point at a ceremonial center or a mountain-like structure at the ceremonial center. It gave the ceremonial center power over the Sun, and the Sun in reciprocity bestowed benefits to the ceremonial center. The benefits, of course, were prosperity, rain in season, large crop yields, and many children. What else would people ever want? ("Bishop Landa says that the aim and object of all Maya ceremonies were to secure three things only: Health, life, and sustenance; modest enough requests to ask of any faith." -- Morley)

I suggest, therefore, that the people of Mesoamerica had developed a strong interest in controlling the stability of the current creation -- at least since 1440 BC, if not earlier -- as expressed in the sunset alignments of the ceremonial centers. Building huge structures and siting ceremonial centers to alignments with distant mountains makes little sense if this effort was meant for keeping time or adjusting calendars. To understand the ceremonial centers as a means of controlling the path of the Sun, and additionally reaping agricultural and social benefits, makes much more sense, even though it looks like insane magic to us. I can think of no other reason why pyramids and platforms had to be built over and over again at every location where people concentrated in Mesoamerica. There are thousands of pyramids. When the Sun changed its path in the 7th century BC, the return to stability proved the efficacy of the Tzolkin calendar as well as the ceremonial centers. [\[note 2\]](#)

Sighting the rising or setting of the Sun along the horizon is a topological solution to tracking and controlling the doings of the Sun. The Olmecs were certainly correct to pick this solution after 1440 BC, and were vindicated in 747 BC when the Earth's axis again spun through a circle, and the length of the year changed, and again after another Earth shock in 686 BC and a passing plasmoid in 685 BC. After each of these disturbances the Sun quickly returned to its correct setting location -- but of course not on the same date of an equivalent Gregorian calendar. But the calendar date did not matter. It was the sunset location that was important.

[Image: Legend used for alignments. Plan view.]

With this the shamans of the Olmecs would repeatedly demonstrate that they indeed did have control over the Sun, for the location of the sunset of an overhead (zenithal) passage of the Sun remained virtually the same even when the orbit of the Earth changed and the year changed (as in 1492 BC and 747 BC), or the seasons fell into disorder (as after 685 BC) -- or, at least, so they claimed. A number of claims of the efficacy of the Tzolkin calendar show up in Book 10 of the *Chilam Balam*, which I have pointed out earlier.

The Changes after 685 BC

But then, unlike the changes which had happened in 1492 BC and 747 BC, something different happened. In 685 BC Venus attacked the Sun, chased away the stars at the North Pole, and dislocated all the other stars. But the Sun, after its overhead passage at any of the ceremonial sites, again set at the correct location of the horizon in the following year as in the previous times. The Sun definitely had left its path in the sky, but it was corrected, as the *Chilam Balam* reads, "*within the time of Katun 3-Ahau.*"

Well, not quite. The inclination of the Earth's axis had changed in 685 BC. [\[note 3\]](#)

The following were the changes over a period of 60 years or more, from 747 BC to sometime after 685 BC.

- **First**, the year lengthened in 747 BC. This happened, as we know from Babylonian records and the Olmec Long Count, on February 28th, 747 BC (February 26th after nightfall for Babylon, February 28th from the Roman calendar). The inclination of the Earth's polar axis remained at 30 degrees to the normal of the orbit at this time.

The Olmecs selected the date of the change to a longer year (the completion of the previous era), as February 28, Gregorian, as a New Year celebration. This remained in use in

Guatemala to today and was in use among the Aztecs.

The later change in the axial angle in 685 BC caused some sites to simply change the alignment of the site axis, as at **La Venta**. **La Venta** was initially aligned to a mountain located 11 degrees west of north -- by the choice of its location -- which celebrated February 28 while the Earth's axial alignment was still at 30 degrees. After 685 BC **La Venta** was rebuilt to have its long axis at 8 degrees west of north, thus aligning the site at a right angle to the new horizon sunset location for February 28th. Many later ceremonial centers (after 600 BC) followed this practice of a right angle alignment to an important sunset or sunrise.

The dates of the equinoxes and solstices would change with our calendar methods, but a change in the length of the year would not change the horizon location of sunrise and sunset at the equinox -- directly at the east and west cardinal points. Other sunset locations falling within a few months of the equinox changed, but often only imperceptibly -- a small fraction of a degree. It is the location of the solstice sunrise and sunset which would have changed radically. However, solstice alignments were apparently never used, and never recorded.

- **Second**, when in 685 BC Venus and Mercury blazed like suns, the inclination of the rotational axis of the Earth started to change. The actual date that Venus and Mercury started to blaze is June 15th (Gregorian).
- **Third**, the nova condition of Venus and Mercury was brought to a halt by a plasmoid bolt from Jupiter in late summer, arriving at the Sun on July 25th, Gregorian. This date is clear from the actual time interval mentioned in the *Chilam Balam* and from many site alignments which celebrate July 26 as New Year's Day.

The *Chilam Balam* claims that the Sun went off its path, that is, it did not set at the expected horizon location, for 40 days after June 15th. This was due to the ongoing change in the inclination of the Earth's rotational axis during that time period. Forty days after June 15th is July 25th.

Jupiter had started to brighten or blaze, like Venus and Mercury had done, but at a later date, apparently on July 9th. The massive plasma output by the Sun would have taken about 5 to 10 days to reach Jupiter. Because of its huge size, Jupiter did not form a visible coma (and other features) for some time. A switch from dark mode to glow mode would have been sudden, and would have been noticed. This happened on July 9th.

On July 14th Jupiter released a return lightning bolt at the Sun. This was seen and recorded worldwide.

The changes in 685 BC were the cause of extensive confusion. The problem would be immaterial from our perspective, but was of the greatest theological concern to Mesoamerica. The exact date that the previous creation had ended needed to be determined. The possibilities included July 9th, when Jupiter first erupted, understood as rising from death,

July 14th, when a plasmoid was released from Jupiter, understood as a decision by Jupiter to stop Mars from further interference with Earth, and July 25th, when the initial plasmoid landed at the Sun (although assumed to have been destined for Mars), which was seen as an extension of the current creation -- rather than an end of one creation and the start of a new creation.

It is obvious that a variety of new theologies would arise from these events. They include the resurrection of the Sun God, Jupiter, as had happened once before, in 2349 BC. There is also the concept of the self-sacrifice by a deity (Venus or Mercury) in order to save the world from destruction. The varied interpretations are found in the extensive information from Maya archaeology and documents like the *Chilam Balam*, the *Popol Vuh*, and many early retellings and reports by the missionaries. The initial and most visible physical response involved the realignment of some sites to new horizon locations and the use of these alignments for new sites.

- A few sites were aligned or realigned to July 9th. This is likely the day Jupiter first assumed a large coma again in response to the continuous coronal mass ejections from the Sun.
- A few sites use the date of July 14th, the day when Jupiter released a plasmoid lightning bolt in the direction of the Sun. This date can be derived from the *Chilam Balam*.
- Most sites accepted July 25th, the day the plasmoid landed at the Sun, for this certainly stopped the blazing of Venus and Mercury, and in effect closed an era.

The events were commemorated in a number of ways by the Olmecs and the people of the Valley of Mexico. The Olmecs, as well as the Maya (who had adopted the Olmec theology by AD 100), celebrated a New Year's Day on July 26th, Gregorian (the day after July 25th). In the case of both the city of **Teotihuacan** and Maya **Edzna** the locations of the ceremonial center were selected to coincide with the zenithal passage of the Sun over the site for the equivalent horizon location of the Gregorian date of July 25th. The zenithal passage of the Sun over a site on July 25th would only happen at a latitude of 19.5 degrees north.

[Image: Zenithal path of the Sun. Plan view.]

Vincent Malmstrom suggested in 1979 that a computational method could be used to find the day of creation (August 13) by counting 52 days into the future from the summer solstice. After 685 BC the solstice occurred on June 21. Fifty-two days later is August 12. This is based on the apparent numerological importance of the value of "52" in Mesoamerica, and despite the fact that the solstice is very difficult to determine. It would, thinks he, be a reason to note the solstice. But counting 40 days (two Uinal months) backward from the fall equinox of September 21 would achieve the same results, and be much more accurate. And then again, if you have a calendar, who needs to count days?

At any rate, Malmstrom is correct in suggesting that August 13th (actually August 12th) was one of the standard alignments used by many new sites. However, I think the date of August 12 represents a retrocalculated date for the event of 3147 BC (completion of the "first creation"), retrocalculated to 3114 BC by the Olmecs of **La Venta** after 747 BC, using the Long Count.

[Image: Plasmoid interplanetary lightning bolt.]

As will be seen from some of the alignments, many sites opted to duplicating the dates and horizon locations of previous eras at times correct to the axial alignment of the Earth during the previous eras, at other times translated to the proper horizon locations of the current era.

- **Fourth**, after 685 BC, the inclination of the Earth's polar axis changed from 30 degrees to the normal of the orbit to 23.5 degrees.

The *Chilam Balam* reads, "After three heaps of years it [the Sun] will come back into place in *Katun 3-Ahau*." The "three heaps" of years are three "bundles" of 5, thus 15 years, but counted inclusively -- thus actually 14 years. The "14 years" are 14 Tzolkin cycles of 260 days (about ten solar years), not years of 365.24 days. This is correct, that is, after 14 Tzolkin cycles the Sun set again at the same horizon location as earlier, although on a different date on our calendar.

The 16th century AD texts of the *Chilam Balam* go to prove that the Sun had returned, and are based on the knowledge that an inspection of records (which were at that time 1300 years old), showed the amazing coincidence that, for a zenithal passage of the Sun, 14 Tzolkin cycles would lapse after 685 BC before the Sun would again set at the same horizon location on the same Tzolkin day-name and day-number as in the year before 685 BC. This can be readily verified as true; I have done so in the chapter "The Chilam Balam Books." [\[note 4\]](#)

This is the clearest indication that there was a change in the axial inclination of the Earth. If there had been no change, it would have taken 20 Tzolkin years to return to the same Tzolkin day name and number instead of 14.

But under any conditions it would have taken some years for a number of diverse opinions to develop on what the changes meant, and how they should be represented. We start to see changes in alignments in the Central Mesoamerican region by about 600 BC. The Maya, on the fringe of this region, seem to have accepted a number of interpretations, including the celebration of New Year on July 26 (adopted from **Teotihuacan** in Mexico), and a new sunset for August 12.

The Sun Returns

How did the Sun find its way back to a proper alignment after 685 BC? It did not, at least, not in our way of understanding this.

What happened over the course of the 40 days is that, along with the change in the inclination of the Earth's axis, the horizon locations of the summer and winter solstices moved from about 32 degrees north and south of east and west to about 25 degrees north and south of east and west. But the seasonal calendar day of the solstices (and the equinoxes) also moved. They moved, in all, by 15 days. During other parts of the year, the locations where the Sun set for particular calendar days also changed. If any of these sunsets corresponded to significant calendar days before 685 BC, they were now incorrect.

But for a people who considered the year as consisting of a series of sunsets at differing horizon locations, the calendar days did not really matter. For one, the Sun would set at the

same horizon location -- before and after 685 BC -- on the equinoxes. Another demonstration of stability was that the horizon location of the day of a zenithal passage of the Sun over a site remained almost the same, even though the expected day on the Tzolkin calendar changed (as well as the day of the seasonal calendar). For all the sites at these latitudes, the angle of an alignment of zenithal sunsets occurred again, after the axial change, at within 0.3 degrees of the old alignment. The zenithal sunset locations were least affected by the changes of 685 BC. In a way, this might have been a screen which hid the changes at other dates and horizon locations.

We have to consider the political implications of the *Chilam Balam* statement that "the Sun returned within three heaps of years." For the shamans of the established Olmec ceremonial centers it was important to assert that they had not lost control. The statement of the *Chilam Balam* involves some hyperbole found in the original books of history from which the *Chilam Balam* was copied. I am suggesting this, because, even allowing for a number of ways in which the Sun could "return," the statement is incorrect -- the path of the Sun through the sky simply was not be the same before and after the event of 685 BC. It is true that the important zenithal sunsets of the sites all remained almost exactly the same, but the sunsets of important "era ending" dates all changed, since these were seasonal calendar dates further displaced from the equinoxes.

But the definitions of what "return" meant could be made to fit the facts. For the Olmecs the Sun's "return" was measured as its setting location along the horizon, not the day of a seasonal year that this happened. Thus when the day of a zenithal sunset again coincided with the same day as earlier after 14 Tzolkin years, rather than the expected 20 Tzolkin cycles, the statement could be made that the Sun had returned. The fact that in the months close to the solstices the Sun definitely set at a different horizon location from before 685 BC seemed not to have mattered. The difference in the horizon location of the solstice sunsets had, in fact, changed by seven degrees. To us this would be an important consideration.

Some Background

Obviously, we should be able to determine if the locations of the alignments before 685 BC were different from today's locations. This is actually easy to do. At 20 degrees latitude, in the Veracruz region, the Sun sets at the summer solstice at 25.1 degrees north of west -- under the current condition of an axial inclination of 23.5 degrees. At the earlier axial inclination of 30 degrees, the Sun would set at 32.1 degrees north of west. The difference is seven degrees. This should be clearly seen in some of the oldest Olmec sites. If, that is, the solstice location was of any significance in the philosophy of the Olmecs. Unfortunately, it was not. Nowhere in Mesoamerica are solstices ever celebrated.

[Image: Limit of sunrises and sunsets today. Plan view.]

As noted above, I started this investigation with information from Vincent Malmstrom's book *Cycles of the Sun, Mysteries of the Moon*, which suggested solstice alignments for all the ceremonial sites in Central America.

And here is the crux of my investigation and the reason I pursued this investigation: If Malmstrom, in his investigations, had found alignments which differed by 7 degrees from his expectations, I am sure he would have discarded this information out of hand. For this reason I wanted to recheck all the data on alignments that he had developed. In this process I checked alignments against every notable mountain and volcano in the Veracruz coastal region and in the Central Valley of Mexico, even if the mountains were not visible from a site. This has revealed some interesting alignments, but, despite Malmstrom's claims, only one suspected solstitial alignment among some seventy alignments. I did find some "August 13" alignments (which Malmstrom also promotes), but most often as August 12.

Accuracy is a problem. I should point out that in the 182 days that it takes the Sun to travel from the locations of the winter solstice to the summer solstice, the Sun only travels 50 degrees along the horizon from south to north (today). Thus the setting location of the Sun moves only 1/4 degree per day on average, which is equivalent to half the width of the Sun. As the solstices are approached, the Sun moves only imperceptibly.

Malmstrom suggests that an error of up to two degrees should be allowed in the alignments. But this cannot be applied, for the claim for an August 13 alignment date could then be understood as having eight days of leeway on either side of August 13. I doubt if Malmstrom meant this for the August 13 alignments he had discovered, but I cannot tell from the text. I have generally demanded an accuracy of one third of a degree (which is about equal to the numerical difference between a sunrise alignment and a sunset on the same day), rather than a margin of two degrees. [\[note 5\]](#)

On the other hand, Malmstrom also describes the shadow gnomon used to determine the exact day, July 25, that the Sun passes overhead at the ceremonial site of **Edzna** in the Yucatan, at a latitude of 19 degrees and 40 minutes north. The following day, July 26, was

celebrated as New Year's Day by the Maya. Because the method of finding this date involves a circular pillar gnomon, and not a setting Sun alignment along the horizon, it is dead accurate.

Malmstrom states that **Edzna** is the only Maya ceremonial center at this latitude. The contemporaneous city of **Teotihuacan** in the Valley of Mexico, however, is also at the latitude of 19 degrees and 40 minutes. The ceremonial center of **Edzna** is also aligned to the setting of the Sun on August 13th (actually, August 12th) with the use of an off-north axial alignment of the site. These two alignments (July 25, August 12) can also be found at **Teotihuacan**, the largest ceremonial center in the Americas, and one of the three largest cities in the world at its time, which may have had much more influence in determining observation of the calendar among the Maya than **Edzna**.

Other Considerations

One distinct advantage I have had is that field trips to Mexico were not needed. The latitude and longitude of archaeological sites and of any mountain are readily available today. They were not available in the 1970s and 1980s when Malmstrom made his investigations. (*Cycles of the Sun, Mysteries of the Moon* was published in 1997; the investigation dates from a decade earlier.)

A second problem lies in differentiating some "old alignments" from "new alignments" when numeric values are close. Luckily, most sites use a number of important alignments, so that single questionable alignments can be identified as to which period they belong.

Last, dating is somewhat of a problem. Archaeologists will support the earliest date as an indication of site occupation, which may have nothing to do with monumental construction at the sites. I have used iconography for estimates on dates of construction at Olmec **La Venta**, where the imagery and alignments of the construction of the ceremonial site (which is visible today) clearly dates the latest construction to after 685 BC, although C-14 dates suggest occupancy of the area by 900 BC.

For most other sites I have used available archaeological dates. This at times allows determining the inclination of a site to adopting one set of alignments over another. Only in a few instances do occupation dates go against a sensible timetable for the adoption of newer alignments. I'll indicate these.

Dates and Alignments

All the archaeological dates for founding, construction, and destruction of major sites match the formal expectations for the occupancy of ceremonial sites based on the concept of the "may" first developed by Munro Edmonson and expanded on in Chapter 33, "The day of Kan."

The following is a summary of sites, dates, and alignments. In looking over the following data, keep in mind that for locations from 14.5 degrees latitude through 20 degrees latitude the summer solstice alignments (sunrise or sunset) vary only from 24.3 to 25.1 degrees north of east or west. August 13 alignments would vary from 15.2 to 15.7 degrees north of east or west. Alignments are shown for both the current arrangement of the skies (23.5-degree inclination), and the previous arrangement, before 685 BC (30-degree inclination of the polar axis).

Note also that, for example, if the Sun rises some number of degrees north of east, it will set at the same number of degrees north of west -- within one quarter to one third of a degree.

Last, there are numerous clear instances of antipodal alignments. An antipodal alignment is one which is an equal number of degrees above or below the east-west cardinal direction, and would point to a sunset or sunrise location in the opposite direction, across the site.

[Image: Antipodal alignment example. Plan view.]

To ease the task of reading the following data, let me propose the important dates and horizon locations which we are looking for (or which have been discovered). The angles shown below are for a sunrise or sunset as so-many degrees north or south of east or west. That is, south of the east-west direction in fall and winter, north of the east-west line in spring and summer.

Angles of the list below are approximate, since they vary somewhat with the latitude of the site. The angles are shown for both an axial inclination of 30 degrees and for 23.5 degrees. The overhead (zenithal) passage of the Sun is also listed below. The dates are all shown as Gregorian equivalent dates. Reasoning for the selection of certain dates is detailed further below.

At this point we have a great number of instances which can be identified as marking the culmination of the Pleiades. The sequence should point to a history of the ceremonial centers. But of course old forms can be reinstituted, and established forms can be used for a long time

beyond their currency. The codification of the "Day of the Dead" by **Teotihuacan** in circa AD 200 or 400 lasted to AD 1550. So the list should be used carefully. Below a list of Pleiades culminations is reproduced.

Sunset in Degrees North of West for Various Dates		
For an axial inclination of ...	30 degrees	23.5 degrees
End of era 3114 BC, August 12	19.9 degrees	14.9 degrees
End of era 2349 BC, September 8	6.6 degrees	5.2 degrees
End of era 1492 BC, April 19	15.3 degrees	12.0 degrees
End of era 747 BC, February 28	11.0 degrees	8.6 degrees
Solstice before 685 BC	32.0 degrees	25.0 degrees
Jupiter active, July 9, 685 BC	30.4 degrees	23.7 degrees
Jupiter plasmoid, July 14	29.4 degrees	23.0 degrees
Delivery of plasmoid, July 26	26.6 degrees	20.7 degrees
Zenithal, August 9 - 14	20.3 degrees *	
July 23 - Aug 1		20.3 degrees *
* varies with latitude		

Infrequently, the angle for some one event might be confused with another event. For example, the angle of 15.3 degrees (April 19, before 685 BC) is close (0.4 degrees) to the angle of 14.9 degrees (August 12, after 685 BC). We should be able to select the appropriate event from the age of the site, or the use of other alignments. The angle of sunset for zenithal passage at any of the sites, by the way, remains almost exactly the same before and after 685 BC.

... where these dates came from

Mostly the dates are developed in this chapter, in the text further below. But let me explain some of them beforehand. The following is data for 13 Olmec and Valley of Mexico sites only.

- **August 12, 3114 BC** -- The date celebrates the completion of the "second creation" and thus the start of the "third creation" in 3147 BC, but retrocalculated as 3114 BC by the Olmecs after 747 BC. (The first creation spans 10,900 BC to 8347 BC.)

This date first shows up at **La Venta** (for an axial inclination of 30 degrees) and then at **Teotihuacan**.

- **September 8, 2349 BC** -- The date celebrates the completion of the era ending in 2349 BC, the fall of the Absu (the flood of Noah) and the end of the "third creation" of the Olmecs and Maya -- when the Pleiades first became visible. This date represents the reappearance of Jupiter on September 8, two and a half days after the arrival of the plasmoid from Venus (two days after the actual date of the autumnal equinox on September 6).

Five sites, most dating to about 600 BC or earlier, clearly use the setting sun as the alignment of September 8. Three other early sites, plus one from the above, use the actual horizon setting location of the Pleiades on October 8 to October 10 for 685 to 600 BC. Three sites institute alignments for the setting of the Pleiades in about 100 BC. Five later sites use the horizon setting location of the Pleiades on October 22 of AD 200 (some in addition to the

sunset date for September 8). In total there are 21 alignments for the event of 2349 BC. This is to be expected, since the completion of the "third creation" was probably the most important event of the past. [\[note 6\]](#)

The remembrance of 2349 BC is celebrated worldwide (as the "Day of the Dead") with the culmination of the Pleiades, although the calendar dates have changed. The culmination of the Pleiades moved later into the year after 685 BC, at first to about October 8th because of the change in the equatorial, and then further into the fall because of the precession of the equinox. By 600 BC the Pleiades culminated on October 10th.

Precession makes horizon angles which may have celebrated this day difficult to find, because they are dependent on the date at which they were selected, and thus depend on the year that a ceremonial center was built. However, many sites can be identified with a later culmination date of the Pleiades which had apparently been codified to a set calendar date, like the Christian All Saints and All Souls days. These dates are found, not from sunsets, but from the actual locations of the setting of the Pleiades in the west. The last date (October 20 - 21), set in AD 200 to AD 400, was still in use in the 16th century AD.

Horizon setting angles of the Pleiades after culmination:

- Culmination 685 BC, Oct 8 Gregorian -- 13.0 degrees
- Culmination 600 BC, Oct 10 Gregorian -- 13.6 degrees
- Culmination 200 BC, Oct 14 Gregorian -- 15.8 degrees
- Culmination AD 100, Oct 18 Gregorian -- 17.1 degrees
- Culmination AD 200, Oct 20 Gregorian -- 18.1 degrees
- Culmination AD 400, Oct 21 Gregorian -- 18.7 degrees

The angles for the setting of the Pleiades were determined by visual inspection, and should be considered approximate (that is, within a half degree). They are for midnight at **Mexico City**, thus somewhat south of **Teotihuacan** and north of the main Olmec sites in latitude.

[\[note 7\]](#)

[Image: Earliest Mesoamerican sites in Central Mexico. Maya sites not shown.
Modified from Malmstrom.]

Because the setting angle of the Pleiades varies with latitude as well as with the year, I have not explicitly identified these in the data below, except those which corresponded to the era of 685 BC to 600 BC and for AD 200 to AD 400. There may thus be others, although I do not think so. These two sets show up repeatedly.

- **April 19, 1492 BC** -- The date represents the Exodus of Moses. The calendar date is, first of all, from sources in the book of Exodus, but has been modified (from "the 14th of Aviv") because I am not following, for example, Velikovsky's supposition that the month of Aviv started at the vernal equinox. I am here following the suggestion of the Olmecs, that the date of the Earth shock in 1492 BC happened (or completed) a few days later. There are some 12 alignments to support this. This alignment first appears at **San Lorenzo**, which was founded after 1450 BC, and abandoned by 900 BC.
- **February 28, 747 BC** -- This date, representing the change in the length of the year in 747 BC, is firmly established from considerations of the Long Count, and it is also established with the first Olmec sites of **La Venta** and **Tres Zapotes**. Especially at **La Venta** it is significant that the alignment was revised after 685 BC to correspond to the new axial inclination of the Earth. February 28th alignments occur 9 times.
- **July 25, 685 BC** -- This date, the arrival of a plasmoid from Jupiter at the Sun, was established from the Maya New Year celebration (of July 26th) based on the observance of a zenithal passage of the Sun at **Edzna** and **Teotihuacan**. This is a firm date also. July 25 alignments occur 7 times.
- **July 14, 685 BC** -- This represents the suggested date that the plasmoid from Jupiter was released. The date of July 14 can also be derived from information of Book 10 of the *Chilam Balam*. The selection suggests a possible "day of Kan" associated with the end of an era -- the delivery of the plasmoid on July 25th. The concept of the "day of

Kan" is discussed in the following chapter. The date shows up four times among Northern Olmec sites.

- **July 9, 685 BC** -- This represents the date that Jupiter may have initially expanded in size. This date is based solely on the fact that it first shows up at **Tres Zapotes**, recurs 4 times elsewhere, and represents an adequate interval for Jupiter to have been seen with overhead plasma plumes and a lower trifurcated body -- so that these shapes could enter Olmec iconography. This date is not well supported because it would seem to represent a "beginning" rather than a "completion" of an event. This date would have to be understood as the completion of the period of death of Jupiter.

The analysis of site alignments will first look at two sites remote from the region which I investigated, **Izapa** in southern Mexico on the Pacific coast near Guatemala and **Edzna** in the eastern flatlands of the Yucatan.

Maya Izapa

- **Izapa** (14.90 degrees north latitude; 92.18 degrees west longitude), at the Guatemalan border of Mexico, is archaeologically dated at 600 BC to 100 BC. One of the busiest sites along the Pacific coast, with some 130 pyramid mounds and 89 stelae. Malmstrom assumes that the date for an earlier village, south of **Izapa** and closer to the Pacific coast, dated to 1400 BC, is applicable.

I am starting this survey of sites with Izapa because Vincent H. Malmstrom places the creation of the Tzolkin and Haab at this location, based on the fact that the Sun transits the site directly overhead on "August 13th." [\[note 8\]](#)

The problem with this statement is that it is wrong. The alignments identified by Malmstrom are incorrect. The real problem may be that this conjecture has been copied and transmitted from one document to another, including a few by archaeologists, without the simplest verification. Malmstrom slightly hedged the observation of his earliest article, "Izapa: Cultural Heart of the Olmecs?" in the *Proceedings of the Association of American Geographers* (1976), so that in his 1979 book *Cycles of the Sun, Mysteries of the Moon* he simply asserts that the Sun passed over Izapa on August 13. The quotes below are from the 1976 article and the 1979 book.

... August 13 at Izapa

Malmstrom writes in 1976:

"Thus, the southward transit of the vertical sun takes place at this latitude on August 12 - 13, and its northward passage occurs on the following April 30 - May 1."

It does not. (Perhaps he means culmination.) It happens on August 11th. I spent considerable

time checking sources, verifying the accuracy of my Qbasic "sunrise" program, and double-checking with an ephemeris program. The only conclusion I can come to is that Malmstrom had a good idea which he published in 1976, and followed it up with a book in 1979 where he was more assertive of his theory. **The data is fudged.** The first indication is that the 1976 article holds that the Sun transits the site (reaches a zenithal position) on "August 12 - 13." [\[note 9\]](#)

To have an important reason for devising an arcane 260-day calendar Malmstrom suggests that the planting season for corn was based on the 260-day interval after August 13th.

It is not. The 260-day span in the fall is the secondary planting season. The primary season for growing corn was the shorter time span of 105 days from April 30 to August 13.

But what is probably most bothersome is the chauvinism involved with the supposition that the 260-day Tzolkin calendar and the 365-day Haab calendar were discovered -- by accident -- at this location, and only since the founding of Izapa. As Malmstrom writes:

"Thus, it was possible for a priest standing atop the main pyramid at Izapa not only to calibrate accurately the length of the sacred 260-day almanac, but also, by counting the number of days which elapsed between consecutive sunrises over the highest mountain in Central America, the true length of the tropical year as well."

[Image: Izapa plan view. after Malmstrom]

What is here suggested is that these stone-age people were so intellectually handicapped that they could not count the days in a year. And when they did count 260 days from one zenithal passage to the next, they devised a system so arcane and so esoteric as to be nearly useless. The following year, as the 260-day Tzolkin falls totally out of sync with actual calendar days, another calendar is superimposed, the 365-day Haab.

How realistic is any of this? Obviously these brain-dead savages didn't know what they were doing. They could not even, claims Malmstrom, divide a fish up among three children. That puts them at the mental agility of 4-year olds. Speaking of the priest who had the brilliant idea of instituting a 260-day calendar which rotated 13 numbers against 20 names, Malmstrom offers the further conjecture on the Maya's insistence on counting time at completion rather than from the beginning:

"For someone accustomed to think in terms of entities rather than fractions, it was no more logical to conceptualize a part of a day than it was a part of a fish, a cacao bean, or a quetzal feather. It therefore must have seemed obvious that the day could not be counted until it was completed, that is, at sunset. In any event, this is the pattern of thought which Mesoamericans were to employ in all their subsequent mathematical

computations."

Missing here is any recognition that all the tribes of the Americas, from Alaska to Patagonia, used only two tenses to conceptualize the world: actions that were ongoing, and actions that were completed. As with many other languages, there is no future tense. To suggest that the initiation of the Tzolkin calendar caused all the Mesoamerican tribes to adopt the concept of "completion" is just absurd.

... volcano Tacana

Malmstrom writes, "*... the site of Izapa, as noted above, is oriented to the volcano Tacana, the second highest mountain in Central America.*"

It is not. It may be the second highest mountain, but the central axis of the site is displaced 16 degrees east of north. The sight-line to Tacana, on the other hand, is 20.33 degrees east of north. The difference is equal to two hand spans of fingers at arm's length. Not close at all.

... summer solstice

Malmstrom writes, "*the author noted that the region's highest peak, the volcano Tajumulco (4,220 meters), lies at an azimuth of 65 degrees from the ceremonial center. This azimuthal relationship is precisely that of the rising sun at the summer solstice.*"

It is not. My calculation has the volcano Tajumulco at an azimuth of 64.43 degrees, which is 25.57 degrees north of east. Solstice sunrise is at 24.36 degrees. This is off by more than a degree (two fingers wide at arm's length), a serious matter for a solstice, where the locations of sunrise and sunset move only by small fractions of a degree along the horizon. Being off by a degree means that the solstice date could be off by about 10 days.

Of course there is a problem with determining alignments due to the overall design of the site. Since it is mostly laid out along a SSW by NNE axis, there will be large differences in alignments if taken from different locations along this axis. We might suggest that there was a "center" of the monuments from which alignments were determined, but we have no idea of what part of the site was held to be the religious center in antiquity.

John Major Jenkins thinks it is the most northerly ballcourt. "*The alignment of the [northmost] ballcourt [with the summer solstice] is actually a degree or two north of where the sun breaks the horizon.*" So writes Jenkins, author of a number of books on the Maya calendar and its end in AD 2012. (<http://www.alignment2012.com>)

Jenkins was determining a winter solstice sunrise over the end of this ballcourt (in area "F" of Izapa). Here we have an independent voice suggesting that the sunrise is off by "a degree or two" from expectations.

Earlier, Malmstrom had written:

"The cone of Volcan Tajumulco, the highest mountain in Central America, marks the sunrise position at the summer solstice (June 22) as seen from Izapa."

It does not, as I have already noted. This did not keep Malmstrom from finding many other alignments for August 13th.

"... the author has found that more than forty of the oldest Mesoamerican ceremonial centers were oriented in just such a manner, including the classic Olmec sites of San Lorenzo and La Venta (paper in press)."

They were not. At **San Lorenzo** an alignment for August 13 does not exist at all. There are two alignments, at 15.05 degrees south of east and 15.36 south of west, for the axial inclination of 30 degrees, which could be confused with an August 12 alignment of 15.46 degrees south of east, at the axial inclination of 23.5 degrees. The occupation of **San Lorenzo** ended 300 years before the Earth's axis changed to 23.5 degrees, and 200 years before **La Venta**, where in 747 BC the Long Count was developed which allowed retrocalculations to be made.

Similarly at **La Venta** where two coaxial alignments near 15 degrees also point to April 19th under the condition of the Earth's axis of rotation being at 30 degrees.

There are Long Count dates in use at **Monte Albans** by 600 BC. But nothing at **Izapa**. Although **Izapa** is the busiest site for monuments, stelae, "altars," and "thrones," there are no inscribed dates, and no texts. **Izapa** is totally illiterate. It is a cartoon version of sacred history. It has been suggested that it was a trader's version of dedicatory monuments, installed after a good year or a profitable season.

[Image: Izapa alignments. Plan view.]

I should also note that an identical horizon location of sunrise (and sunset) on August 13 and, 260 days later, on April 30, is true everywhere. It is also true everywhere that any two days on the calendar which are spaced equally before and after the summer solstice will produce the same rising and setting locations at the horizon.

What, then, is significant for **Izapa**? Only the site axis and the zenithal sunrise are significant. Both point to August 11th. There are no other significant alignments here. This suggests it is so because of the great distance from the Valley of Mexico, which appears to be the epicenter of the "August 12 alignment" philosophy after 600 BC. This would thus suggest that the site of **Izapa** was selected for various religious purposes, probably even before 685 BC, but not because the 260-day Tzolkin and 365-day Haab calendars were created at this location.

What is being presented at **Izapa** is August 11 as the start of creation, based on a date retrocalculated since the establishment of the Long Count in 747 BC, which allowed this to be done, and using the August 11 version of the Long Count. It is a retrocalculation based, of course, on a year of 365.24 days, not 360 days which was the basis of the Long Count. It is slightly more complex than splitting a fish three ways.

Stela 5 at **Izapa** is likely a representation of the "second creation" ending in 3147 BC, when people are first molded. Chiapas and upland Guatemala is the region where the August 11 version of the Tzolkin is still in use today. The emphasis on the "creation" is fully expressed in the monuments and carvings at **Izapa** which depict elements of what will be recorded in the later *Popol Vuh*.

[Image: Stela 25 at **Izapa**, dated 300 BC to AD 250. This depicts the inverted crocodile of the Olmecs and Maya with the tail of a tree. The crocodile of Stela 25 faces in the opposite direction from the crocodile in Stela 5, depicted in Chapter 34, "The Popol Vuh." After FAMSI.]

Maya Edzna

- **Edzna** (19.58 degrees north latitude; 90.25 degrees west longitude) in the Eastern Yucatan, was initially dated at AD 600 to AD 900, but a settlement of 400 BC is currently suggested, with building activity dated to 150 BC, making it contemporaneous with **Teotihuacan** in the Valley of Mexico.

The Sun passes directly overhead on July 25th (89.98 degrees up from the horizon), as it does at **Teotihuacan**, which is located at the same latitude although a thousand miles (1600 km) west.

The main axis of the site is displaced 15.5 degrees east of north. This results in sight lines between structures which mark an "August 13" sunset alignment at 15.5 degrees north of west (15.63 degrees on August 12). There is no solstice alignment. The two alignments are congruent with the suggestion that the religious philosophy of **Edzna** derived directly from **Teotihuacan**.

[Image: **Edzna** alignments. Plan view.]

Olmec Sites

The two sites above are "modern" by comparison with some of the Olmec sites to be discussed below. The Olmecs had populated the **San Lorenzo** area since 1450 BC according

to recent C-14 dating.

Even in 1450 BC, the Olmecs exhibit a sophistication which we seldom allow to people we consider "primitives." In addition to the cultivation of maize on a scale which produced vast surpluses, the Olmecs cultivated the rubber tree and worked out the intricate process of various grades of rubber, from hard to flexible, and the details of producing cocoa. The agricultural surplus supported a widespread trade network, and accomplished the transportation of huge granite blocks from 150 miles (240 km) away via ocean-going ships -- to be carved into giant heads and six-foot high altars. [\[note 10\]](#)

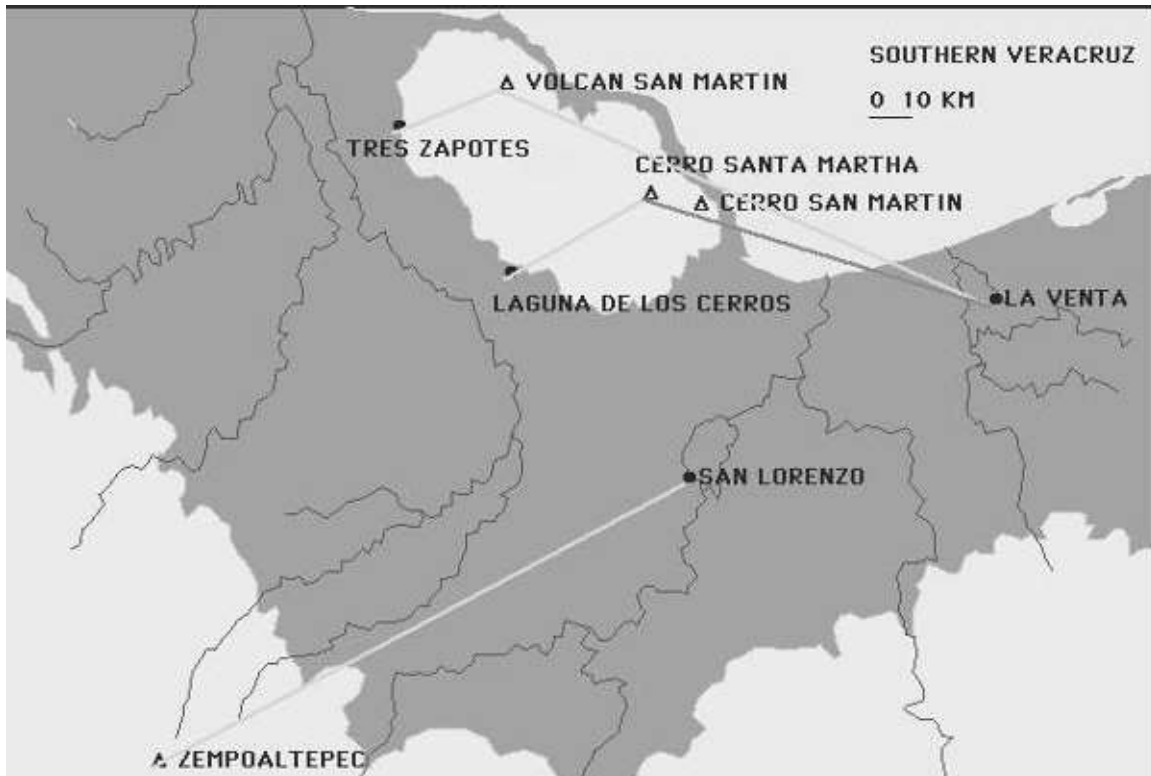

[Image: Olmec carved stone heads. After sitchin.com]

But their most outstanding effort was the production of a calendar which effectively controlled the Gods and sustained the current creation of the world. As I developed in a previous chapter, the 260-day Tzolkin calendar had been in effect since 2349 BC. This was high science, and its effectiveness was demonstrated to other tribes by the prosperity of the Olmecs.

In the region of Olmec influence, which extended into the Valley of Mexico, into the Yucatan, across the isthmus to the Pacific and south to Guatemala and Honduras, their religion, their iconography, and their "civilized attitudes" were adopted in imitation, but always localized to regional needs and concerns. Other Gods may have been added to the Olmec pantheon, but the Tzolkin was adopted without alteration, for this was science, not religion, and, like our science, was held to consist of universal truths, even while it remained integrated in the religious philosophy.

Like Thucydides, who constantly reminds his readers how the prophetess at Delphi had been correct, the author of Book 10 of the 16th century AD *Chilam Balam* includes repeated references which go to prove how events had been completed in accord with the cycles of the Tzolkin. Thus when the alignments of the oldest Olmec site, **San Lorenzo**, are investigated, it should not be surprising to find that the control over creation extends back into remote antiquity.

[Image: *San Lorenzo, La Venta, Laguna De Los Cerros, and Tres Zapotes Olmec sites, and the alignments to nearby mountains. After Vincent H. Malmstrom, "Cycles of the Sun, Mysteries of the Moon" (1997).*]

Olmec San Lorenzo

- **San Lorenzo** (17.66 degrees north latitude; 94.83 degrees west longitude) is inland from the coast in Veracruz and dated as active from 1450 BC to 900 BC. This is thought to be the oldest Olmec site, built on a huge man-made platform, which some think is shaped like a bird facing east. The ceremonial aspects of the site were destroyed in about 900 BC, although people continued to live there and at two nearby locations.

San Lorenzo site identity:

The location of **San Lorenzo** was chosen, in 1450 BC, or some 40 years earlier, as a significant site. It is immediately obvious that in the era before 685 BC the sun passed

directly overhead on the equivalent Gregorian day of August 15 and set on that day in the giant-sized volcano **Popocatepetl**, 267 miles (430 km) to the northeast, the second-highest peak in Mexico -- even though it could not be seen from **San Lorenzo**.

[Image: **San Lorenzo** alignments. Plan view.]

This suggests that the overhead passage of the Sun on a particular day (and its disappearance into a volcano) was a matter of site identity, as we have already seen for **Izapa**. Since the Sun passes overhead at every location where ceremonial sites were constructed, from Guatemala to the Central Mexican desert, it would seem of no consequence for me to note this. But it becomes significant if the locations of ceremonial sites are selected so that the sunrise or sunset for a zenithal passage of the Sun is aligned so that the Sun sets or rises at some mountain or volcano. In fact, this is the case at almost every one of the sites in Veracruz and in the Valley of Mexico.

San Lorenzo era marker:

Malmstrom suggests a solstitial alignment at 25 degrees south of west over the mountain **Zempoaltepec**. However, **Zempoaltepec** is 15.36 degrees south of west, measured from the village of **Tenochtitlan** which is a central part of the **San Lorenzo** complex.

This 15.36-degree angle with **Zempoaltepec** could have been used by Malmstrom to suggest an "August 13" alignment, but even Malmstrom would have realized that this would have been much too early historically. The "August 13" alignments do not show up anywhere else until after 600 BC. **San Lorenzo** was abandoned in about 900 BC.

The alignment of 15.36 degrees south of west with **Zempoaltepec** is equivalent to an antipodal sunrise on April 19th, on a backward extended Gregorian equivalent calendar, under the condition of having the axial inclination of the Earth (to the normal of the orbit) at 30 degrees.

Similarly the mountain **El Chichon** makes a complementary angle of 15.05 degrees south of east with **San Lorenzo**, defining an antipodal sunset for the same day of April 19th, on a backward extended Gregorian equivalent calendar, and also under the condition of having the axial inclination of the Earth at 30 degrees. **El Chichon** is 1060 meters high and could not be seen from **San Lorenzo**.

San Lorenzo discussion:

The date of April 19th surprised me at first. The "date," of course, is a horizon location, not an actual date. Although the Gregorian calendar is not applicable to the period before 747 BC, we can find "equivalent" dates based on a fraction of the orbital period. In order to distinguish this use of the Gregorian for horizon locations, I will, for the remainder of this chapter (or as applicable), list these dates as "equivalent Gregorian," as an indication of how the horizon location or equivalent date was derived. [\[note 11\]](#)

Exodus (12:6 and 13:4) reveals that the day and month of the Earth shock of Exodus (in 1492 BC) was the 14th day after the start of the month Aviv, which in turn is the "first" month of the year (Exodus 12:18), supposedly opening on the equinox, with the month started at a new moon. The Earth shock happened, says Velikovsky, based on Biblical and other sources, at midnight, and preceded the Exodus of Moses. Additionally, says Velikovsky, the equinox fell on the day of a new moon.

Exodus is not clear on when the first month (Aviv) started. The following can be gleaned from Exodus -- none of which specifically supports what Velikovsky wrote.

- Exodus 12:2, God tells Moses that this will be the first month of the year (as opposed to the traditional Egyptian start of the year near the fall equinox).
- Exodus 12:6 speaks of the paschal feast to be performed on the 14th day of the month, "between the evenings." As in Egypt, the day started at nightfall.
- Exodus 12:18 notes the extent of the seven days of the Passover feast, from the 14th day of "the first month" to the 21st.

Velikovsky may have used additional sources, but neither this nor any other text in Exodus supports his claim that this month started at the equinox, except the future location of the paschal feast in the year. It is, in fact, the start of a liturgical year. The civil year still started at the autumnal equinox.

Not mentioned by Velikovsky, Exodus 13:4 notes "this day in early spring." This would be the excuse for suggesting that the month of Aviv *might have* started on the equinox. (Aviv means "spring.") But for Aviv to have started exactly at the spring equinox is unlikely. The 14 days defines a full Moon on a 28-day lunar period. In 1492 BC the period of the Moon changed from 28 days to 30 days. We have here, therefore, a dating glitch.

I will accept the date of April 19th used by the Olmecs as reflecting the Earth shock of 1492 BC as accurate. Let me suggest also that the alignments at the site of **San Lorenzo** had been selected to coincide with the completion of the previous creation.

The "creation" event of 1492 BC (or completion of a prior "creation") does not fit well with other notions of "creations." Although the alignments were carried forward with all later ceremonial sites, little seems to have been made of the events of 1492 BC.

The end of the previous creation may have been determined by the Earth shock, or by the completion of the subsequent reaction motion of the Earth (which may have been quite long, as I have suggested earlier). It is difficult to gauge what the Olmecs might have considered as the end of a creation. This would in this case seem to add five days to what the rest of the world considered to be the start of the 1492 BC cataclysm.

The selection of the day which ends an era (rather than the start) is almost completely certain from the starting date of the Long Count in 747 BC, as well as the dates selected as important for 2349 BC (the "third creation"), and 685 BC (both of which are detailed below).

The selection of the site of **San Lorenzo** involved the selection of an alignment (two, actually) signifying the ending date of the previous creation in 1492 BC, April 19. We will see many additional sites with alignments for this date (as horizon locations). Two markers triangulate **San Lorenzo** to the date of April 19th. Here are the details:

- **El Chichon** is 1060 meters high. This mountain could not be seen. It lies southeast of **San Lorenzo**. The angle (15.05 degrees south of east) defines an antipodal spring sunset on April 19th (at 15.23 degrees north of west), at the time when the axis of the Earth was at 30 degrees.
- **Cerro Zempoaltepec** in the southwest is the 11th highest mountain in Mexico, at 3396 meters. It can be seen in the southwest from any of the **San Lorenzo** locations. The angle (15.36 degrees south of west) defines an antipodal spring sunrise, which matches the sunset angle made by **El Chichon**, for April 19th (at 15.23 degrees), at the time when the axis of the Earth was at 30 degrees.

The fractional differences in the two angles (0.31 degrees) is very close to the advance the Sun makes between rising and setting at that time of the year (an average of about 0.24 degrees in 12 hours), although admittedly, it is in the wrong sequence. In this analysis I have used "antipodal" as signifying a direction across the site, that is, an angle displaced 180 degrees from the alignment. If, however, antipodal is used in the sense of an angle reflected across the east-west cardinal direction axis, then the 0.31 degree difference is correct in signifying the difference between the horizon sunrise and sunset locations.

San Lorenzo predates the disturbances of 747 BC and 685 BC, which were architecturally recognized by ceremonial centers built after 747 BC and after 600 BC. The occupation of the mound of **San Lorenzo** was chosen to signify the end of the previous creation in 1492 BC.

Zenithal sunset:

The mountain **Popocatepetl** could not be seen from **Tenochtitlon** at **San Lorenzo**. It is the second highest volcano in Mexico. The mountain **Popocatepetl**, signaled the day (sunset) that the Sun passes directly overhead at **Tenochtitlan**, on the Gregorian equivalent day of August 15, with the Earth's axis at 30 degrees.

latitude	before 685 BC		after 685 BC		differences	
	day	angle	day	angle		
15.0	Aug 21	15.48	Aug 11	15.56	10 days	0.08 degrees
17.5	Aug 15	18.42	Aug 2	18.51	13 days	0.09 degrees
20.0	Aug 9	21.29	Jul 23	21.37	17 days	0.08 degrees

The August 15 sunset horizon location lasted past 685 BC when the axis of the Earth changed to 23.5 degrees. After 685 BC the Sun again rose and set at almost exactly the same horizon locations, but on August 2.

The return of the Sun to the same horizon location is to be expected, since the Sun moves in a set of circles which have the Earth's polar axis as their center. The fact that the Sun returned to the same horizon location for a zenithal passage, even though on a different day of the year, is true everywhere in the region, as long as the dates are not near the solstices. The following lists examples at three latitudes for the region of these ceremonial centers:

Under the condition of having the Earth's axis at 30 degrees, all the Olmec sites at latitudes of 17.7 degrees (**San Lorenzo**) to 19.4 degrees (**Zempoala**) will have the Sun pass overhead between Gregorian equivalent dates of August 15 (**San Lorenzo**) and August 10 (**Zempoala**).

After the axis assumed an inclination of 23.5 degrees, these same Olmec sites will have the Sun pass overhead between Gregorian equivalent dates of August 2 (**San Lorenzo**) and July 26 (**Zempoala**).

Thus the Sun passed overhead again 13 to 15 days earlier in the year. But in all cases, the Sun, under the new order of the sky, would set again at the same horizon location, to within a small fraction of a degree. In this manner, the Sun -- everywhere -- returned to its former path.

San Lorenzo summary:

In summary, two site alignment aspects can be assigned to **San Lorenzo** which seem to have some justification, rather than just referring to numerological magic. These two aspects, it turns out, will be true for all the Olmec and Valley of Mexico sites I looked at.

- Certain: The passage of the Sun directly overhead of the site on two days of the year, August 15 and April 29th (in this case). The alignment with **Popocatepetl**, 267 miles away, although not visible from **San Lorenzo**, would signal this date. After the later change in the polar axis of 685 BC, the Sun set again at the same horizon location (within 0.09 degrees) after passing directly over **San Lorenzo**, but on a different calendar date.
- More than a coincidence: The selection of the site at the intersection of sight lines to the sunrise and sunset of the ending date of an era on April 19, 1492 BC. For **San Lorenzo** the nearby mountains **Cerro Zempoaltepec** and **El Chichon** signaled this date. Note that both of these alignments are antipodal. This is the first use of antipodal alignments in the region.

What these alignments point out, along with the alignments noted for the more modern sites above and the additional sites described below, is that the location of a ceremonial center involves two main concerns. These are:

- Zenithal passage of the Sun; setting at a mountain
- Ending date(s) of previous era(s); setting at mountains.

There is, at **San Lorenzo**, no solstitial alignment, either in the current era, or in the previous era. If a solstitial alignment from the era before 685 BC, when the Earth's axis was at 30 degrees, had shown up at **San Lorenzo** it would have been a sunset at 32 degrees north of west. This certainly would have been evidence that the axial inclination had indeed changed. But nothing like that has been revealed.

The alignments (and this applies to alignments at other sites as well) are not simply numerical coincidences. There are only a limited number of tall mountains in this region of Mexico (mostly volcanoes, and admittedly some 40 of them for all of Mexico), and there are only 25 degrees above and below the east-west cardinal directions where the Sun could rise or set (32 degrees before 685 BC; 25 degrees after). The alignments I have found either match to within a fraction of a degree to expectations of site identity and era-ending markers, or do not exist at all. And all the sunsets are in volcanoes or on mountain peaks. The alignments show up as multiple alignments only at major ceremonial sites of acknowledged importance, not at every village or area of agricultural concentration. [\[note 12\]](#)

... navigation by the stars

A word should be said about alignments to mountains and volcanoes which cannot be seen from a site. The Olmecs were not an insular people. They traveled widely, paddling freight canoes around the Yucatan to Honduras, crossed on foot to the Pacific and traveled into Guatemala and further south. There are suggestions that eventually they traded as far north as the Southern United States. They knew the mountains of Central America for they exploited their resources. It took modern archaeologists nearly ten years to find the Mesoamerican

source of the jade which appears ubiquitously among ancient artifacts.

As such, they must have been comfortable with sight-line navigation, at sea as well as on land, so that it would be easy to determine the location of a mountain even when it was hundreds of miles out of view. A mountain which had disappeared from view could be located from a knowledge of intermediate landmarks. (Any Boy Scout can do this also.) Additionally, once a distant mountain was located against a setting star or an overpassing star, it could be located, even when out of view, for in the tropics the stars deviate only minutely in their setting location at the horizon over the year.

Mauricio Obregon, in *Beyond the Edge of the Sea* (2001), describes navigation in antiquity. The book includes a section on stellar navigation in the tropics, applied to Polynesia. This would also apply to Mesoamerica. He demonstrates how, over the range of tropical latitudes, the rising and setting locations of stars move very little over the course of the year.

And, as likely, the zenith location of stars was used. Obregon discusses this for navigation in the Mediterranean. Since the stars do not deviate from their position (unlike the Sun), every port would have a series of stars pass directly overhead which would always be the same, although different stars would do this at different hours of the night, and the sequence would shift throughout the year. Any port could be located from one or more associated stars. Ports could be found longitudinally by sailing to the location of the highest position of these stars in the sky. This would place the ship either directly north or south of the port. After this it would be a matter of sailing north or south under the guidance of the polar stars. But anyone familiar with the travels of the stars in the night sky could have navigated to the port of destination on an angle. In the *Odyssey*, Homer, as a display of the modernity to come, has the Phaeacians, who are returning Odysseus to Ithaca, row during the night and make landfall in the morning.

It seems very likely that the Olmecs also used stellar navigation not unlike what the Polynesians used -- these are the same latitudes. Considering the measures taken in Mesoamerica to align ceremonial sites with the overhead passage of the Sun, which would happen only on two days of the year, it could also be suggested that ceremonial sites were located not just by aspects of the Sun's travels, but by the passage of zenithal stars. We know for sure that the location of **Tula** (after AD 900) was selected to be directly below the zenithal passage of the Pleiades. [\[note 13\]](#)

Olmec La Venta

- **La Venta** (18.1 degrees north latitude), in Tabasco, is dated from 1160 BC (destroyed in 400 to 300 BC). Consisting of a fluted pyramid, additional berms, mounds, and plazas in line with this, and buried giant greenstone tile floors representing images of the face of a jaguar, laid out to read "nine" (like in Bolon Dzacab, "Nine Lives"). The site includes four gigantic stone heads, five "creation altars" (a total of 8 giant altars), five elaborate

burials. A long site, it is built on an axis of 8 degrees west of north.

Malmstrom notes, "*The latter feature [aligned 8 degrees west of north] has intrigued archaeologists but has never satisfactorily been explained by them,*" and proceeds to list some astronomical explanations proposed in the past, none of which hold water.

A satisfactory explanation is that the alignment of 8 degrees west of north for **La Venta** represents a sunset at right angles for February 28th (at 8.6 degrees south of west; 8.2 degrees on March 1). This is the date after the Earth shock by Mars in 747 BC, the day on which the Earth's year increased to the current 365.24 days, and the date on which the Olmecs instituted the Long Count calendar. This is immediately obvious in looking at this alignment.

[Image: **La Venta** ceremonial center. After Nigel Davies, "*The Ancient Kingdoms of Mexico*. (1982). The plan view has changed somewhat with additional excavation.]

A number of other locations also use the 8 degrees west of north alignment, including the Maya ceremonial center of **Tikal**, built almost a thousand years later. By that time the use of an 8-degree site alignment had become a traditional aspect of ceremonial center construction.

[Image: La Venta alignments. Plan view.]

Note that with the Earth's axis aligned 30 degrees to the normal of the orbit, the sunset location for February 28th would not have been at 8 degrees south of west, but at 11.00 degrees. This, in fact, is the angle between **La Venta** and **Popocatepetl**. It defines an antipodal sunrise for the day of February 28th in the era before 685 BC.

There are two additional alignments with the mountains **Citlaltepetl** (15.22 degrees north of west) and **Volcan La Malinche** (15.32 degrees north of west), in direct line with each other, which define a sunset on April 19 (15.27 degrees), for a 30-degree axial inclination.

These last two recall the dual alignment used at **San Lorenzo** for the same era-ending date. But at **La Venta** this duplication is incorporated by having another volcano, **Volcan La Malinche**, almost exactly in line (coaxially) with **Citlaltepetl** -- within 0.1 degree. Not a single one of these mountains can be viewed from **La Venta**.

These two different alignments also suggest the selection and the first occupation of **La Venta** dates from after 747 BC. This is revealed also by the fact that there definitely is an old alignment for February 28. This was selected while the axial inclination of the Earth was still at 30 degrees. The occupation of the site by farmers, dating to 900 BC, has no bearing on this.

Sixty-two years later, after 685 BC, the pyramid and other constructions were started, aligned, as would be appropriate at that time, to 8 degrees off the north cardinal direction in order to again locate the sunset of February 28th. What this suggests is that the location of the ceremonial center incorporated features dating from before 747 BC, but the construction of the ceremonial center which we see today dates to after 685 BC, when alignment corrections were made. All of the iconography of **La Venta** supports this last. The iconography, in fact, deals exclusively with the event of 685 BC, not the Earth shock of 747 BC.

The 15.27-degree north of west alignment (the April 19th alignment) could be held to represent an August 12 alignment in the current era (which would be 15.49 degrees north of west). The age of the site in general, and the site selection alignment to the date of February 28 under the condition of a 30-degree axial inclination of the Earth, argue against an August 12 alignment as an initial condition.

When the axis of the Earth changed after 685 BC, the current monumental construction was started, aligned at a right angle to the new horizon location for the date of February 28th. Additionally, the prior alignments to April 19 (as I pointed out above) could then be used as an alignment to August 12. What is missing are any alignments reflecting the events of July of 685 BC.

The monuments themselves clearly express what was seen in 685 BC: Jupiter with a giant

coma and standing, as it were, on the inverted head of a crocodile, which finds expression in engraved celts and stelae. The apparition in the sky was also understood as a mountain or volcano. This becomes the first pyramid to be constructed in Mesoamerica. "Pyramid" or "man-made mountain" is transliterated from the Quiche, as in Mayan, as "red-house" (Tedlock). Later Post-Classical Maya will express this image, through influences from the Valley of Mexico, as a "Flower Mountain" -- another very appropriate image.

La Venta site identity:

Site-identity was accomplished with an alignment with **Volcan San Martin Tuxtla** in the northwest. With the axis at 30 degrees, the Sun passed directly over **La Venta** on the Gregorian equivalent day of August 14, setting at 18.93 degrees north of west. In the present era, with the Earth's axis at 23.5 degrees the Sun passes overhead on August 1, 13 days earlier.

La Venta notes:

What we have at **La Venta**, as was seen also at **San Lorenzo**, are site alignments serving two purposes. First, the alignment of the setting Sun with a mountain on the day it passes overhead.

Second, the alignment of the site with a mountain which recognizes the era-ending dates of the previous creations or re-creations of the world. At **La Venta** this additional alignment recognized February 28th, 747 BC.

After 685 BC this was altered. Mountains can't be moved, but the site could be realigned. After 685 BC the site was rearranged (rebuilt) on an axis which celebrated a new horizon direction for the ending of the era in 747 BC. (The horizon location of the setting of the zenithal Sun remained the same.)

The solution of using the axis of a site to point to a horizon location at right angles will be seen again at **Teotihuacan**, built 400 years later, where it is quite obvious. A thousand years later the Maya use the site axis of their centers and the axis of individual structures for the same purposes. I have no data on axial alignments of most other sites of the Olmec coastal area or the Valley of Mexico, since I lack specific site maps.

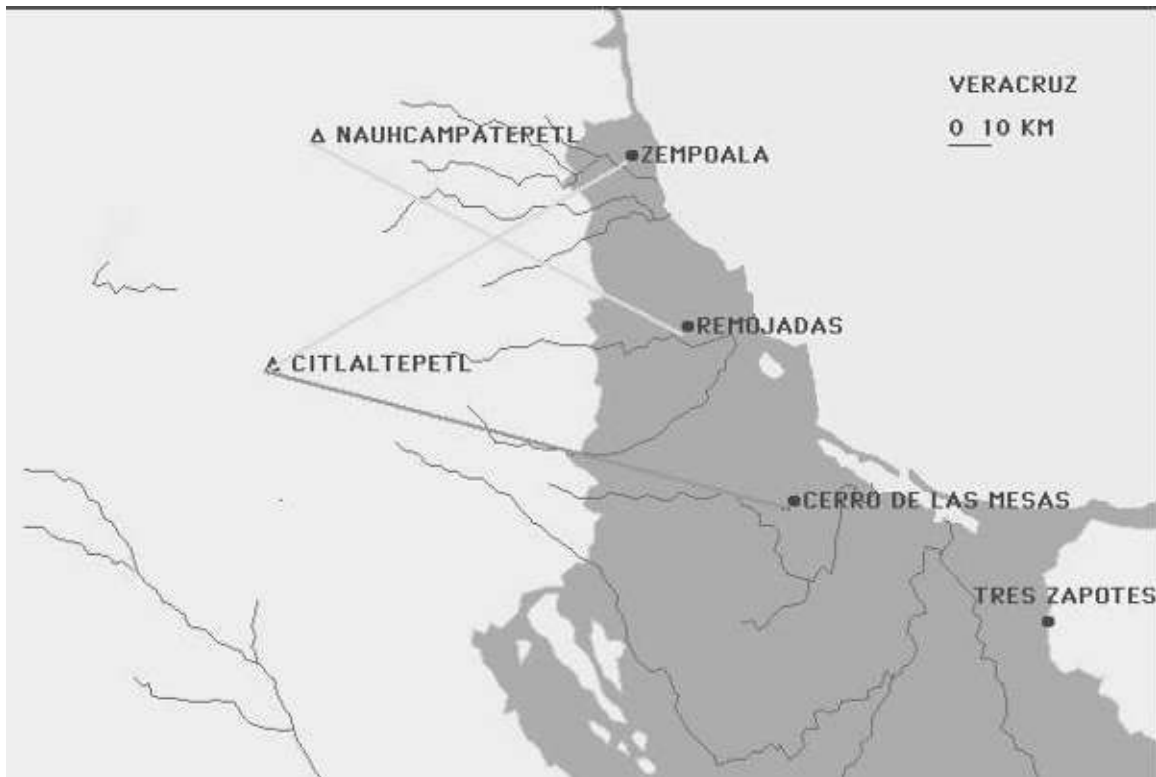

Alignments pointing to April 19, 1492 BC, occur at the Olmec sites of **San Lorenzo**, **La Venta**, and **Cerro De La Mesas**, and can also be implied for **Laguna de los Cerros** and **Tres Zapotes** -- all conformed to a 30-degree axial inclination. These also occur at three sites in the Valley of Mexico. At the important site of **Cholula** in the Valley of Mexico, the horizon location for April 19 is defined under the condition of the current inclination of the Earth's axis.

But it could be suggested that after 685 BC the alignments pointing to April 19 (15.22 and 15.32 degrees n of w), which were in use almost universally at other sites, and correct for the era before 685 BC, could have been reassigned for the era after 685 BC to designate the date of August 13 (15.49 degrees). [\[note 14\]](#)

Other Olmec and Valley of Mexico Sites

I have looked at site alignments for the additional Olmec sites along the coast, **Tres Zapotes**, **Cerro de la Mesas**, **Remojadas**, **Zempoala**, and **Laguna De Los Cerros**. (Nothing interesting was originally found at **Laguna De Los Cerros**.) I also looked at the Valley of Mexico sites of **Tlatilco**, **Tizatlan**, **Ciocuilco**, **Tlapacoya**, **Cholula**, and **Teotihuacan**.

I expected somewhat of a logical progression of alignments among the Olmec sites, and a later progression in the Valley of Mexico. I expected to see the abandonment of alignments for ancient era-ending dates, and an adoption of newer era-ending dates. Nothing like that came clearly to light. What is seen instead is a continued, although somewhat sporadic, use of the alignments for the older era-ending dates (3114 BC, 2349 BC, 1492 BC and 747 BC), some of which almost seemed to have become mandatory, and a genuine confusion of the dates from the year 685 BC. A few notes on some sites follow.

[Image: **Cerro De Las Mesas**, **Remojadas**, and **Zempoala** Olmec sites, and the alignments to nearby mountains. After Vincent H. Malmstrom, "Cycles of the Sun, Mysteries of the Moon" (1997).]

Tres Zapotes

- **Tres Zapotes** (18.4667 north; 95.4333 west) Founded sometime in the centuries well before 1000 BC, **Tres Zapotes** became a regional center after about 900 BC, coinciding with the decline of **San Lorenzo Tenochtitlan**. **Tres Zapotes** was completely abandoned by AD 900.

Tres Zapotes site identity:

The site-identity alignment consists of an angle of 19.67 degrees north of east for a sunrise over **Volcan San Martin Tuxtla**. This represents the day the Sun passes directly overhead on August 13 of the previous era (before 685 BC), at 19.67 degrees north of east, rising out of a volcano.

Tres Zapotes era markers:

The angle of 11.41 degrees south of east with **Cerro Santa Martha** (Veracruz) represents the era-ending for 747 BC (11.02 degrees), conformed to the previous axial inclination. (Although it could represent April 19, 1492 BC, conformed to the current era.)

In addition **Tres Zapotes** recognizes both July 9th, the day Jupiter expanded in 685 BC, and July 25th, when the plasmoid struck the Sun. The first date with an alignment with **Nauhcampatepetl** for a summer sunset of July 9th, the second date is signaled with two alignments, one as a sunset over **Cerro San Martin**, and the other as the antipodal value of this over **El Chichon**. All of the horizon locations define dates according to the previous axial inclination of 30 degrees.

Tres Zapotes discussion:

Considering that **Tres Zapotes** is a very old site, and may have taken over the ceremonial functions of **San Lorenzo**, it may perhaps be expected to find alignments for the era-ending for February 28, 747 BC conformed to an axial inclination of 30 degrees. But to also find alignments for July 9th, July 25th, and August 12th all conformed to a 30-degree axial inclination, makes little sense if the founding of **Tres Zapotes** was after 747 BC but before 685 BC.

The alignments at **Tres Zapotes** are complex. We could ask, How did the Olmecs do this? The Olmecs had the Tzolkin calendar and a heightened sense of geography. And they were not primitives. They had lived in these regions for thousands of years. And they had hundreds of years to locate and select sites for ceremonial centers. It is, in fact, only the major ceremonial centers which managed to adorn themselves with all the important

alignments.

If two mountains could be found which coaxially represented, for example, an era-ending date in conformity to either an axial inclination of 30 degrees or 23.5 degrees, then the line connecting them defines a series of possible sites. A location along this line could be found which might indicate additional important horizon locations. Given a hundred years to do this, and a fine sense of geography, this is not all that difficult. I'll present further details of this site in the next chapter.

Cerro De La Mesas

- **Cerro De La Mesas** (18.7167 north; 96.15 west) "hill of the altars" is an archaeological site in Veracruz, in the Papaloapan river basin. It was a prominent regional center from 600 BC to AD 900, and a regional capital from perhaps AD 300 to 600.

Cerro De La Mesas site identity:

The Sun passes overhead on August 12th, which is also the August 12 era-ending for 3114 BC for the era before 685 BC, but there is no mountain at 19.73 degrees for an alignment.

There is an alignment with **El Chichon (Chiapas)** which constitutes an antipodal alignment for a summer solstice sunset in the current era. This is the first instance of a solstitial alignment, but it may be a coincidence.

Cerro De La Mesas era marker:

There is an alignment with **Volcan La Malinche** defining a sunset on April 19, 1492 BC (15.32 degrees), and an antipodal alignment with **Cerro Santa Martha** (Veracruz), also for April 19 (15.81 degrees), both conformed to a 30-degree axial inclination.

Additionally there is a summer sunset over **Ixtaccihuatl** which defines an antipodal winter sunrise for February 28th, 747 BC (11.04 degrees), also conformed to a 30-degree axial inclination.

Cerro De La Mesas discussion:

Here at **Cerro De La Mesas** we see the first summer solstice, but for the current era. Because all the other alignments are based on an axial inclination of 30 degrees, I think this solstice alignment is a coincidence. There will be two other solstice alignments among the 13 sites, but both will be conformed to a 30-degree axial inclination.

Remojadas

- **Remojadas** (18.9833 north; 96.3167 west) is dated from 100 BC to AD 800 (perhaps). The site has remained largely unexplored.

Remojadas site identity:

An angle of 31.47 degrees north of west with **Nauhcampatepetl** defines a summer solstice (31.92 degrees) in the previous era, for an axial inclination of 30 degrees. This would be clear evidence of a change in the inclination of the Earth's axis, but I think it is spurious, for all the other alignments are for the current era.

Remojadas era markers:

A complete array of era markers is presented -- September 8, 2349 BC, February 28, 747 BC, July 9th, 14th, and 25th of 685 BC. All of these are presented under the current condition of a 23.5-degree axial inclination.

Zempoala

- **Zempoala** (19.447 north; 96.408 west). Active 100 BC to AD 800. Not well explored.

The era marker dates of September 8, 2349 BC, and February 28, 747 BC, and for July 25th, 685 BC, are all presented with alignments based on an axial inclination of 30 degrees. The site identification consists of a zenithal passage on July 26th, although the alignment is also one of the important dates from the year 685 BC.

The Valley of Mexico

- Malmstrom shows six sites with "solstice alignments" in the Valley of Mexico, including **Teotihuacan**, with alignments to the mountains **Ixtaccihuatl**, **Citlaltepētāl**, and **Popocatepetl**.

I have checked alignments against the 5 Valley of Mexico volcanoes and 6 coastal mountains.

- The angle made between any of these sites and the horizon location of sunrise (or sunset) at the solstice would be about 24.9 degrees. None were found.

One exception might be the possible solstitial alignment for the prior era when the Earth's axis was still at 30 degrees, found at **Cholula**, which I think is a coincidence.

- An August 12 alignment after 685 BC would be about 15.6 degrees. None were found, with the exception of the site-axis alignment of **Teotihuacan**.

There might be other alignments to August 12, determined by the divergence of the major axis of a site from a cardinal direction, but I do not have site plans available.

- Zenithal passage, between late July to early August, would be at an angle of 19 to 20 degrees. Three were found, including **Teotihuacan**.

What was found instead were numerous "era-ending alignments" -- some 22 for the six sites that were investigated.

The City of Teotihuacan

- **Teotihuacan** (19.683 degrees north latitude; 98.85 west longitude) in the Valley of Mexico, is dated at 150 BC (or 200 BC) and was one of the largest cities in the world, lasting to AD 700, when it was destroyed. The site is offset to the east from directly north by 15.5 degrees.

Teotihuacan site identity:

As mentioned above, on July 25th the Sun passes directly overhead. This is an era-ending marker in addition to being a site identity marker.

Anthony Aveni claims, in *Skywatchers of Ancient Mexico* (1980), that at **Teotihuacan** the Pleiades set at "about" 15.5 degrees north of west after culmination, and in circa AD 150, which would be at a right angle to the Street of the Dead (the main axis of the site).

"To a degree," writes Aveni. This is not even nominally correct, for the date of AD 150 is too early, and the angle is off by 3 degrees. It is not a 15.5-degree normal to the main axis.

[Image: **Teotihuacan** alignments. Plan view.]

The setting of the Pleiades is, in fact, represented with two antipodal alignments -- to **Volcan San Martin Pajapan** (18.65 degrees) and **Cerro Santa Martha (Veracruz)** (18.45 degrees). Both of these are correct for the era of AD 200 to 400. [\[note 15\]](#)

I have identified the existing right angle as an August 12 alignment.

Teotihuacan era marker:

The main street is clearly oriented at a right angle to an August 12 sunset location (15.6 degrees north of west). The Temple of the Sun at **Teotihuacan** forms one side of a giant ballcourt with the horizon location where the Sun sets, on August 12, forming the other side. The Sun is the ball or perhaps the ball player, on August 12.

The site is additionally oriented to a winter sunrise over the near mountain **Citlaltepētł** in the southeast (which cannot be seen from **Teotihuacan**). This angle with **Citlaltepētł**, the highest mountain in Mexico, suggests an antipodal sunrise on July 15th (22.83 degrees), and may represent the day after July 14th.

As mentioned above, there are two antipodal alignments to **Volcan San Martin Pajapan** (18.65 degrees) and **Cerro Santa Martha (Veracruz)** (18.45 degrees). Both reflect an alignment for the setting of the Pleiades after culmination on October 20 or 21, Gregorian.

Teotihuacan additional notes:

Curious as this might seem, there are many antipodal alignments to be found at other sites, as at **Teotihuacan**. This type of alignment has been remarked on by archaeologists (who

normally pay little attention to things like this). Considering the twist in geometry which is accomplished by having the right angle direction of the main axis at **Teotihuacan** point to an important horizon location, the use of antipodal alignments is not unexpected. Antipodal alignments were first used at the oldest site in this region, **San Lorenzo**, discussed above. The antipodal alignment in this case points in the direction of the angle below (south of) the east-west direction which is equal to the proper angle above the east-west direction. It thus points to a summer sunset in the reverse direction (and two for the setting of the Pleiades).

There is no solstitial alignment at **Teotihuacan**.

Monte Alban

- **Monte Alban** (17.044 degrees north; 96.768 west) is dated from circa 600 BC to circa AD 1100 and is located considerably southeast of the Valley of Mexico, in the mountains of Oaxaca and on a mountain top. Although it continued to be occupied until the Spanish invasion, **Monte Alban** went into a steep decline after AD 700. Remodeled in about 275 BC to be aligned at 5 degrees east of north, except for one building which retained the original alignment of 15.5 degrees east of north, and thus indicates an original alignment to an August 13 sunset. (from Malmstrom)

Monte Alban used a fixed Tzolkin calendar, starting on August 14, which repeated a smaller portion after the first 260 days. This was related to Malmstrom by archaeologist David Peterson working at **Monte Alban**.

The site's axis angle of 5 degrees east of north is at a right angle to a sunset on the day of September 8 (5.16 degrees sunrise) for the period after 685 BC. There are many alignments for the date of September 8 among Olmec sites and in the Valley of Mexico, both for the current 23.5-degree axial inclination and the prior 30-degree axial inclination. September 8 is an "era-ending" horizon location for 2349 BC -- the "Day of the Dead." It signifies the day of the culmination of the Pleiades in the era before 685 BC, when the axis was still at 30 degrees.

Malmstrom writes:

*"Peterson ... notes that that Mound J, the arrowhead-shaped structure near the southern end of the main plaza, appears to have been constructed to commemorate the azimuth of the sunrise on the days of the zenithal sun passage over **Monte Alban** (May 8 and August 5), the alignment of its original front steps having been 72 degrees."* [\[note 16\]](#)

The alignment of the steps at 72 degrees (azimuth) is 18 degrees north of east. This defines the date of August 4 (August 5 in the quote above), when the Sun overpasses **Monte Alban** at 89.94 degrees above the horizon, rising at 17.89 degrees north of east. It is a marker for the site identity of **Monte Alban**. In the era before 685 BC, with the Earth's axis at 30 degrees,

the zenithal passage of the Sun over **Monte Alban** happened on August 16. More on the changes at **Monte Alban** in the following chapter. [\[note 17\]](#)

Monte Alban was certainly the center of fervent intellectual activity in Mesoamerica after 600 BC. The Zapotecs adapted the Olmec calendar to their own philosophies, including the establishment of a fixed calendar which repeated annually, the introduction of a leap day, the placement of a ceremonial center on a mountaintop (which no one else ever did), the development of an extensive script, application of the Long Count notation, and the adoption of a very characteristic local style of architecture and decor. [\[note 18\]](#)

Rebuilding the site in about 275 BC, from an alignment of 15.5 degrees east of north to an alignment of 5 degrees east of north, was a rejection of the Olmec philosophies, and a return to older, and perhaps local and more correct, traditions. **Monte Alban** was the longest-lived ceremonial center in Mesoamerica, lasting 1700 years until taken over by the Mixtecs in about AD 1100 (to continue an additional 400 years).

Divergent Alignment

There are some groupings of alignments which do not correspond to known dates or easily assigned dates. Any alignment can generate four separate dates, two in the spring and summer, and two in the fall and winter season.

... 27 and 29 degrees

Alignments at angles of 27 to 29 degrees are associated with 6 sites, but no consistent dates show up. The data follows. All the calculations are for an axial inclination of 30 degrees, since these angles would be out of range for an axial inclination of 23.5 degrees.

site	angle	direction	actual date	actual angle
San Lorenzo	29.78	n of w	July 12	29.60
Laguna d l Cerros	28.35	n of w	July 18	28.34
Cerro d l Mesas	27.96	n of w	July 20	27.94
Remojadas	27.91	s of e	July 20	27.98
Tlatilco	28.74	s of e	July 17	28.83
Teotihuacan	28.84	s of e	July 17	28.88

It might be that the dates of July 17 and July 18, and even July 20, were meant to indicate the date of July 14th, as used at other sites to represent the release of the plasmoid from Jupiter. It could be suggested, for example, that local records of the event were divergent in determining the actual date, since this was an event which took place in the far reaches of space, and might not have been seen accurately.

On the other hand, the alignments at 27 to 29 degrees are probably all spurious. None of the sites duplicate these horizon locations to have two mountains fall in line for an alignment (a

coaxial alignment), as happens frequently at many locations.

... 13 and 18 degrees

The following are four sites with 13-degree alignments, all with alignments are within 0.3 degrees of 13.1 degrees.

--- site alignments at 13 degrees ---		
site	angle	direction
La Venta	12.79	n of w
	13.27	n of w
Tres Zapotes	12.56	n of w
	13.39	s of e
Tlapacoya	13.44	s of e
	13.16	s of e
Tlatilco	13.31	s of e
	13.00	s of e
possible dates	-- 30 degrees --	-- 23.5 degrees --
n of e or w	Apr 15, Aug 26	Apr 22, Aug 19
s of e or w	Feb 24, Oct 15	Feb 16, Oct 23

All the alignments point to the southeast or the northwest, and all four sites use coaxial alignments. But the dates make no sense in terms of expected sunsets on important dates. Below are the sites with 18-degree alignments: These five additional sites have seven alignments grouped within 0.4 degrees of 18.6 degrees, all oriented along southeast to northwest axes.

--- site alignments at 18 degrees ---		
site	angle	direction
Teotihuacan	18.65	s of e
	18.45	s of e
Cholula	18.48	n of w
	18.71	s of e
Tlapacoya	18.93	s of e
Cuicuilco	18.15	s of e
Tizatlan	18.66	s of e
possible dates	-- 30 degrees --	-- 23.5 degrees --
n of e or w	Apr 26, Aug 15	May 8, Aug 3
s of e or w	Feb 13, Oct 26	Jan 31, Nov 7

The "possible dates" listed above are for horizon locations of sunsets and sunrises. None of these make any sense, not even in terms of being off from some likely era-ending date by one or two days. The alignments must have had some importance, for two are coaxial and all point to the southeast or northwest.

What finally clarified these two sets of alignments was the realization that rather than representing sunsets, these two sets represented the setting of the Pleiades after a culmination in the fall of the year. I have already presented this for the city of **Teotihuacan** under a discussion in Chapter 21, as the "Day of the Dead." I suggested earlier that the commemoration of the "Day of the Dead" was likely initiated by the very influential site of **Teotihuacan**, and was codified to a calendar date (day of the seasonal year) after AD 200, when **Teotihuacan** was founded. The celebration remained located at the same (Gregorian) date of October 20th, into the Spanish era after AD 1550. With the introduction of Catholicism, it was moved to November 1st and 2nd.

Culmination of the Pleiades - Mexico City, 19.41 deg n latitude					
year	Julian	Gregorian	midnight culmination	--westerly setting-- azimuth	deg n of w
685 BC	Oct 15	Oct 8	83.5	283.3	13.3 <--
600	Oct 16	Oct 10	83.8	284.6	14.6 <--
200	Oct 17	Oct 14	86.5	285.8	15.8
100	Oct 18	Oct 16	86.2	286.7	16.7 <--
AD 100	Oct 19	Oct 18	87.3	287.1	17.1
200	Oct 20	Oct 20	87.7	288.1	18.1 <--
400	Oct 21	Oct 22	88.1	288.7	18.7 <--
700	Oct 23	Oct 27	89.5	290.7	20.7
1000	Oct 25	Oct 31	91.4	292.0	22.0
1550	Oct 30	Nov 9		294.2	24.2
2008		Nov 14		295.3	25.3

The five sites using an 18-degree alignment (for the AD 200 to 400 era) are all located in the Valley of Mexico. This represents five of the six sites I looked at. The celebration, of course, recalled the event of 2349 BC, what the Maya called the end of the "third creation" and we call the "flood of Noah." The angle north of the west cardinal direction, where the Pleiades set, only slowly moved further north. Similarly, the culmination increased its height at **Teotihuacan** until at about AD 700, when **Teotihuacan** was destroyed. At that time the Pleiades passed directly over **Teotihuacan** at midnight (for what that anecdote is worth).

If **Teotihuacan** set the celebration of the "Day of the Dead" in the period of AD 200 to AD

400, was there an earlier commemoration day, before the setting of the Pleiades on their culmination night had moved to 18.5 degrees? My first guess would be that the Olmecs at **Tres Zapotes** or **La Venta**, who had instituted the earliest era-ending markers might have done so. This seems to be correct, for by the time **Tres Zapotes** and **La Venta** were constructed, alignments are not only secured to recognize the date of April 19, 1492 BC, and February 28, 747 BC, but also to the location of the setting of the Pleiades at 13 degrees north of west, the location directly after 685 BC, marking the era-ending of 2349 BC. (And, as I will suggest below, also for an angle of 16.7 degrees, representing the setting of the Pleiades in about 100 BC.)

San Lorenzo has no such alignment. Besides the Olmec sites of **Tres Zapotes** and **La Venta**, two additional sites in the Valley of Mexico also use this alignment, **Tlatilco** and **Tlapacoya**. **Tlatilco** was apparently an Olmec outpost, and **Tlapacoya** also shows strong Olmec influences. Both are quite old, first occupied after 1500 BC. Both have alignments conformed to an axial inclination of 30 degrees. Strangely, **Tlapacoya** also has an 18-degree alignment, but not an alignment for April 19th.

... 16 to 17 degrees

The first thought would be that the alignments (for an axial inclination of 30 degrees) of 16 to 17 degrees should be combined with 15.3-degree alignments for the era-ending of April 19, 1492 BC (as Malmstrom and Aveni would have been likely to do). There are seven instances of alignments between 16 and 17 degrees, of which I have identified two as representing an alignment other than the setting of the Pleiades. The remaining five are distributed over three sites, one at **Laguna De Los Cerros** and two at **Tres Zapotes**, both in the Olmec coastal region, and two at **Tizatlan** in the Valley of Mexico. The directions of the alignments are coaxial at both **Tres Zapotes** (pointing northwest), and at **Tizatlan** (pointing southeast).

site	angle	direction
Laguna de los Cerros	16.71	n of w
Tres Zapotes	16.58	n of w
	16.43	n of w
Tizatlan	16.64	s of e
	16.36	s of e

The multiple alignments at two of the sites indicates that the alignments may have been significant. Since the alignment at **Laguna De Los Cerros** breaks the tie as to whether spring/summer or fall/winter dates should be used, I will select a spring/summer date. All three sites are quite old. **Laguna De Los Cerros** was settled between 1400 and 1200 BC; **Tres Zapotes** dates from before 1000 BC.

The solution here too, is to suggest that these alignments do not point to a date (which could be April 21) but to the setting of the Pleiades in about 100 BC. This would have been at 16.7 degrees north of west (this is marked on the chart of the Pleiades culminations above).

Tres Zapotes has alignments for February 28, 747 BC, and for July 9 and 25th, 685 BC, and additionally an alignment for a zenithal passage of the Sun on August 13th -- all conformed to a 30-degree axial inclination. Adding four alignments for the setting of the Pleiades, two for a date of 685 BC to 600 BC and two alignments for about 100 BC, salvages the unexpected lack of earlier era-ending alignments. But note that the setting of the Pleiades is conformed to a 23.5-degree axial inclination. That means it was developed after 685 BC -- in fact, probably in about 100 BC.

At **Tizatlan** there already exists an antipodal alignment for the date of April 19, 1492 BC. We can now suggest two additional alignments for 2349 BC, as the setting location of the Pleiades in about 100 BC. **Tizatlan** also has an alignment for July 14th, conformed to the era before 685 BC.

Thus the setting of the Pleiades in 100 BC is a solution to the angle of 16.7 degrees north of west. It would assume the existence of an authority, similar to the authority of **Teotihuacan** which had set the standard for the celebration of the horizon setting of the Pleiades after AD 200. This may have been **Tres Zapotes**. The dates agree with the period of activity at **Tres Zapotes**. (See the chapter "The Day of Kan.")

... a history of the culminations of the Pleiades

At this point we have a great number of instances which can be identified as marking the culmination of the Pleiades. The sequence should point to a history of the ceremonial centers. But of course old forms can be reused, and established forms can be used long after their earlier occurrence. The codification of the "Day of the Dead" by **Teotihuacan** in circa AD 200 or 400 lasted to AD 1550. So the list should be used carefully. Below the list of Pleiades

culminations is reproduced, with various sites inserted as appropriate.

-- The entry "original" can be used for all years before 685 BC.					

I should point out that September 8 was a hard and fast date before 685 BC, to mark the setting of the Pleiades at the break of day, as it had for all the time prior to this date in September of 685 BC.

Directly after the nova event of 685 BC, because the dome of the stars moved with respect to the horizon, the Pleiades culminated on October 8th. The corresponding sunset location for this date was used by four sites (with **Zempoala** using September 8th). An equal number of sites used the alternate setting location of the Pleiades after 685 BC instead of the sunset location for that day. By October the setting of the Pleiades (284 degrees azimuth) and the setting of the Sun (264 degrees azimuth) no longer corresponded.

I suspect that **La Venta** initiated this use of the setting location of the Pleiades, and **Tres Zapotes** in the Olmec area followed, followed in turn by two Valley of Mexico sites, **Tlapacoya** and **Tlatilco**.

The corrections of circa 100 BC seem to have been initiated by **Tres Zapotes**, which may have recognized the significance of this horizon direction which had already been available to **Tres Zapotes** for 600 years. It may indeed have been accepted by **Tizatlan**, but finding this horizon location at **Laguna de los Cerros** may be accidental, since **Laguna de los Cerros** has no other alignments except two suspicious looking alignments of July 14 -- two of them, coaxial, with one antipodal.

It is also obvious that after AD 200 the city of **Teotihuacan** imposes the latest correction, setting the celebration of the culmination of the Pleiades to October 20 or 22. This is

accepted by 4 other sites in the Valley of Mexico, but not in the Olmec region. October 20 remains the accepted date for the "Day of the Dead" until AD 1550, after which the Catholic Church moves it to coincide with All Souls and All Saints days in November.

Altogether with the initial sunset location representing October 8th, and with numerous changes and corrections over the course of about 900 years, there are 25 alignments celebrating 2349 BC.

Summary of Alignments

Below is a summary by the era-ending dates. I have excluded **Izapa** near Guatemala, **Edzna** in the Yucatan, and **Monte Alban** in Oaxaca, which were discussed above, but which were not tested against other local mountains. Both the Olmec sites and the Valley of Mexico sites are listed from south to north in two groups. Zenithal alignments are also listed below.

How good are these statistics? I have compared 13 sites (not counting **Izapa** and **Edzna**) with 11 mountains and found 70 coincidences (plus three questionable values), all falling within a third or a half of a degree for the dates listed above, counting alignments for a zenithal passage only once. Consider that, if there were no attempts to line up sites with significant mountains, the alignments would have been randomly distributed over 365 days. Instead, 52 of the sunset alignments fall on 6 days in two eras of differing axial inclination, thus on a total of 12 days. Twenty alignments to the setting of the Pleiades fall on three dates.

What if some of the alignments were assigned to the incorrect date? This might be suggested for alignments close to 15 degrees, which I have assigned to an April 19th date under the condition of a 30-degree axial inclination. These would then be added to the alignments for an "August 12" date under the current axial inclination of 23.5 degrees -- for a total of 11 alignments assigned to August 12th. There would still be 70 coincidences.

Alignments for various era-endings at 30- and 23.5-degree inclinations.

(2) --	two instances
(z) --	no mountain, zenithal

I found only one solstitial alignment for the current era, at **Cerro de la Mesas**. But it might be suggested, similar to the above, that any of the alignments close to 25 degrees, now assigned to July 9th (23.5 degree axis), should all represent solstitial alignments -- a total of 9 solstice alignments, all assigned to the current era. There would still be 70 coincidences.

I doubt if either of these possibilities is an error. I think what is most convincing of the reality of these alignments as era-ending markers, is the frequency of occurrence of the 1492 BC date of April 19th -- 16 instances -- and the 747 BC date of February 28th -- 10 instances. These occur first at the two oldest sites, **San Lorenzo** and **La Venta**, for the condition of an axial alignment of 30 degrees. Even more convincing, is that in addition to the four instances of alignments pointing to October 8, 2349 BC, which are listed above, an additional 20 alignments can be assigned to the setting of the Pleiades after culmination.

For every one of these 13 sites, there are 11 possible mountains to test for significant alignments. Thus there could have been as many as 11 significant alignments. But three alignments per site is the average. Five of the 11 sites use three alignments. Away from the average, two sites each use 2, 4, or 5 alignments, one uses one, one uses six. Here I am not counting alignments for the zenithal passage of the Sun, or the setting of the Pleiades.

Among the sites tested there is obviously disagreement over the date on which the most recent era ended. The changes in July of 685 BC were confusing. But the world had definitely changed. The question was, did the previous era end on July 9th, when Jupiter showed himself again, on July 14th, when he released a plasmoid, or on July 25th, when the plasmoid landed at the Sun?

There are 22 alignments which make attempts to establish a date for the era which ended or changed in 685 BC. To the possible dates which could have been used, we must add August 12, which is the equivalent calendar date of July 26th between the two eras. At any latitude within a degree or so to 19 degrees north, the sunset for August 12 when the axial inclination was 30 degrees, is within a half degree of being identical to the sunset for July 26 for an axial inclination of 23.5 degrees. This identity has no utility, however.

Each of the dates of the year 685 BC was selected an equal number of times, except that July 25th was selected 7 times, and the alignments for the dates were as readily "assigned" to the era before 685 BC of the 30-degree axial inclination, as after. Final agreement was probably reached under the hegemony of **Teotihuacan**, after 200 BC.

It is also clear that almost all sites picked either to align their important era-ending dates to an

axial inclination of 30 degrees or an axial inclination of 23.5 degrees. Only a few sites (**Cuicuilco** and **Tlapacoya**) mixed alignment for different axial conditions as convenient to the mountains or volcanoes which could be used.

La Venta stands out as an example of a site caught in the midst of the change of the axis in 685 BC, which was resolved by creating a new alignment through a reconstruction of the site. This reconstruction (and also the later massive rebuilding of **Monte Alban**) demonstrates how important these alignments were.

At this point we have a great number of instances which can be identified as marking the culmination of the Pleiades. The sequence should point to a history of the ceremonial centers. But of course older forms can be re-established, and older forms can remain in use. The codification of the "Day of the Dead" by **Teotihuacan** in circa AD 200 or 400 lasted to AD 1550. So the list should be used carefully. Earlier the list "Culminations of the Pleiades" is reproduced, with various sites inserted as appropriate.

History

The general history of the course of events seems to have run as follows: **San Lorenzo** was the first site to use both a zenithal alignment and alignments for a certain date in the past, in fact, for a date prior to the founding of **San Lorenzo** which represents, as we know from Eastern Mediterranean sources, the calendar date of the Earth shock preceding the Exodus of Moses. All the Mesoamerican sites I have looked at, with rare exceptions, also institute alignments to the horizon location of the setting Sun for this date in 1492 BC.

In the following chapter, "The Day of Kan," I will show that the tradition started at **San Lorenzo** had its genesis in similar activities in the **Soconusco** region of Guatemala at an earlier time. The tradition was one of assigning "primacy" to a single site in a region for a certain period. "Primacy" allowed the site to dispense lordship to other sites, offer the insignias of power, and provide copies of the "Books." The *Popol Vuh* has repeated references to this for the lords of the Guatemalan sites of the **Quiche**.

Primacy passed to **Tres Zapotes**, after it was terminated at **San Lorenzo** in about 900 BC, but **Tres Zapotes** was devastated by some calamity, at which time primacy passed to **La Venta**. **La Venta** was established after the Earth shock of 747 BC and the change in the length of the year. It was **La Venta** where the Long Count was initiated, and thus the book called "the Council Book."

Within a hundred years **La Venta** was caught up in the change of the Earth's axis of 685 BC. The site was rebuilt to a new central axis, aligned at a right angle for the new horizon location representing the date in 747 BC. All later sites in the region also added this alignment.

The Long Count allowed retrocalculating the date of the end of the "second creation" of 3114 BC, August 12 or 13, and the date of the end of the "third creation" (Noah's flood) of 2349 BC, as the setting location of the Pleiades. A number of sites also add the setting of the Pleiades in (after) 685 BC as an alignment, like **Tres Zapotes**, **Tlatilco**, and **Tlapacoya**. **Tres Zapotes** is Olmec, the other two sites are "Olmec influenced." **Tres Zapotes** adds this initially as October 8, like **La Venta**, reflecting a setting location for the Pleiades shortly after 685 BC, then two more alignments are added for a setting location at about 100 BC.

As a result it could be suggested that the celebration of 2349 BC was probably instituted at **La Venta** as the horizon location of the setting of the Pleiades after culmination. It should also be obvious that an interest in the event of 2349 BC was probably initiated with the return of Jupiter which was witnessed in 685 BC, duplicating the earlier return from the dead of Jupiter in 2349 BC.

The alignment for 2349 BC was adopted by other Olmec sites. The alignments previously established at **La Venta** for the dates of 1492 BC and 747 BC remained, although they were no longer valid. As mentioned above, for 747 BC a new alignment was established.

But more important, the Long Count and the "Council Books" provided a record of actual dates in 685 BC which could be claimed as significant in recording how the Sun "left its path" and returned, and how Jupiter saved the world from destruction. The dates show up as various later alignments, and are specifically referenced five times in the Maya *Chilam Balam* (most as intervals).

When the period of primacy for **La Venta** ended (in 334 BC), it passed back to **Tres Zapotes**, or may have gone elsewhere, possibly to **Monte Alban**. It was at **Monte Alban** that an ideographic script was devised which would have been used to elucidate the "Council Books" and the other books of ancient history (mentioned in the *Popol Vuh*) which in turn allowed access to the information by other tribes.

In AD 224 primacy passed to **Teotihuacan** which held it until circa AD 700. **Teotihuacan** was enormously influential, and spread its doctrines (concerning alignments) into all of the Valley of Mexico, back into the Olmec coastal region and the Yucatan Maya region, as at **Edzna**.

Teotihuacan redefined the celebration of the "Day of the Dead" to the then current horizon location of the setting of the Pleiades in AD 200 or 400. This date remained in use into the Spanish era, 1200 years later. From **Monte Alban** and **Teotihuacan** the information of the past was promulgated to other tribes, so that there was a choice of what significant alignments could be used for any location.

I'll provide additional historic details, as it can be gleaned from alignments and sculptures, in the chapter "The Day of Kan."

Endnotes

Note 1 --

The single solstitial alignment in the current era was for **Cerro De La Mesas** (24.90 degrees n of e, antipodal). I also found two suspected solstitial sunsets for the previous era, **Remojadas** (31.92 degrees n of w) and **Cholula** (31.94 degrees n of w).

At **Cerro De La Mesas** all 5 other alignments are for the previous era. At **Remojadas** all 5 other alignments are for the current era. At **Cholula** six other alignments are for the current era. Since none of these solstitial alignments match the era for the other and more frequent alignments of these sites, I feel safe to dismiss all of them.

[\[return to text\]](#)

Note 2 --

We cannot speak to most of the religious practices of Mesoamerica which first show up in Olmec times, in 1500 BC to 400 BC, for we do not know what they involved. However, we can penetrate some of the symbols left behind. The cloud altars, the giant stone heads, the jaguar images, and the jaguar babies can all be explained in reference to celestial planetary phenomena. Close passes of Mars in the 8th century BC would have brought hurricane winds and tides to the neck of Mexico where the land is less than 150 miles (240 km) between two oceans. Giant continuous lightning bolts were also experienced, although much further north. Mars was perhaps represented by the bat-image Jaguar, and a source of supreme terror. After 800 BC, I would expect that Mercury was the "Jaguar Baby."

However, a "presentation" scene of a were-jaguar infant spread on the lap of an adult is seen also at **San Lorenzo**, carved into an altar, and thus probably dating to before 900 BC. As such, the "Jaguar Baby" might represent an earlier appearance of Mercury and Mars starting in about 1935 BC.

[\[return to text\]](#)

Note 3 --

The inclination of the Earth's polar axis (with respect to the normal of the orbital plane) shifted from 30 degrees to 23.5 degrees in 685 BC.

Names of Katuns in the rotating 13 Katun series are named after the last day of the Katun. For the Katun ending after 685 BC (astronomical, Gregorian) this is 3-Ahau (6.4.0.0.0).

[\[return to text\]](#)

Note 4 --

The actual calculation finds the difference in Gregorian calendar days for 14 Tzolkin periods.

This is 12.4 days, and matches the change in the Gregorian calendar for a setting sun of a zenithal passage for the latitude of **Monte Alban** or **La Venta**.

[\[return to text\]](#)

Note 5 --

The rising or setting Sun moves only by small increments along the horizon from day to day as the summer (or winter) solstice is neared. With the passage of each day before the solstice the Sun rises at a lesser fraction of a degree north of east. It takes 16 days to move the last degree. This much movement would, however, have been noticed, for the Sun would have moved two Sun diameters. I think eyeball sightings can be much closer than two degrees. A finger held at arm's length subtends one degree, which is twice the width of the Sun.

The reason for selecting alignments was religious and not intended as a demonstration of priestly skills at geometry or its use as the basis for calendar recalculation. But the measurements are in fact very close -- often within a quarter of a degree, and seldom as far off as a third of a degree. We know that the calendar was never ever recalculated. The sloppiness allowed by Malmstrom contradicts his suggestion that the alignments were needed for calendar calibration.

It might be suggested that Malmstrom meant that stepping away from the center of a ceremonial center would not move the sunset location by more than 2 degrees. This might be true for the Maya ceremonial center which used sightlines to nearby structures, but for Olmec ceremonial centers, which were located many miles from the target mountains, this could not be true. Consider stepping sideways by 20 feet from the sightline to a mountain which was located 20 miles away. The angle of view would not change by more than 1/100th of a degree, $\arctangent(20 / (20 * 5280)) = .010 \text{ degrees}$. The mountains used for alignments were often 100 to 200 miles away. One would have to move a mile away from the center of the ceremonial center to reach a mismatch of a half degree if the mountain were 100 miles away.

In *Cycles of the Sun, Mysteries of the Moon* (1997), Malmstrom remarks on the observations of Venus in Mesoamerican Maya and Mexican records, and notes that it is easier if the Mesoamerican (Tzolkin) calendar is used. He records the periodic rising of Venus out of the volcano Orizaba (Citlaltepetl) east of **Cholula** in about AD 830 to AD 1454 (the period of investigation by Malmstrom).

In a later paper, "The Role of Venus in Mesoamerican Calendrical Origins" (nd) (at <http://www.dartmouth.edu/~izapa/Venus.html>), Malmstrom argues for a start of the Tzolkin calendar in 1359 BC at **Izapa**, coinciding with a heliacal rising of Venus "over Volcan Tajumulco" at 66 degrees, 35 minutes azimuth (23.4 degrees north of east). He also suggests that the 365-day Haab calendar came into existence a few decades later at **Izapa**, with the heliacal rising of Venus in 1324 BC, at 22.41 north of east, "nearly over Tajumulco."

Let me point out that this rising of Venus "over" or "nearly over" Volcan Tajumulco is off by 7 degrees -- nearly two hand-spans at arm's-length. That is not "nearly." Additionally, the skies and the year were radically different in 1359 BC (although Malmstrom would not know this), so that retrocalculations using today's parameters will not yield sensible results.

I have already established that the Tzolkin originated in its present form on September 6, 2349 BC (Gregorian equivalent). The original Haab (360 days) dates from April 19, 1492 BC (Gregorian equivalent), and the modified Haab (365 days) dates from February 28, 747 BC, as has been detailed in a previous chapter.

[\[return to text\]](#)

Note 6 --

There are some considerations with respect to the inclination of the Earth's axis (discussed in Appendix "Change in the Axis") which might affect this data, although mostly the impact remains the same.

[\[return to text\]](#)

Note 7 --

I originally assigned the angle of 6.6 degrees to April 2, but it was not supported by anything except the possibility that perhaps the blazing of Venus started on this date. It also does not fit the Mesoamerican notion of celebrating the concluding date of events, and not the starting date.

Since any angle above or below the east-west axis can generate four calendar dates, the next guess was September 8th. This made much more sense, because it would reflect the second day after the fall equinox. The equinox before 685 BC fell on September 6th. Since September 8th was the night when Jupiter had returned from the dead, and the Pleiades would reach culmination, it was a short reach to suggest that this was probably the commemoration of the closing date of the "third creation" in 2349 BC -- the celebration of the "Day of the Dead".

This also solved the problem of why there were otherwise very few *sunset* alignments for this date. After 685 BC the culmination of the Pleiades, as a celebration of the return of Jupiter from the dead, immediately moved to October 8 (September 21 plus 2 days plus 15 days), and then started to drift further into the fall season with the precession of the equinoxes, which had started in 747 BC. Almost everywhere in the world, it is the culmination of the Pleiades at midnight which marks the "Day of the Dead," not a calendar date.

Thus the reason there were few alignments corresponding to a sunset for a date of September 8th (before 685 BC) or October 8 (after 685 BC) is due to the fact that the sites changed to marking a setting of the Pleiades rather than a setting of the Sun -- at some sites for the date of October 8th, representing the setting location directly after 685 BC, and at other sites for

the date of October 21 or 22, representing the setting location in about AD 200 to 400. This accounts for 15 "2349 BC" alignments among 9 of the 15 sites. The calendar date of October 21 or 22 was apparently set by **Teotihuacan**, and was still in use 1300 years later when Cortez met up with the Aztecs.

There are also five sunset alignments (rather than the setting of the Pleiades) for September 8th to signal the culmination of the Pleiades before 685 BC.

[\[return to text\]](#)

Note 8 --

Anthony Aveni, in *Skywatchers of Ancient Mexico* (1980), assigns the invention of the 260-day Tzolkin to the site of **Copan**, located at a 14.85 degrees north (similar to the latitude of **Izapa**), where the Sun overpasses the site on August 13, and again 260 days later on April 30. **Copan** as the source of the Tzolkin seems even more unlikely than **Izapa**.

[\[return to text\]](#)

Note 9 --

A look at a table of latitudes and zenithal dates, reproduced in the 1979 book by Malmstrom, has August 13 missing. Yet this is followed immediately with the statement "*The zenithal sun makes its southward passage over latitude 14.8 N on August 13.*"

Latitude [degrees]	Southward	Northward	Days Elapsed	
			N-S	S-N
-----	-----	-----	---	---
13.5	August 17	April 26	113	252
14	August 15	April 27	110	255
14.5	August 14	April 29	107	258
15	August 12	May 1	103	262
15.5	August 10	May 2	100	265

Using my Qbasic program, I get the following values:

Latitude [degrees]	Day of zenithal	Elevation of the Sun	
-----	-----	-----	
14.5	August 15	89.24 degrees	
14.5	* August 14	89.56	
14.5	August 13	89.89	<---
15	August 13	89.39	
15	* August 12	89.71	
15	August 11	89.97	<---
15.5	August 11	89.52	
15.5	* August 10	89.83	
15.5	August 9	89.86	<---

* -- Malmstrom's table values (1976)
<--- day of zenithal overpassing

As can be seen from the above, my calculations for each of the three latitudes are late by a day. Thus, although I assign "August 11" to Izapa, it may be August 12. But it is not August 13.

I am using a latitude of 14.90 degrees north (established by others and published). By comparison, Malmstrom uses a latitude of 14.8 degrees. This inches the overpassage close to August 12, but not August 13. The difference between 14.9 and 14.8 degrees of latitude represents a difference of about 7 miles (11 km). The site, which is spread over a long swatch of land running from SSW to NNE, is only 1.4 miles (2.25 km) in length.

I get the following for the zenithal angle of the Sun on various dates using 14.9 degrees latitude, compared to Malmstrom's use of 14.8 degrees latitude:

Zenithal passage of the Sun at Izapa (14.90 degrees latitude)	
date	angle above horizon
-----	-----
August 13	89.49 degrees
August 12	89.80 degrees
August 11	89.87 degrees <----
Zenithal passage of the Sun at Izapa (14.8 degrees latitude - Malmstrom)	
date	angle above horizon
-----	-----
August 13	89.50 degrees
August 12	89.90 degrees <----
August 11	89.77 degrees

Use of a latitude of 14.4 degrees north would have guaranteed the date of August 13, with the Sun reaching 89.99 degrees above the horizon. But that is a location 39 miles (63 km) further south.

[\[return to text\]](#)

Note 10 --

I have noted in previous text that the surpluses of maize from a single farming family could feed 20 additional people for a year. These surpluses were put to use to build, expand, and maintain ceremonial centers. It is a process which could have easily expanded from the communal support of a single shaman (or "day-keeper," as they are called today).

The growth of ceremonial centers was voluntarily supported by the population, for the benefits were visible and obvious. Of greatest benefit would be the fact that the surpluses, which would normally be used for a labor force and trade contacts benefitting the ceremonial center, could be used to sustain the citizens through years where unexpected frost or lack of (or excess) rains would have destroyed crops and caused a famine which an individual family would not have been able to endure.

The agricultural surpluses are also key to understanding the abandonment of sites. If a drought or other adverse climatic conditions lasted three years or more, a farming family would move away to find a better environment, for the support from a ceremonial center could not be extended indefinitely. With the severe social strictures in Mesoamerica against the accumulation of wealth, a relocated farmer would also have cut down his planting to just cover the needs of his immediate family.

The same results would be seen if the shamans, for whatever religious reasons, abandoned a ceremonial center. The farmers who remained behind would also cut back maize production, both for social reasons and because no one wants to do unneeded farming.

[\[return to text\]](#)

Note 11 --

When I use the phrase "Gregorian equivalent," it should be realized that for years before 747 BC this represents spreading the 365.24 days of our current Gregorian calendar over 360 actual seasonal days, and without allowances for leap days.

[\[return to text\]](#)

Note 12 --

There are 44 volcanoes in Mexico, 40 of them on the mainland. The list of mountains and volcanoes, which I have used to check alignments in the Valley of Mexico and the Veracruz region, have excluded volcanoes north or west of **Paricutin Cono** (19.46 n, 102.2 w).

[\[return to text\]](#)

Note 13 --

Alfred de Grazia, in *The Lately Tortured Earth* (1983) writes:

"One perplexed writer suggested that the Mesoamerican Olmecs aligned their structures with the Big Dipper. When neither the north-south axis nor the solar behavior nor a constellation fits the orientation, then it is that the ancients could not tell directions well, or that the matter in any case was not important to the builders."

"What is absent from such reasoning? First, there is a failure to appreciate that the desire to orient to the skies was an obsession, a compulsion, an inescapable tradition, a sacred obligation, a proud duty. Second, the ancients, as far back as we can discover their humanity, could calculate readily and exactly the course of heavenly bodies and orient themselves thereto. Many examples of this are presented in de Santillana and von Dechend's book, Hamlet's Mill."

[\[return to text\]](#)

Note 14 --

The zenithal sunrise of August 14 (18.93 degrees s of e) for before 685 BC, could also be used to point to the era ending date for 3114 BC (19.36 degrees n of w). But I doubt if that was so. Although the ending (day 13.0.0.0.0) of the previous era could be found by retrocalculation, the fact that it would represent August 13 of 3114 BC (4-Ahau 8-Cumku), suggests that a 365.24-day year would have been used. It is an unlikely mistake to be made directly after 747 BC, when the Olmecs certainly would have known that the year previously was 360 days, not 365.24 days.

[\[return to text\]](#)

Note 15 --

Aveni also claims the Pleiades would have risen heliacally on the first day of the zenithal passage of the Sun, which would be May 17 (the second passage is July 25). Aveni has May 18th.

But for **Mexico City** in AD 150, on May 17, the day the Sun passes overhead, the Pleiades stand at an altitude of 19.5 degrees above the horizon as the Sun rises. They do not rise with the Sun (that is, heliacally), as Aveni claims. I have April 22 for the heliacal appearance of the Pleiades.

I used the location of the Pleiades for **Mexico City**. This can be done because the difference in latitude between **Mexico City** and **Teotihuacan** is 0.267 degrees, resulting in a change in the setting location of the Pleiades along the horizon of only 0.26 degrees.

Aveni's book contains a lot of erroneous data, including calendar dates and horizon azimuthal measurements. For my purposes, an alignment which is off by one degree is totally unacceptable. As noted, I am generally holding alignments to 0.3 degree.

[\[return to text\]](#)

Note 16 --

Malmstrom also writes,

*"Peterson also notes that the side walls of one of the oldest structures at **Monte Alban**, Mound K, are oriented to the sunrise positions on March 9 and October 5, which he suggests reflects the Zapotecs' method of defining a 52-day interval before and after the zenithal sun passages at **Izapa**."*

I think this has nothing to do with **Izapa**. It is just unlikely that a location of such importance and independence as **Monte Alban** would have anything to do symbolically with the remote site of **Izapa**. The "52-day interval before and after the Izapa zenithal" is 53 days after August 13 (for October 5), and is 51 days before April 30 (for March 9). Because I have not seen these dates in use elsewhere, I cannot attach any significance to them. It is possible that they show up in the Peten, where **Monte Alban** might have had a larger influence.

[\[return to text\]](#)

Note 17 --

Anthoni Aveni, in *Skywatchers of Ancient Mexico* (1980), mentions (from the research of others) that a staircase of Building J aligned with Capella in about 250 BC, but notes that Capella's heliacal rising would have coincided with the date of the zenithal passage of the Sun.

Alfred de Grazia, in *The Lately Tortured Earth* (1983), references Anthony Aveni, in *Archaeoastronomy in Pre-Columbian America* (1975), as claiming that many sites in Mesoamerica are oriented about 17 degrees east of north, mostly in the Valley of Mexico. He includes **Teotihuacan**, **Cholula**, and **Tula** and some buildings at **Chichen Itza** in the Yucatan. But the axis of **Teotihuacan** is oriented at 15.5 degrees east of north, not 17. Aveni also claims that the site orientation of 50 out of 56 sites he investigated (including Peten sites) were aligned east of north, and claims that Olmec sites are oriented 7 or 12 degrees west of north. None of this makes much sense, and most of it is dead wrong. This is discussed further in an endnote to the chapter "The Day of Kan."

[Image: Big Horn Medicine Wheel, Wyoming; looking west. USDA Forest Service.]

Similarly the markers outside of the circle of the Big Horn Medicine Wheel in Wyoming are assigned by Aveni (1975) to the summer and winter solstice, plus the rising of the stars Rigel,

Sirius, and Aldebaran. We can be sure that these exterior markers were placed in more recent times. But a count of the number of lines radiating from the center of the wheel reveals 28 spokes, which places its original construction to before 3147 BC. The exterior marker which is removed away from the circle is today aligned with the summer solstice, but would also have pointed to the contact with Saturn in the North Atlantic.

Some of the alignments determined by archaeologists seem far-fetched in that some are taken across the center marker, and some across two exterior markers, sometimes through the centers, at other times along the edges. I am reminded of Gerald Hawkins, who, in *Stonehenge Decoded* (1965), found 165 alignments at Stonehenge with the rising and setting of the Sun, Moon, and various stars. See also Martin Doutre's analysis of a mass of stones at Waitapu in New Zealand, at <http://www.celticnz.co.nz> (a local copy at othergroup.net/waitapu.php), a spoof which will move the science of ancient alignments far into the future.

Finding the Day of Kan

I have to add a **warning**: This will be an arcane and difficult chapter, for here I will attempt to trace a 3000-year history of the Mesoamerican ceremonial centers, starting in Guatemala at about 2400 BC. You may want to skip this chapter since it primarily deals with efforts of the Olmecs to trace the past history of important events through the application of the Long Count.

And just as the Olmecs managed to validate their findings, which consisted of locations of the setting Sun along the horizon, (and thus represented anniversary dates of events), so can we, by taking a slightly wider view, reconstruct a history of the primacy of leading ceremonial centers over a span of time possibly starting in 2400 BC. This will reveal the use for the collections of giant stone heads and altars in the Veracruz regions, and the "fat boy" sculptures found in Guatemala.

This chapter therefore continues the investigation into the Mesoamerican site alignments started in the previous chapter. With the previous chapter my main purpose was to check site alignments to mountains and volcanoes among early Olmec sites and locations in the Valley of Mexico. The data showed conclusively that the change in the inclination of the Earth's axis could be verified from site alignments before and after 685 BC, and revealed anniversary dates for every important event of the remote past.

What I will do in the following is to provide a basis for what looks like region-wide concerns about these dates in antiquity which were "determined" by the Olmecs and the people of the Valley of Mexico, with special attention to **Monte Alban**. Additionally I will attempt to integrate the large sculptures (like the massive heads and altars) into the brief outline of history provided at the end of the previous chapter.

Two things stand out, first the notion that new re-creations of Earth fell on the "Day of Kan," and secondly that this happened in a Katun 9-Ahau. Both of these ideas apparently dated from remote antiquity, from the time of the end of the "third creation" in 2349 BC (which I will detail below), and were verified (so to speak) by data of other catastrophic events of the past.

After the Long Count was established, whatever wasn't known about the past could be found through retrocalculation. And it looks like that this may certainly have been done for the end of the "second creation" of 3147 BC, which, however, calculated to 3114 BC. The calendar day on which the world had been recreated was calculated to be August 12.

Teotihuacan (200 BC to AD 700) celebrated both July 25 in the solar year and August 12. This giant city is the primary example of the August 12 alignment achieved architecturally. The city was built on a rectangular grid, with the main avenue aligned 15.5 degrees east of north.

At the center of the main avenue of **Teotihuacan** (called "the Street of the Dead" by the Aztecs) is the giant Pyramid of the Sun (also appropriately named by the Aztecs). The Sun sets directly opposite the Pyramid of the Sun, that is, at a right angle to the Street of the Dead, on August 12. August 12 is the result of a retrocalculation which assumes that the solar year consisted of 365.24 days, not 360 days, as the Olmecs had known in 747 BC. Vincent H. Malmstrom suggests that the date of August 13 (the following day) celebrated the birth of the "creation" of the world in 3114 BC (the end of the "second creation").

The "Day of Kan," was New Year's Day among the later Maya, celebrated on July 26th, and noted by Landa in the 16th century AD, when July 26th actually coincided with a "Day of Kan" on the Tzolkin calendar. But the "Day of Kan" only fell on this day every other decade (at twenty-year intervals). The "Day of Kan" is as much a generic name for the New Year Day, as it is an actual Tzolkin calendar day. "Kan" means maize (as well as "snake" and "sky"). I suspect that, well before 685 BC, the "Day of Kan" was already established as the day a previous creation had been renewed.

After 685 BC, attempts must also have been made to again rationalize the start of the current creation to a "Day of Kan." The rationalization involved the simple suggestion that a day named Kan had fallen 12 days earlier, that is, it fell on July 14, Gregorian, 685 BC (the release of the plasmoid from Jupiter), which is 6.3.4.5.4 17-Chen 2-Kan on the August 13 Long Count (not on the August 11 Long Count).

This concern with the "Day of Kan" was perhaps misapplied science by the Olmecs, but it seems to have taken hold, for I suspect that the massive remodeling of the **Monte Alban** ceremonial center in circa 275 BC, which seems to have revolved around an alignment correction of 12 days, might have been one of the results stemming from this concept. Additionally, the Olmecs and the people of the Valley of Mexico start to align many of the ceremonial sites to the day of July 14th (12 days before July 25). This suggests that

something significant had happened on that day. [\[note 1\]](#)

Of course, I am approaching conjecture here. But if I may be allowed to continue (and the following is not conjecture), I would suggest that the Olmecs kept daybooks, like the Babylonians, Egyptians, and other literate people. They could look up the records of the past. The documents of the ceremonial centers in the Valley of Mexico were only destroyed when the Aztecs arrived. The Maya records survived until the Spanish arrived. Only a last-minute transcription to the *Books of the Chilam Balam* has saved, for our benefit, a summary record of the past, dating back thousands of years. The *Chilam Balam* frequently makes casual references to actual dates and time intervals, indicating details which must have existed in the source documents. The *Chilam Balam*, in fact, provides five specific dates (as time intervals) for the summer of the year 685 BC.

What might have happened 12 days before July 25th when the plasmoid bolt of Jupiter ended an era? What comes to mind, of course, is that the plasmoid lightning bolt must have taken some time to travel 484 million miles. The solar wind leaving the Sun travels past the Earth at about 2 million miles per hour. It apparently does not speed up significantly after passing Earth. If a bolt traveling from Jupiter also averaged that speed, it would take 10 days to cross the 5.2 AU distance to the Sun. The Olmecs, by selecting the primacy of the "Day of Kan," for July 14th, in effect are suggesting it took 12 days.

Jupiter probably expanded its coma weeks before the return stroke was released. The specifics of the illustrations which were developed by the Olmecs, and which eventually became the religious iconography of the Maya, would require that Jupiter was clearly seen and recorded for a reasonably long period. From other alignments adopted after 685 BC, it would look like the date of the initial expanded coma was July 9th. The *Chilam Balam* seems to fully concur in this selection.

At **Monte Alban** the rationalization of the Tzolkin calendar involved restarting the Tzolkin annually on August 14th. The fourth day of the Tzolkin, 4-Kan, would then fall on August 17th, the day when the Sun had passed overhead of **Monte Alban** in the era before 685 BC, when the Earth's axis was still at an inclination of 30 degrees. And the "Day of Kan," everyone knew, had started the current era, as it apparently had started every change in the constitution of the heavens, or so it was thought.

After 600 BC the August 12 alignment was adopted at many locations -- but so were the three dates in July of 685 BC, and equally the date of September 8, which indicated the end of the "third creation" and constituted the completion of the previous world order. The dates of 1492 BC and 747 BC were known.

The date of the end of the "third creation" (2349 BC) was selected on the basis that it involved a culmination of the Pleiades. Before 685 BC, that happened on September 8th, two days after the fall equinox of September 6th (15 days earlier than today). Directly after the summer of 685 BC, when the dome of the stars had rotated 15 degrees, the culmination

occurred on about October 8th, and then started to drift later into the year with the precession of the equinox.

A sunset location, corresponding to the culmination of the Pleiades, was first celebrated, correctly, as October 8th. Four sites use a setting location of October 8th as an alignment. A fifth site uses September 8th as the date of the culmination of the Pleiades -- information correctly gleaned from the Council Books and valid for the era before 685 BC.

The new culmination of the Pleiades was October 8th, with the Pleiades setting at 13.3 degrees north of west.

This 13.3 degrees north of west was adopted as a horizon alignment by four sites. Three later sites made corrections in about AD 100 to October 16th (at 16.7 degrees north of west), and then in about AD 400, **Teotihuacan** redefined the new setting location of the culmination of the Pleiades for the date of October 22 (at 18.7 degrees north of west). This was adopted by five sites in the Valley of Mexico, and remained in use for the next 1200 years without further corrections. I should also point out again that each sunset alignment and each of the setting location for the Pleiades was fitted to a mountain or volcano.

The "Day of Kan" for 2349 BC

But what about the "Day of Kan"? I think the obsession of Mesoamerica with the "Day of Kan" can be related directly to the cataclysmic event of 2349 BC, the end of the "third creation," the fall of the Absu, the flood of Noah. From this, and from retrocalculations of the event of 1492 BC, it may have been obvious that any era had to end on the "Day of Kan." Two data points define an infinite set of curves, but for humans the coincidence typically is overwhelming evidence that an established relationship exists.

The *Chilam Balam* relates the "Day of Kan" to the time of the "second baptism," that is, the flood of Noah in 2349 BC. Much later recollections of the Maya of the Yucatan recall a flood which separated two eras. It is also referred to in both the *Popol Vuh* and the *Madrid Codex*. But the *Chilam Balam* is the most specific, assigning it to a Katun 9-Ahau, which can be placed to the Long Count date of 2.2.0.0.4 2-Kan on the August 11 correlation, although the year is incorrect. The year was retrocalculated to fit a July 26th horizon location. It is, in fact, as I have pointed out earlier, the only instance in the whole of the 5200-year Long Count calendar when the "Day of Kan" actually did fall on July 26th.

What probably came down from remote antiquity, well before 1492 BC, was information about the end of the "third creation," the event of 2349 BC, what we know as "the flood of Noah." This had been the second "flood" and was a major marker in the histories of people throughout the world. The Israelites understood it as "the flood of Noah." China starts its history at this point. I have detailed this in chapter 20 and 21. For the Olmecs, one creation had ended and another one had started up, on the "Day of Kan."

But now consider the following: It is very possible that a Katun 9-Ahau had actually started at the time of the end of the "third creation" in 2349 BC, on the day of the fall equinox, September 6. In which case the fourth day (New Year's Day) would be a "Day of Kan." A separate page of the *Chilam Balam* reads, about the event of 2349 BC:

"And then days of the year were introduced."

It was this event which changed the length of the year from 240 days to 260 days. The 260-day Tzolkin was introduced, on September 6, 2349 BC, using a rotation of 13 days to follow the waxing and waning of the Moon (a coincidence or determined much later) and forming 260 separately named and numbered days to fill the year. It is difficult to imagine how soon this calendar was devised. But once established, the fourth day of the new calendar would celebrate the end of the third creation, and nearly 2000 years later would have become New Year's Day -- and the "Day of Kan," for as always, the fourth day of a Tzolkin calendar rotation is the day named Kan.

It is thus very likely that this "Day of Kan" -- September 9, 2349 BC -- was the fourth day of a Katun named 9-Ahau. That also means that, as had (supposedly) happened in 3147 BC, the previous Katun would have been named 11-Ahau -- the Katun which always represented all of prehistory. This coincidence of ending an era with a Katun 11-Ahau would again be validated in 747 BC, when the same sequence of events would take place.

That was probably as much as was known from the records of the past in 747 BC, when the Long Count was developed, along with the common knowledge that the first day of the new era was the "Day of Kan" and that the previous night had been marked by the culmination of the Pleiades. With the introduction of the Long Count, the Olmecs would, within a hundred years, have been making inquiries into the events of the past. These studies might have started well after 747 BC, however, for the results forthcoming from the inquiries make sense only if the Long Count and the Tzolkin calendar are used with the assumption of a 365.24-day year, not if based on shorter years before 747 BC. [\[note 2\]](#)

The Olmecs did not count in days before 747 BC, they counted and kept records in solar years called "Tuns," and in 20-year periods called "Katuns." It did not matter if the year in previous ages had been 260, 273, or 360 days long. A Tun was a Tun, and the difference between the solar year of 2349 BC and the year 747 BC was 1602 Tuns. The time of the flood, what the *Chilam Balam* called "the second Baptism," was thus 4 Baktuns (4 measures of 400 Tuns) and 2 years in the past from 6.0.0.0.0, February 28, 747 BC. The event could be placed in 1.19.18.0.0. The "Day of Kan" would be 1.19.18.0.4, always the fourth day of a Tun.

Using years of 365.24 days, the above event of 1.19.18.0.4 would fall in 2327 BC. Additionally, the day should have been September 8th, as we know from the same Mesoamerican sources. But the 2327 BC date falls erroneously on March 2. The second flood had nothing to do with July 26th. Yet this confusion existed.

Here is what was most likely done by the Maya (perhaps during the Classical Era): There was no "Day of Kan" to match a horizon location of July 26th during Baktun 1 Katun 19 Tun 18 (1.19.18.0.4). The solution was to take a cue from the knowledge that the event "must have happened" in a Katun 9-Ahau. And, as it turns out, in the following Katun 9-Ahau, on the day of 2.2.0.0.4, the "Day of Kan" fell on July 26th. This would not happen again in all of time, or at least until well after the present series of Katuns would turn over and restart in AD 2012. The records of the past were changed accordingly, although the new date missed the flood of 2349 BC by 83 years, and the calendar date missed it by more than a month. The *Chilam Balam* reports on the newly determined date as if it was fact. It is the only (obvious) error in dating in Book 10 of the *Chilam Balam*. [\[note 3\]](#)

And here is what most likely actually happened: First, the Tzolkin calendar was started in 2349 BC, in fact it probably started with the day the plasmoid from Venus arrived, September 6, 2349 BC. Another, separate page of the *Chilam Balam*, dealing only with the end of the "third creation," states that "then days of the year were introduced." We can be sure that the people of Mesoamerica had been counting in "Tun" years since long before 10,900 BC. It is also obvious (or at least, to me) that after 3147 BC a 240-day calendar consisting of 12 rotations of 20 named days was in use. China's original calendar uses a very similar rotation of 12 against 10.

With the calamity of 2349 BC (and the first appearance of the Moon) an accounting of numbered days was added -- "days of the year were introduced." Thus, to the established calendar of 20 named days, a count of 13 numbers was added, representing a half period of the Moon. This resulted in 260 uniquely named and numbered days. The length of the year had just changed to 260 days. This is the Tzolkin, which fitted the year exactly.

The 240-day calendar would have been 20 days shorter than the 260-day calendar. But this notion does not help in relocating the 2349 BC "Day of the Dead" so that we would end up with Katun 9-Ahau.

The Tzolkin that we are familiar with must have started on September 6, 2349 BC. On the third day of the new calendar Jupiter returned from the dead. By this time the smaller plasmoids from Venus had passed, and the turmoil in the sky might have subsided. Thus the third day (September 8th) actually marked the end of the "third creation," and the next day would be "New Year's Day" of the renewed creation of the world. This fourth day was the "Day of Kan," as it always is for the first Tun of a new Katun.

The fact that a Katun and Tun had just started on September 6 (the fall equinox before 685 BC) may be coincidence or it may be purposeful. It can be suggested that a new year normally started at the fall equinox. Since the previous calendar of 240 days rotated through the 20 day names 12 times, a new year would always start on day-name Imix. The fourth day would be Kan.

Since the Olmecs already had a year-count of Katuns (20-year periods) and Baktuns (400-

year periods) in use, it is possible that this was actually the start of a Katun 9-Ahau. Otherwise the notion that the "third creation" started in a Katun 9-Ahau might have followed from what had happened in 747 BC, when the Long Count was started at the beginning of a Katun 9-Ahau.

The "Day of Kan" for 1492 BC

I thought initially that perhaps I could just roll back the Tzolkin calendar from February 28th, 747 BC, compensating for the fact that the year was of a different length, and do a search for when in the remote past -- somewhere around 1492 BC -- a Gregorian equivalent day of April 19th would have coincided with a day named "Kan." But this yielded no sensible results. I subsequently considered that perhaps the Olmecs or the people of the Valley of Mexico might already have made the calculations using the Tzolkin and a record of events from antiquity.

I thus checked the Gregorian date of April 19, 1493 BC (-1492 in astronomical nomenclature). It turns out to fall on 4.2.4.5.4 6-Kan (August 11 correlation). The day of April 19 will not again fall on the "Day of Kan" for 22 years before or 25 years after 1492 BC.

Those applying the Long Count obviously had forgotten that the year had lengthened in 747 BC and the retrocalculations were performed as if the solar year had always been 365.24 days long. This would suggest that the retrocalculations for 1492 BC were made sometime after 685 BC.

Note that, as with the date of July 26th, 2349 BC, above, this works out on the August 11 correlation, not the August 13 correlation. The "Day of Kan" of 1492 BC was derived by use of the original Long Count. It also suggests that the notion of a "Day of Kan" came from much older sources. This can be seen, as I have shown, also from the 1492 BC alignments which show up at the oldest site, **San Lorenzo**. [\[note 4\]](#)

The Remodeling of Monte Alban

Consider how important "era-ending" dates were for the Zapotecs, who in about 275 BC made the investment of remodeling **Monte Alban** by completely leveling off a mountain top and reconstructing all the buildings (except one) to face a different direction, so that the end of an era could be pointed to. The "Day of Kan" was held as a sacred truth; it was the name of the day each era had ended or started. [\[note 5\]](#)

Of course, the remodeling of **Monte Alban** does not prove that by 275 BC the 360-day year had already been forgotten. Nor does the introduction by the Zapotecs of an annual version of the Tzolkin calendar, restarting each year on August 14th, so that the 4th day, 4-Kan, would fall on the Gregorian equivalent day when, 400 years earlier (as well as in 275 BC), the Sun

had passed directly overhead at **Monte Alban** on August 17th. But being able to use the day number and a day name of Kan to coincide with a zenithal Sun at their sacred location was important enough to the Zapotecs to break faith with all the other tribes in Mesoamerica and refashion the sacred Tzolkin to their own needs. No other tribe ever did that. More on this further below.

The "Day of Kan" for 747 BC

Working backwards with the Long Count notation, no "Day of Kan" can be found at 6.0.0.0.0 for 747 BC, except that a "Day of Kan" follows four days later (6.0.0.0.4) as it always does at the beginning of a Katun. What the event of 747 supplied was the start of an era in a Katun 9-Ahau. It should be noted that the *Chilam Balam* also places the events which follow directly after 3114 BC (or 3147 BC) in a Katun 9-Ahau -- despite the fact that the Long Count date of 0.0.0.0.0 (when retrocalculated on the basis of a 365.24-day year) starts a Katun 4-Ahau.

Although there was no clear "Day of Kan" for 747 BC, the era-ending was celebrated with alignments to volcanoes and mountains at **La Venta, Tres Zapotes, Cerro de la Mesas, Remojades, Zempoala, Tlatilco, Cuicuilco, and Tlapacoya** -- 8 of the 13 sites I investigated.

The Earth shock of 747 BC was not understood to be the end of a creation. The destructive close passes of Mars continued for another 60 years (as they also had preceded 747 BC by 60 years). There is virtually no mention of this event in the *Chilam Balam* and none in the *Popol Vuh*. Instead, it was the events of 685 BC which are brought forward as the relief from an impending end of creation -- or as an extension of creation.

The "Day of Kan" for 3114 BC

For 3114 BC no actual "Day of Kan" can be found. (I have to use 3114 BC here, rather than 3147 BC.) Of course the fourth day of the new era, 13.0.0.0.4, is 4-Kan.

The suggestion by Vincent Malmstrom is that the various and frequent site orientations of 15.5 degrees north of west all represent the celebration of the start of the current epoch, on August 13, 3114 BC. In an article written in 1981 Malmstrom lists some 20 sites with axial alignments at 15.5 degrees north of west and thus pointing to a sunset on August 12. [\[note 6\]](#)

Of the 13 sites I investigated, 8 have alignments reflecting some aspect of the August 12 or 13 date: **La Venta, Tres Zapotes, Cerro de la Mesas, Teotihuacan, Tlatilco, Tizatlan, Cuicuilco, and Tlapacoya**. At **Tres Zapotes**, which may have preceded **La Venta**, the zenithal sun passes over the site on August 13 before 685 BC.

At **La Venta** there are two alignments representing April 19 (15.22 and 15.32 degrees north of west) before 685 BC. These were not corrected after 685 BC, but likely became the

markers for an August 12 sunset. It is also possible (but unlikely) that the zenithal passage of the sun on August 14, before 685 BC, reflected in sunsets at 19.35 degrees (n of w) and 19.50 degrees (s of w), might have been meant to represent the date of August 13, but as the day after (thus a New Year's Day).

Only at **Tres Zapotes** or at **La Venta** could the calculations have been made, after the institution of the Long Count, to find the day of the "second creation." To find the August 13 date, shortly after 747 BC, as was certainly done at **Tres Zapotes**, is rather stunning. First, because it assumes that the Olmecs wasted no time in the research potential of the Long Count, and, second that in a very short span of time the original length of the year, 360 days (whose measure was incorporated in the Long Count), had been forgotten.

The "Day of Kan" for 685 BC

Having found, or verified, the "Day of Kan" for three past creations, the scribes and day-keepers seemed to have been satisfied, for these two dates were never again corrected or accessed. A more important problem came forward: What was the day which ended the most recent creation, the events which were witnessed in 685 BC? For this everyone had accurate records, to the day, and certainly for the sunset horizon locations.

We could imagine a conference of scribes, recorders, and day-keepers from surrounding cities and ceremonial centers convened at **Teotihuacan** sometime during these centuries for the purpose of hammering out the theological difficulties. Most sites already had alignments established long ago, selected from four dates in 685 BC, and a large number which recalled earlier era-endings.

The solution seems to have been to move the Long Count up by two days, by dropping what is known as the August 11 correlation for a competing August 13 correlation. This made it clear that the day Jupiter released its plasmoid thunderbolt, July 14, 685 BC, fell on the "Day of Kan" -- 6.3.4.5.4 2-Kan, on the August 13 correlation.

I should note that, considering the sacredness of the Tzolkin, it would seem next to impossible that the Tzolkin could have been moved by two days, as I have described above. More likely the August 13 version arose from an early misunderstanding in its adoption by some tribes, although it would have to be at a time when the Tzolkin and Haab were already widely distributed. Possibly this happened in 747 BC, when some tribes did not acknowledge the two days which were missing because the sun had not risen as the Earth's axis went through a spin.

The Long Count, where it was adopted, was added in each instance of its adoption to an on-going tally of the local Tzolkin calendar. The days of the Tzolkin (and the Haab) are the same sequence in both versions of the Long Count.

The Zapotecs of **Monte Alban** must have worked under the same prohibition of interrupting the calendar. Thus when they switched over to an annual calendar which would restart every year on August 14th, this must have been done when the day 1-Imix, the first day of the 260-day Tzolkin, corresponded to our calendar day of August 14th. This happened only three times in a span of about 2400 years, in 439 BC, 523 BC, and 607 BC. Of these three, the last date listed, corresponds to the first archaeological dating of the site of **Monte Alban**.

The Course of the "May"

We can thank the Olmecs for recording for us, in the site selections for ceremonial centers, the alignments of the heavens before and after the 7th century BC, and Vincent H.

Malmstrom for pointing these out to us. In the following few paragraphs I will review the changes already noted above and in the previous chapter, but in a broader historical perspective.

The sequence will be based on the fact that the interval between approaches of Venus was known by the people of Mesoamerica to be 52 years in an earlier era. The actual "Venus interval" at various times is detailed in Appendix B, "The Celestial Mechanics."

Munro S. Edmonson, in an essay "Some Postclassic Questions About The Classic Maya," proposes that, at least for Post-Classical and Colonial times, some Maya ceremonial centers were designated as a type of central capital city, for a term of 20 years, that is, the duration of a Katun. He writes:

"The Books [the Chilam Balam books] explicitly say they did. In the Postclassic and later the cycle seat ('may cu') was the primate city of a region. It was not a capital in any normal sense, but rather a holy city, recognized by the title Born of Heaven ('ziyan can, can sih'), and notable for its sacred ceiba tree ('yax che'), its sacred grove ('tzucub te'), its sacred well ('ch'en'), and its plaza, which was the crossroads ('hol can be') and navel of the world." [\[note 7\]](#)

Edmonson claims that there was a larger cycle consisting of 13 Katuns, an interval of about 256 years, and would suggest that this could be extended back in time. He notes that the period of primacy (the "may") always ends at Katun 8-Ahau. About the abandonments, he writes:

"The Postclassic Maya destroyed the primate city and its road at the end of the 'may.' There are indications that this 'destruction' may have been largely ritual and symbolic, and that the 'abandonment' of the city was an evacuation by the ruling dynasty rather than total depopulation."

"It is of some interest that the first three of these cycles come within three Katuns of accepted dates for the beginnings of the Olmec period, the Middle Formative and the Late Formative respectively, and that the earliest long-count dates of the next two cycles fall outside of Maya country as usually defined (Tres Zapotes, El Baul and Tuxtla)." [\[note 8\]](#)

I do not think we can hold that the later Katun endings used by the Maya could be extended backwards in time to **San Lorenzo** (but likely to the demise of **Teotihuacan**). But the concept of primacy of a single location seems to have existed. However, based on an inspection of spans of occupancy of various sites, I would suggest that we have to use a different cycle, not the rotation of 13 Katuns. Most appropriate, in the era when Venus was the main threat, this might have been an interval of periods of 52 years. As it turns out, a period of ten 52-year periods seems to have been in use -- 520 years -- which equals two cycles of 13 Katuns. Why this particular span of time? I do not know. The causes are lost in

prehistory, but it seems to have had a certain urgency.

It has been estimated that **San Lorenzo** was destroyed and abandoned in about 900 BC. The first Baktun and Katun ending in 8-Ahau after about 900 BC is 868 BC. Additionally, **San Lorenzo** was only in use after 1440 BC. If we use the first Baktun and Katun ending in 8-Ahau after 1440 BC, which is 4.9.0.0.0, 1367 BC, then the span of time to 868 BC is two cycles of 13 Katuns -- 520 years.

As it turns out, this cycle of 520 years can be readily traced forward (and backward) in time, to include, for example, the well-dated site of **Teotihuacan**. This 520-year period also hints at the fact that the previous era might have used the same measure. I will address this further below. Thus the primacy of **San Lorenzo** was from 1367 BC through 868 BC, when it was destroyed and abandoned. [\[note 9\]](#)

With the establishment of the Haab calendar (of 360 days) after 1492 BC, the people of Mesoamerica recognized a "world ending" date, when the same day name and number on the Haab and Tzolkin calendars recurred -- a period of 52 years (initially using years of 360 days). This interval became high science for the Olmecs, as well as all the later people of Mesoamerica, and it had a certain numerological beauty. In fact, I suspect that the whole of calendrical history after 1492 BC, when the Haab calendar was established, lies suspended between math and magic. As I have pointed out in an endnote to the chapter "Language and Causality," colonial native documents which propose to reveal the history of the region in deep antiquity, as for example, the *Annals of Cuahitlan*, make claims to ages of the world which are uniformly reported as products of 52 and 13 years and their differences.

We have no evidence that Venus might have aligned with Earth at regular 52-year intervals after 2193 BC. I have shown, in fact, that the period would have dropped to 47 (solar) years after 2193 BC, and was 50 years between 1492 BC and 1442 BC. (See Appendix B, "Celestial Mechanics.") Yet the expected end of the world was still celebrated at 52-year Haab intervals at the time of the Spanish invasion in the 16th century AD, even though by this time the dates of the "52-year round" had not coincided with alignments of Venus probably for over 2000 years. Except, of course, that Venus would still be seen rising at the same horizon location every 52 "years" on the Haab calendar.

I dislike numerological analysis of ancient history, but, considering the seriousness with which the Mesoamerican people seem to have approached this subject -- to the point where almost all of the Maya monuments deal exclusively with time periods and Katun endings -- it might in this instance be appropriate. I'll follow Edmonson's suggestion of the existence of the "may," but I will not use a single cycle of 13 Katuns (260 years), but a period of 2 cycles of 13 Katuns, 520 years ($2 * 13 * 20 = 520$ years). This is also 10 cycles of 52 years, and this is probably what defined the "may" in remote antiquity. I'll start with the second "may" in order to settle some dates and practices.

The Second "May" at San Lorenzo, 1367 BC to 847 BC

In Veracruz the oldest Olmec site, **San Lorenzo**, dating from around 1440 BC, shows two alignments with the mountains **El Chichon** and **Zempoaltepec**, for a date of an April 19 sunrise and sunset, recalling the start of the era after 1492 BC (actually the end of the previous era). An additional alignment with **Popocatepetl** signals the day (sunset) that the Sun passes directly overhead, on August 15. These alignments are for an axial inclination of 30 degrees.

I would suggest that the site of **San Lorenzo** was significant to the Olmecs in preventing the repetition of attacks on Earth by the planet Venus after 1492 BC, or, more likely, after 1440 BC (or 1442 BC). The giant heads excavated at the site would then represent Venus. A new head would be carved every 52 years (or 52 Tun-years) as Venus was expected to approach the Earth again, to be used in some preventive ceremonies, and buried when the crisis had passed. Starting after 1367 BC and extending to about 900 BC, some 10 or 11 giant heads would then have been carved and disposed of. Dates can be selected as multiples of 52 years, starting from 1492 BC. Even if the dates are not correct, dividing the 520-year span of time of the "may" by 52 yields an estimate of 10 heads. Ten heads have been found. [\[note 10\]](#)

The actual "Venus cycle" after 1440 BC was probably 50 years -- if it existed at all. But the 360-day Haab had been devised, and the Olmecs were thoroughly convinced that the appearances of the celestial Gods followed their calendar.

What I am suggesting is that the celebration of the "52-year interval" was most likely entirely ritualistic and based only on calendrical considerations. Thus, although the actual Venus cycle varies from 47 to 52 years, I have used a Venus cycle interval of 52 years throughout most of the chart presented further below. For the period of 2193 BC to 1492 BC I have used an interval of 47 years. This would be suggested from the fact that there was no Haab calendar until 1492 BC, and the intervals might represent actual sightings of Venus and would be counted in Tun years, representing solar years of whatever length.

About the heads, I would further suggest that they were indeed intended to resemble Olmec ball players (after all, Venus bumped the Earth like a ball player in 1492 BC), and may additionally be wearing flayed human faces as a mask, which last would account for the swollen lips and flattened nose. There is no question that the Olmecs played games with a rubber ball. That has been archaeologically established. A mask designates a person as representing a God, as is clear from contemporaneous and later iconography. That flayed human faces were depicted seems clear also from an inspection of smaller sculptures, shown with eyes in deep outlined sockets, incised lines along the left and right sides of the faces, flattened noses, and rolled back lips. A mask, or wearing a mask, was, since the Olmec era, the disguise of a God. [\[note 11\]](#)

After 520 years of preventing disaster, the site of **San Lorenzo** became irrelevant, and in about 900 BC the ceremonial center was destroyed and abandoned. I would suggest the year of 847 BC, the end of a "may," a period which will fit exactly between an earlier and many later "may" periods. First then, a look at an earlier period.

The First "May" at Monte Alto, 1887 BC -- 1367 BC

If **San Lorenzo** then held its period of primacy for "10 periods" of 52 years on the basis that some previous site had also held its primacy for an identical period of time (and was destroyed), what site was this? We do not really know, but it would have to be a site with an occupation dating back to about 2000 BC.

A likely site might be located in the **Soconusco** region of Guatemala, along the Pacific coast and in a tropical region similar to Mexico's Veracruz. This includes **Izapa, El Jobo, Abaj Takalil, Chocola, Chukumuk, Kaminaljuyu, El Baul, and Monte Alto**, all of which are located along a 120-mile coastal strip (in that order). All the sites share the same art style, and share this with **Tres Zapotes** in Veracruz. Some sites are dated to have had their start in the period of 1850 BC to 1650 BC, thus 200 to 400 years before the establishment of **San Lorenzo**. But dates to 2000 BC have also been suggested.

What is of interest is that 11 large undated carved heads or rotund bodies with heads ("fat boys") have been found in a cornfield near **Monte Alto**, the southmost site. Malmstrom describes them as:

"... large rounded boulders, often 1.5 m (5 ft) or more in diameter, were selected as the medium upon which either the rudimentary features of a head or a body were etched out in bas-relief. Only a minimal amount of carving was done, so in all cases the faces have a decidedly bloated appearance and the bodies are corpulent."

[Image: Stone head ("Monument 1") from **Monte Alto**, Guatemala. After Michael Coe, *"The Maya"* (2005).]

"The heads that were depicted tended to have a fairly similar, generic appearance. If they were intended to highlight any individual differences, their sculptors appear to have been singularly unsuccessful, although a few of the heads do have some strikingly unique characteristics."

"The bodies, on the other hand, almost invariably have the arms wrapped around them so the fingers of the hands nearly come together over the fullness of their abdomens, and the legs and feet often do a similar encircling act near the base of the sculpture."

There are other large sculptures in stone in the **Soconusco** region, including heads, turtles, and reclining jaguars. But the collection at **Monte Alto** is amazing and unusual. The oldest of these are estimated to date to 2000 BC.

The collection of "fat boys" suggests that, like at the later **San Lorenzo**, these might represent efforts at staving off the destructions which might have resulted from the expected passage of Venus at 52-year intervals. The sculptures would have been created over the course of 520 years, the term of the primacy of the site.

Elsewhere I have developed that in 2349 BC and 2193 BC (and in between) Venus made electric contact with Earth. That period would have observed four possible interactions with Venus. What I have also developed, in Appendix B, is that until 1492 BC, Venus would cross Earth's orbit regularly. This would not cause electric contacts, but Venus would have loomed very large in the sky at infrequent intervals. Likely this interval was 52 years, or more likely it was 47 years at that time.

Perhaps the preventive measures were initially (during the period between 2193 BC and 1492 BC) based on observation of a 47-year cycle. After 1492 BC, the Venus cycle changed again, but the newly established Haab calendar could track the interval correctly.

If during a 520-year period ending in 1492 BC the fat boy bodies were carved to coincide with the 47-year intervals, then we could divide 520 years by 47 to find that 11 sculptures would have been carved. Eleven heads and bodies have been found.

Assuming that the primacy of **Monte Alto** indeed extended to 520 years, then it seems that the efforts at the prevention of disasters carried right through the Pacific contact by Venus of 1492 BC which sent tsunamis across the Pacific, reaching to China, and certainly the whole of coastal South America and Central America. This may have been the event which made the shamans of **Monte Alto** conclude that the effectiveness of their services had come to an end. Did this happen in a Katun 8-Ahau?

Another solution, in line with later practices, would be to suggest that the nearest "8-Ahau" closing date after 1492 BC or 1442 BC would be in 1367 BC, the year 4.9.0.0.0 8-Ahau. Baktun 4 and Katun 9 were known, as was the fact that the last day of the Tun was 8-Ahau. Perhaps this showed that a site could only hold its mandate until ten cycles of 52 Tun years had lapsed and 8-Ahau was reached.

Following the event of 1492 BC, the Haab was established, and now a rotation through the two calendars would repeat any Tzolkin and Haab day name-number every 52 Tun years. The knowledge that, 700 years earlier the potential end of creation had indeed occurred at 52-year intervals, now became the method of choice in warding off the end of creation at **San Lorenzo**. Venus, however, never again crossed Earth's orbit after 1492 BC or 1442 BC, and the interval between approaches after 1492 BC was not 52 years, but 50 years. Actually, it seemed not to have mattered, what the calendars predicted was important.

An Earlier "May" Period before 1887 BC.

If indeed the site of Monte Alto in Guatemala was established in 1887 BC, then we can count another 520 solar years back from this date. That takes us to 2407 BC, 52 years before the plasmoid of Venus landed in 2349 BC. Seeing Venus overriding Earth's orbit (without a electric field contact) might have been enough to establish that date.

On the other hand, since at this point we are losing track of ancient history as determined by well known catastrophic events, it might be of use to suggest other events.

What comes to mind as a near coincidence is the length of time that the three ball plasmoids in the south stood in the sky before collapsing. In the first century AD the Egyptian Stoic philosopher Chaeremon suggested 500 or 540 years. The three periods would have to fit between 8347 BC and 10,900 BC (approximately 2550 years). I will suggest that the actual length of each of the three periods might have been 520 years -- or at least the last one.

The Olmecs or their predecessors were the only people on Earth to record details of the three southern plasmoids, their names, and their movement -- to be presented in capsule form 14,000 years later in the *Chilam Balam*. And, like many other people, they kept track of expanses of time -- huge expanses. If Josephus in the first century AD can offer a count of 1656 years between creation and the World Flood (even if applied to the wrong events), then certainly the Olmecs could count 520 years as the extent of the visibility of the southern ball plasmoids. Counting, as we saw in the decorated caves of western Europe, was high science. And counting establishes history, even for people who had no subjective consciousness and otherwise could not place themselves in a continuum of time.

Thus it is likely that the 520 year span of the 'may' represents a celebration or commemoration of the existence of the "first creation."

The Third "May" at Tres Zapotes

It is easier to identify a site which takes on primacy after **San Lorenzo**. The most likely choice seems to be **Tres Zapotes**. The site is located so that a zenithal passage of the Sun happened on August 13 during the time before 685 BC (and rose out of **Vulcan San Martin Tuxtla**). There is also an alignment for February 28, also conformed to the era before 685 BC. Strangely, there are additional alignments, also for before 685 BC, for July 25 (two) and July 9th. I would suspect that the site was relocated advantageously to pick up these additional alignments.

[Image: Rancho La Cobata stone head ("Monument 1"), 11 feet (3.5 meter) high. After micahwright.com]

San Lorenzo had performed their last preventive ceremonies in 892 BC. Thereafter, or soon thereafter, primacy passed to **Tres Zapotes** which proceeded to carve the large stone heads for the next expected approach of Venus. I would expect the first in 816 BC and a second in 764 BC -- two heads. Two heads have been found at **Tres Zapotes**. The third expected approach of Venus would have been 712 BC, but that event never materialized, for in 747 BC Mars shocked Earth, and destroyed **Tres Zapotes**. After 747 BC everything changed.

[\[note 12\]](#)

It might be suggested that an unusual head ("Monument 1"), found at **Rancho La Cobata**,

near the site of **Tres Zapotes**, was originally destined for delivery to **Tres Zapotes** for a Venus ceremony in 712 BC, but was never delivered -- because in 747 BC **Tres Zapotes** was destroyed.

Rancho La Cobata is thought to be a stone workshop for **Tres Zapotes**. The head found at **Rancho La Cobata**, and the two found at **Tres Zapotes**, are local and similar in style, differing from those found at **San Lorenzo** or **La Venta**.

The head at **Rancho La Cobata** is absolutely enormous. It stands over 11 feet high, whereas the heads found at **San Lorenzo** vary from 5 feet to 9.5 feet (1.5 to 3 meters) tall and the heads at **La Venta** vary in height from 5.5 feet to 8 feet (2 to 2.5 meters). But what is most unusual is that, unlike all the other heads, it was carved with closed eyelids and with a down-turned mouth similar to the "snarling" down-turned mouths found on the "were-jaguar" sculptures at **San Lorenzo** and **La Venta**. It is the face of a dead person.

This giant 11-foot-high boulder may have represented the death of Venus after the electrical jolt between Mars and Venus in 776 BC. The massive lightning bolt to Venus, which carved the 3000 miles long and five miles deep Valles Marineris on Mars, would have dropped the coulomb charge of Venus. Venus would have gone (even if only temporarily) to dark mode and lost its coma and tail. The lightning bolt (originating at Mars) would have been seen traveling toward Venus for twenty minutes to a half hour.

On the other hand, the bolt from Jupiter in 685 BC also was clearly seen to end the brilliant display of Venus and Mercury, and was likely understood as representing the end of threats by Mars (so reads the *Chilam Balam*), but killed Venus also. This head could thus also be dated to the second occupation of **Tres Zapotes**.

The Third "May" passes to La Venta after 747 BC

However, it seems that after 747 BC **La Venta** became the next center for the prevention of celestial disasters. Actually, **La Venta** had been established earlier, and it may have become the new religious capital by default. The change in primacy was unexpectedly soon, certainly not the 520 years that **San Lorenzo** had been in use.

La Venta became a primary ceremonial center after 747 BC, and certainly a likely founding date for **La Venta**, as a ceremonial center, would be 747 BC. The site was selected to have alignments for April 19, 1492 BC but also for February 28th, 747 BC. The alignments were conformed to an axial inclination of 30 degrees.

What is somewhat strange is the apparent switch at this time from Venus heads to Mars heads. The 52 Tun-year anniversaries were still celebrated, but with "creation" altars.

[Image: Olmec stone altar. After Wikipedia, Ruben Charles, under Creative Commons license.]

There would have been five opportunities to carve a head representing Mars (not Venus) and prevent disasters after 747 BC, if the date of 747 BC is included. Certainly Mars was prevented, through whatever ceremonies, from becoming "the God of hell" (as the *Chilam Balam* calls the attempts by Mars at ending creation).

Either four (or five) heads might have been carved before Bolon-ti-ku, Jupiter, called it off in 685 BC. Four heads have been found at **La Venta**. But five "elaborate tombs" have been found at the site, and five large caches of serpentine blocks. (The tombs will be reflected in the five houses used by the Gods of the underworld to keep the *Popol Vuh* twins, Hunahpu and Xbalanque, overnight, in attempts to kill them.)

I only slowly became convinced that the "heads" represented Mars ceremonies, and the "altars" represented Venus ceremonies. I'm inclined to think that the altars, already in use since **San Lorenzo**, represented "renewals of creation" ceremonies. This is still being celebrated today by Maya shamans, using, as earlier, an altar oriented to the cardinal directions.

Eight or nine basalt altars have been found. The ninth is not certain. David C. Grove, in "Public Monuments and Sacred Mountains: Observations on Three Formative Period Sacred Landscapes" (*Social Patterns in Preclassic Mesoamerica*, 1999), suggest 8 "altars" for sure, of which five are "table top" versions, six feet (2 meters) high and 12 feet (4 meters) wide (whose "purpose [is] still unclear to archaeologists"), with a projecting upper ledge, and a front niche -- like a cave entrance -- with a seated person. Four of the altars are positioned in pairs, where one has a person appearing from the cave-like opening, and the other is a "presentation" scene, with the person holding a were-jaguar infant. All these altars are located south of the **La Venta** pyramid (the heads and graves are north of the pyramid).

[Image: Olmec stone altar. After Wikipedia, Ruben Charles, under Creative Commons license.]

The altars are reminiscent of the 'creation' altars built by Maya shamans today. If the Olmec altars celebrated recreations of the world at 52-year intervals, then seven altars would span 747 BC to about 400 BC, when **La Venta** was abandoned. If started in 712 BC, the 6th altar would date to 400 BC. At a height of six feet, these are neither altars nor kingly thrones (as some archaeologists hold), but models of the raised sky. At any rate, only six or seven kings in 350 years is not likely.

Grove also notes that the table-type altars, with the exception of the fifth altar, are always placed in sets of two, the first with a person peering out of the cave, facing the second where another person holds a were-infant on his lap. The pairing may be a coincidence, although this happened at **San Lorenzo** also. Even though I do not have enough altars, I'll assume that they were created every 52 years as single pieces rather than in pairs.

The theology of the Olmecs changed after 685 BC at **La Venta** as everywhere else in the world. The emphasis changed from warding off Mars to celebrating Jupiter as the God of deliverance. This resolved at **Teotihuacan**, some 400 years later, to considering Quetzalcoatl, Venus, as the savior God through his self-sacrifice. The understanding reached in Mesoamerica of the events of 685 BC was in essence no different from the understanding achieved in the Eastern Mediterranean region. The missionaries who followed the Spanish invasion after AD 1500, quickly understood the philosophical underpinnings of the Indian "idol worship," and at first considered that Christ had perhaps appeared to the Mexica and the Maya independent of his appearance in Israel.

When the inclination of the Earth's axis changed to 23.5 degrees after 685 BC, **La Venta** was remodeled (and the first monumental construction was started), aligning the long axis of the site to be at a right angle to the new horizon location for the date of February 28, 747 BC.

The zenithal Sun still set in the volcano **San Martin Tuxtla**. The giant heads and the "number 9 Jaguar" mosaics, all of which were likely created after 747 BC, were retained or relocated.

The carved monuments at **La Venta** clearly recall the events of 685 BC. This is shown in the iconography of stela and engraved ceremonial objects, and, in fact, by the creation of the first pyramid in Mesoamerica. The pyramid, a "red house," is the image of the lower plasma expulsion of Jupiter in 685 BC.

After having prevented the ending of creation in the era after 747 BC, and no doubt continuing with other functions for an additional 300 years, the religious utility of **La Venta** eventually also came to an end. The "may" came to an end. There was no reason to carve additional stone heads. The shamans knew, too, that the site was not aligned with what was now considered the newest location of the end of the previous creation. There were no alignments to the dates of 685 BC at **La Venta**.

When was **La Venta** abandoned for another location? Archaeology suggests 400 to 300 BC. That suggests 7 periods of 52 years after 764 BC, when **La Venta** most likely took over the mandate from **Tres Zapotes**. If we carry the 520-year period forward from the ending year of 868 BC at **San Lorenzo**, the end of the "may" would fall in 334 BC for **La Venta**.

The Third Conquest

What is interesting, with respect to the status of **La Venta**, is an obscure reference to the ending of the second and third 52-year period at **La Venta** from inscriptions at the Maya site of **Yaxchilan**, 1300 or 1400 years later.

At a number of Maya ceremonial sites, ballcourts are named as "First Conquest," "Second Conquest," and the "Third Conquest," and more frequently just as "Third Conquest." At the Maya site of **Yaxchilan**, three ballcourts are inscribed with a dedication date of October 21, AD 744.

My first guess was that the date of AD 744 might have represented a multiple of 520-year intervals ("may cycles") since some important date in antiquity, especially since dates were in each case appended to indicate the first manifestation of the event significant to each of three ballcourts. The appended dates all point to the seventh century BC. As a matter of fact, AD 744 is 3 times 520 years (1560 years) since the first manifestation of the first colossal head at **Tres Zapotes**, in 816 BC.

"Conquest," as Schele and Freidel note, in *Maya Cosmos* (1993), was originally translated as "Creation" -- creation of the world -- which is probably more correct in the context I am presenting here. Schele and Freidel note that "manifest" might also have been intended. I would easily suggest "Reign."

I have estimated that first, second, and third "Creation Altars" were built at **La Venta** in 712 BC, 660 BC, and 608 BC. These might have been recorded in ancient records as the "first," "second," and "third anniversary" of "creation" or misread as the actual creation dates. Information on these ventures was available to Maya sites through copies of "The Council Book" which, since 747 BC, had recorded events at **La Venta** by Long Count dates.

The distance numbers of the Long Count dates of the three ballcourts are incomplete, so that at best Schele and Freidel could only suggest "1400 years before" the dedication date of the ballcourts in AD 744. That places the dates of the original "First Creation," "Second Creation," and the "Third Creation" in the era when **La Venta** was the center of religious activity. As Schele and Freidel point out, the calculations based on distance numbers do not match the Tzolkin and Haab day names and numbers of the inscriptions. The three Tzolkin/Haab dates are 13-Manik 5-Pax, 9-Kan 12-Xul, and 1-Ahau 13-Xul.

Using only the two distance numbers referenced by Schele and Freidel in a footnote, Long Count dates can be derived from a dedication date of 9.15.13.6.9 by subtracting the two recorded distance numbers of 3.8.10.14.11 and (3).5.19.0.7, resulting in 6.9.14.6.2 (September 19, 557 BC) for the "Second Creation" and 6.7.2.9.18 (September 2, 608 BC) for the "Third Creation." These match the dates of the fourth altar (for the "Second Creation") and third altar (for the "Third Creation") at **La Venta**, in 556 BC and 608 BC. (I do not know why the cardinal numbers are chronologically reversed.)

The date for the "Third Creation" is correct at 608 BC. This is (or should be) the date of the third altar in a series that was carved at **La Venta**. It would seem from this that a "Third Creation" was thus correctly pinpointed by **Yaxchilan** even though it was not the "third creation" they were looking for. They were looking for the date when the sky had turned red and fallen to Earth in 2349 BC.

The problem with the distance numbers of the three ballcourts (of which I only have two) is that the Calendar Round day names for the remote dates do not match what would be expected from a retrocalculation of the Long Count. We could search the 8th and 7th century BC for significant dates based on the day names. Calendar Round day names repeat every 52 years in the 520-year period (the "may") from Baktun 5 / Katun 15 to Baktun 7 / Katun 1. There are quite a few dates to check. Few of them make much sense. [\[note 13\]](#)

I think the scribes at **Yaxchilan** made a serious mistake. They were looking for the ending dates of the "first creation," the "second creation," and the "third creation," which would have been the years 8347 BC, 3147 BC, and 2349 BC. These three are the recognized completion dates for the "first creation," "second creation," and "third creation" as we know from other sources.

The scribes checked their records, the same records which had been recorded at **La Venta** and transcribed by others, eventually to be confused as the complete history of humanity. Some of the books, without giving dates, indeed did record events dating back thousands of

years, but references to the first, second, and third creation were recorded also for ceremonies at **La Venta** in the 7th century BC. The dates were transcribed by **Yaxchilan** without a single thought about the actual scope of history.

More importantly to compound the error, the records might have been "corrected" by the scribes at **Monte Alban** to conform to their particular calendar. This might have kept the years to more or less the same values, but would have jumbled the Tzolkin/Haab day names.

Let's follow this trail in the manner told in the Guatemalan *Popol Vuh*. I would assume that the scribes at **Yaxchilan** derived their information from books obtained from **Monte Alban**, but these books described information originally obtained by **Monte Alban** from **La Venta**. Those same books might repeatedly have been recopied before reaching **Yaxchilan**, but they were held as sacred and true. The books told of how the leaders (of **Monte Alban**) traveled east to the city by the sea (**La Venta**) to obtain their insignias of leadership. Received from **La Venta** were the "Council Book," and books called "The Light that Came from Beside the Sea," "Our Place in the Shadows," and "The Dawn of Life."

The books revealed the most ancient of history, the experience of darkness, the migrations of the tribes, the genesis of the Gods, the founding of the calendar, the "third creation" -- but all from records derived from **La Venta**. The books were probably not transmitted until hundreds of years had passed, and with time the stories they told were taken as the history of those who received the copies.

The Fourth "May" at Monte Alban, 334 BC to AD 179

The dates match. **Monte Alban** was active before **La Venta** was abandoned. It was at **Monte Alban** also where a script was developed. The Tzolkin and Haab calendar was not received from **Monte Alban**, for everyone already had the calendar, as shown by the fact that the August 11 version was in use in both the southern Veracruz region (as at **La Venta**) and in part of Guatemala, whereas the Valley of Mexico and the Guatemalan Peten and the Yucatan region used the August 13 version.

The "may" ended in AD 179 for **Monte Alban**. But **Monte Alban** was not destroyed after AD 179, but held on to AD 700 or AD 1000, after which it was mostly abandoned. By the 16th century AD there was still a priestly college in the Oaxaca region, which seemed to have remained unmolested by the Aztecs.

Interestingly, **Monte Alban** did not go into a decline until AD 700, suggesting that perhaps it held the "may" for two periods, from 334 BC to AD 179, and from AD 179 to AD 692. This last is the same period when **Teotihuacan** obviously held primacy. Perhaps this is an instance of the regionalization of the "may" since **Monte Alban** was a considerable distance from the Valley of Mexico. Because of my use of the Gregorian (Julian) calendar at this point in time,

the "may" since **La Venta** is reduced to 513 calendar years.

The Fifth "May" at Teotihuacan, AD 179 to AD 692

Clearly it was **Teotihuacan** which held the "may" from AD 179, to be abandoned, "conquered," in AD 692. As I have noted, **Teotihuacan** was one of the three largest cities in the world. **Teotihuacan** established a widespread trade network across Mesoamerica. There was a population of **Monte Alban** craftsmen in one of the precincts of **Teotihuacan**.

Following the Post-Classical usage by the Maya, it would seem that by "conquest" is also meant the destruction and abandonment of a ceremonial site after some period of use, as Edmonson has suggested. This has been seen in the case of **San Lorenzo** and **La Venta**, and has recently been suggested for **Teotihuacan** in about AD 700. At an earlier time the destruction had been attributed to the Toltecs who invaded the Valley of Mexico. Today it is attributed to the priests of **Teotihuacan**. Assuming that the cycle of primacy is indeed 520 years, it could be suggested that **Teotihuacan** took on primacy shortly after AD 172. This agrees, in fact, with the archaeology of **Teotihuacan**.

At the beginning of this period, outside of the Valley of Mexico, in Honduras and the Peten of Guatemala, the Maya seriously start up their own ceremonial centers, and start up the celebrations of Katun endings, and any number of other dates which were perceived as important in sustaining the world. These are discussed by Edmonson. The Maya seem to have disregarded the "may" as it was defined in the Valley of Mexico, but retained the concept of a primary regional site. In this respect the Toltecs of Tula may have done the same. [\[note 14\]](#)

The Sixth "May" at Tula, AD 692 -- AD 1219

In the Valley of Mexico it was an invading tribe, the Toltecs, who built and occupied the city which is today known as **Tula** or **Tollan**, and which seems to have held primacy after **Teotihuacan**. **Tula**, however, was not built until after AD 900 and destroyed sometime around AD 1170, after which the primary city of the Toltecs was reestablished elsewhere. Their calendar dates from AD 726. During this period the Toltecs dominated much of Central Mexico. After AD 900, **Tula** was the largest city in Mexico. [\[note 15\]](#)

When **Teotihuacan** was abandoned in about AD 700, the Pleiades passed directly over the city at culmination. When **Tula** was constructed 200 years later and at a half degree further north in latitude, the Pleiades passed directly overhead of the new ceremonial center.

The word "Tulan" or "Tollan" means "place of the reeds" or "place of the rushes." It had been

applied to **Teotihuacan** also, and the later Aztecs applied it to their own city of **Tenochtitlan** (today Mexico City) as well. Not much is known of **Tula** since the Aztecs plundered it for building material and sculptures.

Nine intervals of 52 years had passed since **Teotihuacan** was abandoned, when **Tula** was conquered by invading tribes. The architecture of **Tula** subsequently shows up at the Maya site of **Chichen Itza**.

The Seventh "May" at Cholula, from AD 1219

Cholula was a very large city southeast of the Aztec city of **Tenochtitlan**, and only a little smaller than **Tenochtitlan** in the 16th century AD. Dating from about 200 BC, it lasted to the time of the Spanish invasion. *"Cholula remained a regional center of importance, enough so that, at the time of the fall of the Aztec empire, Aztec princes were still formally anointed by a Cholulan priest"* (Wikipedia).

Cholula probably had a population of near 100,000. The center included the largest pyramid in the world. Cortes reported counting 430 temples (there were only 365). When Cortes arrived, he massacred 3000 nobles and priests of **Cholula** in two hours, to demonstrate to the neighboring cities the invincibility of the Spanish.

The "May" among the Maya

Edmonson suggests that the Maya may have redefined the "may" to a reduced period, as little as a single twenty-year Katun, rotating primacy among 13 prominent sites, although there also was a much longer period. Among the Maya the long 520-year period of the "may" seems to have been defined from the time of the fall of **Tula** (AD 1170, with AD 1204 as the end of the "may").

Edmonson identifies **Mayapan** of the (Maya) Itza as holding primacy from AD 1243 to 1752, a 509-year period, starting in a year 6-Ahau (20 years after 8-Ahau) and ending in a year 8-Ahau (and thus one Katun short of 520 Tun years), even though **Mayapan** was deserted during the last 300 years. The Toltecs in the Yucatan (remembered later as the Itza) used the start of the 11th Baktun (11.0.0.0.0) as the start of a "may." Edmonson further shows both the startup and the collapse or abandonment of numerous sites in the Yucatan as coinciding with Katuns ending of 8-Ahau.

It could be suggested that the Classical era Maya sites in the Peten fully expected to last to the end of the next 520-year interval after the "conquest" of **Teotihuacan**, that is, to AD 1212. None of the highland Maya sites did. They all floundered and were abandoned by about AD 900.

Summary

What will be seen in a list (below) of ceremonial centers and cities, is a sequence of events which promotes each city in turn to the status of a major center of activity and extended hegemony for a period of somewhat under 520 years, after which it disappears from view. As a primary center, they were consistently the largest and most populous sites, they conducted trade over nearly all of Mesoamerica, and were widely influential in promoting their architecture and their iconography, and -- we would presume -- their religious ideas.

Over a period of 3000 years, the expectations of the sequence of the "may" in almost all instances matches the archaeological dating, although it is not always quite clear-cut. Some sites are already established at the start of a "may," but others, like **Teotihuacan** and **Tula** spring into existence as new ventures. Probably more important is that **San Lorenzo**, **La Venta**, and **Teotihuacan** clearly were destroyed by the residents or the leadership of the centers. The destruction of **Tula**, although at about the right time for a "may" ending, is today attributed to other invading tribes.

As time progressed, hegemony over the region is expressed more and more with force, culminating with the extreme militarism of **Tula** which extended its control into Guatemala and even into the Yucatan region of the Maya. The later Aztecs took up the concept of military control after the fall of **Tula**, and claimed themselves as their descendants. **Cholula** seems to have avoided militarism, since it existed in the shadow of the Aztec empire.

Abandoning a site after a set span of time is a concept entirely foreign to our way of thinking. It is a disruptive, self-defeating, and senseless gesture, and can only be understood if seen as a religious necessity. The nations of Europe often act the same way, but somehow their religiously based actions make more sense to us.

The following table lists Katuns ending in 8-Ahau and anniversaries of the 52-year Venus cycles, in addition to a few other events. The 52-year intervals, shown below, are based on "Venus cycles" in solar years before **San Lorenzo**, and on 52 calendar years afterwards.

Baktun/Katun 8-Ahau ending	corrected date (see note 1)	Venus 52-year cycles marked (*), and other notes (see text)
1.17	2407 BC	possible start of an earliest "may"
	2349 BC	(*) The "flood of Noah"
	2297 BC	(*) 2nd appearance of Venus
	2245 BC	(*) 3rd appearance of Venus
	2193 BC	(*) The fall of Akkad

	AD 1519	Cortez massacred 3,000 Cholulans	
Note 1: "Corrected dates" are Baktuns and Katuns as solar years, except that after La Venta (after 747 BC) the interval on our calendar is 513 years.			
Note 2: Prior to 2193 the "Venus cycle" consisted of 52 solar years.			
Note 3: For the period of 2193 BC to 1492 BC, the "Venus cycle" is based on an interval of 47 solar years, marked #.			
Note 4: After 1492 BC I have used a 52-year "Venus cycle."			

The "years BC" for the 8-Ahau Katuns listed above are corrected by assuming, as would be the case before 747 BC, that the Baktuns and Katuns represented actual years, that is, solar years. This matches dates from the Eastern Mediterranean, where the "BC" notation is also in solar years (today under the assumption of an invariant year length). The 52-Tun-year anniversaries of Venus are shown in BC/AD notation, and are thus approximate. Since the final celebration in the Valley of Mexico happened in AD 1507, my series of 52-year anniversaries, which ends in AD 1472, is off by 35 years near the end. I have added Malmstrom's derived dates for the period after **Teotihuacan**.

From this table it would be clear that primacy of a site is concluded after the 10th anniversary of the 52-year Venus cycle, whether the cycle existed in reality or not. This assumes a missing primacy between **La Venta** and **Teotihuacan**, for which I have suggested **Monte Alban**, although **Tres Zapotes** was also revived.

Considering the role played by **San Lorenzo** and **La Venta** in the maintenance of creation and prevention of the destruction of the world for over 1000 years, it becomes obvious that these two sites were very important and influential, and possibly would have set the religious agenda for Mesoamerica for the following 2000 years.

As I have noted earlier, most of the other Olmec sites, and most of the sites in the Valley of Mexico, show the same concern with "era-ending" alignments similar to what was incorporated in the choices for the location of **San Lorenzo**, **Tres Zapotes**, and **La Venta**. The alignments established at **San Lorenzo** and **La Venta** became the minimum required alignments. After 600 BC new "era-ending" alignments are added, reflecting dates from the year 685 BC.

It could be suggested that the older horizon locations (like for April 19, 1492 BC, or February 28, 747 BC) were simply copied from the older sites, except that we start to see these older alignments being conformed to the new axial inclination of 23.5 degrees, just as we also see some of the newer "era-ending" dates configured to horizon locations conformed to the old axial inclination of 30 degrees. This is a truly strange procedure, and it is almost beyond the imagination to attempt to understand how the alignments for the previous era could have been found geometrically. But it is clear that it happened. We also have absolutely no idea what was so important about establishing these site alignments.

Orientation of the major axis of a site would be the easiest method of forcing the "proper" layout of a ceremonial center, one which did not require triangulation with two or more mountains. There might have been many more than the few I have noted. Unfortunately I am lacking axial locations of site orientations except for a few well-studied sites and I may be missing additional horizon alignments because of this.

The alignments used to signal the end of yet another creation were not immediately obvious after 685 BC. Which date to use, and how it reflected new developing theologies, remained a question. Using two revolving calendars which did not match the solar year did not help to resolve this initially. There were many understandings of what had happened, and many solutions. We also do not know how these calendars were used. Probably the alignments implemented by **Teotihuacan** were adopted by the Maya in the Peten and on the Guatemalan coast, due to the hegemony that **Teotihuacan** exerted over much of Mesoamerica. Again, I have also not followed up on site alignments in the Yucatan or Guatemala. The alignments found for Veracruz and the Valley of Mexico were, I felt, sufficient to establish the importance of site alignments, but especially to demonstrate the change in the inclination of the Earth's axis of rotation.

The events of 685 BC were of course written down. There would have been day books, records of events by years and by days. Narrative versions probably came much later, and likely encompassed all of sacred history, from the first creation onward. The understanding of what transpired in 685 BC probably took many forms. But everything that was told in the narrative could be verified.

What does all this mean? It means that we are dealing here with able historians, excellent geographers, superb observational astronomers, and astute mathematicians. Before the Spanish destroyed all their records, these Stone Age people had the longest continuous historical records in the world, the only accurate record of past celestial events, and the closest observations of the Sun. We only need to get past their quirky concepts of geography, and their strange notions of cyclical time and disregard of the actual length of the year, in order to extract information which other nations of the world have failed to record or make sense of.

Endnotes

Note 1 --

The misapplied science involves the use of the August 13 correlation. It is the only one where the day-names hold up. It differs from the August 11 correlation, which was certainly in use in 747 BC, and had spread with an attached Long Count to Guatemala before 600 BC.

[\[return to text\]](#)

Note 2 --

The Olmecs, and certainly the later Maya, were perfectly capable of dealing with the 0.24 fractional day. So says Michael Coe. The Maya used ratios to approach the values of numbers less than one, similar to the Egyptian use of additive fractions in doing division.

[\[return to text\]](#)

Note 3 --

The association of the "Day of Kan" with the flood of Noah (the fall of the Absu) is not entirely certain from a reading of the *Chilam Balam*. Katun 9-Ahau is clearly identified, however, and this is immediately followed by, "Kan was the day when its burden was bound to it," after which follows, "Then the water descended, it came from the heart of the sky for the baptism of the House of Nine Bushes." It is quite possible that the (supposed) sentence about the "Day of Kan" belongs elsewhere in the text. (All sentence punctuation is missing from the "Chilam Balam" and the order is systematically jumbled.) The fact that the opening "Day of Kan" falls in Katun 9-Ahau, 2.2.0.0.4, would argue against this, however.

[\[return to text\]](#)

Note 4 --

The use of the August 11 correlation used to find these two day names in remote antiquity is another sign of the disagreements in Mesoamerica about the actual ending date of the era before 747 BC. After 747 BC the Day of Kan coincidences are to be found only with the August 13 correlation.

[\[return to text\]](#)

Note 5 --

All people do this: find similarities, and assume a connection. We frequently make these connections on a very slim basis. The Olmecs had assumed that a flood would separate recreations of the world, based on the flood of 3147 BC and the celestial flood of 2349 BC, which last had also caused incessant rains and storms. The *Chilam Balam* still acknowledges this connection, offering events surrounding 2349 BC as the "Third Reign." But the Earth shock of 1492 BC had not involved flooding of the scope of the previous era-endings, although the west coastal regions of the Americas were buffeted with massive tsunamis. With the shock of 747 BC any global flooding was missing, except, of course for the hurricanes due to the electrical arc from a passing planet.

Note 6 --

Malmstrom in "Architecture, Astronomy, and Calendrics" (*Pre Columbian Mesoamerica Archaeoastronomy in the Americas* - Ray A. Williamson, ed. (1981)), writes:

"From field measurements begun in 1971, Aveni was able to confirm that 50 of 56 sites which he examined were indeed oriented east of north, and that a 17-degree 'family' of alignments did in fact seem to exist (Aveni 1975) [Antoni Aveni, ed. Archaeoastronomy in Pre-Columbian America (1975)]. Aveni also concluded that this particular pattern of orientation seemed to be most prevalent in the Valley of Mexico and he specifically mentioned Tenayuca, Tepozteco, and Tula as sites where this alignment was encountered. (It should be pointed out that Aveni's '17-degree family' of alignments includes orientations as far off as 15.5 degrees, [azimuth of 285.5 degrees, less 270 degrees] for he includes Teotihuacán in this 'group'.)"

STRUCTURES ORIENTED TO ~285 degrees					
General Region	Site	Time-Frame	Structure	Orientation face	Measurement degrees source

-- Mexican plateau --					
	Teotihuacan	A.D. 0-650	Pyramid of the Sun	Front	*285.5 (M)

<p>note a (*) -- The present author [Malmstrom] has chosen to re-define Aveni's "17-degree family" of alignments as the "15.5-degree family" inasmuch as the principal structures in the major sites of Mesoamerica appear to center on this value; see asterisked items above.</p> <p>note b -- Sources of measurements: A: Aveni; B: Bernal; M: Millon; M-D: Malmstrom and Dunn. Inasmuch as the author (Malmstrom) and his assistant carried out their measurements with a surveyor's compass, wherever data obtained by more precise instrumentation are available, they are cited instead--rounded to a tenth of a degree.</p>					

I have reproduced a chart of results by Malmstrom above. Because Malmstrom specifically notes that some of these values have been corrected by him, I do not have confidence in the original data. Malmstrom notes that:

"Aveni has had to dismiss all later sites built on the Mexican plateau having similar orientations to Teotihuacan (such as Tenayuca, Tepozteco, and Tula) as being simply 'non-functional imitations' of the great Mesoamerican metropolis (Aveni 1975)."

It is difficult to believe the chauvinism that a statement like this reveals. Aveni's alignments are reproduced in *Skywatchers of Ancient Mexico* (1980).

The problem I have with the arbitrary assignment of Aveni's "17-degree family" to the "15.5-

degree family" is that the 17-degree alignments are likely to represent the setting of the Pleiades in about AD 200 or AD 400, as determined by **Teotihuacan**. (See the text for this.)

Malmstrom suggests (correctly) that the 15.5-degree east of north alignments represent a sunset on "August 12-13," and writes:

"Of these two possibilities, the latter is definitely the more interesting to students of Mesoamerican calendrics. This is because the Maya -- the most highly advanced of all Mesoamerican peoples in the realm of astronomy -- believed that the present era of the world began on August 13, 3114 B.C., according to the Goodman-Martinez-Thompson correlation between the Maya and Christian calendars."

"... recurrent building alignments throughout Mesoamerica appear to commemorate a date which can only have had astronomical (solar) origins or, at the very least, could only have been established by astronomical means -- that is, by counting the number of days from some fixed point in time. (In the latter regard it should be pointed out that the August 13 sunset position could easily have been defined simply by counting 52 days from the summer solstice.) In the light of the evidence at hand, one can conclude that far from being just one more in a series of 'coincidences,' the correspondence of building alignment azimuths throughout Mesoamerica and the beginning date of the Goodman-Martínez-Thompson correlation should more realistically be considered as additional proof of the validity of the latter."

For the locations where I have accurate alignments based on current GPS data, I arrive at a date of August 12, not 13. August 13 is the day after, and thus after the "completion" of the previous era.

Note 7 --

Munro S. Edmonson, "Some Postclassic Questions About The Classic Maya" (*Fifth Palenque Round Table*, 1978).

[\[return to text\]](#)

Note 8 --

See <http://www.mesoweb.com/pari/publications/RT04/Edmonson.pdf> (1978). Edmonson also notes:

"The seat of the Katun ('hetz' Katun) was the real capital of the region in Postclassic and Colonial times. Though it only served for 20 Tuns at a time, each city competed vigorously for the honor, since it conferred tribute rights and the right to confirm titles to land and public office throughout the region. While these rights must have belonged to ruling lords of major centers, there may nonetheless have been some ritual rotation of subsidiary responsibilities among the cities of the second rank."

"Councils of sages and prophets were held at Mayapan and Chichen Itza in 13 Ahau (1539) and at Merida in 7 Ahau (1579). Such councils were apparently called in times of crisis to resolve calendrical and religious issues, and one such may well have been responsible for the founding of the League of Mayapan in 2 Ahau (1263). They appear to have resembled the Vatican Councils in function, and they commanded enormous respect, representing in Colonial times the highest moral authority in the country. Such a body might for example have had a role in the investiture of the rulers in Classic times as well as later."

"The ritual importance of the Katuns is fully attested by Katun ending monuments. Perhaps some of these contain texts with the curious blend of prophecy and history presented in the Books of Chilam Balam."

"[A] table has been drawn up as a documentation and speculation in relation to the recurrence of the 'may' cycle ending on 8 Ahau Katuns and its possible relevance to the chronology of Maya history. As is summarized in Table I in the text, it is possible to consider eleven such cycles within the framework of Middle American prehistory, from the ninth century B.C. to the twentieth century A.D. The eleventh such cycle would be completed in 2016 A.D., according to the most recent Maya calendar reform, that of Valladolid."

[Table not reproduced]

[\[return to text\]](#)

Note 9 --

The interval in solar years will match the count recorded by the Olmecs in "Tuns," since a Tun is (was) a (solar) year. Their records would thus match the chronology of the Eastern Mediterranean region. After 1492 BC the year went to 360 days, and a Tun was still a solar year. After 747 BC, when the Long Count was established, the Tun of the Long Count tally was retained at 360 days, even though the Haab year went from 360 to 365 days in 747 BC.

Is that interesting and indicative of the process?

David C. Grove, in "Public Monuments and Sacred Mountains: Observations on Three Formative Period Sacred Landscapes" (*Social Patterns in Preclassic Mesoamerica*, 1999), suggests nine or ten altars for **San Lorenzo**, writing (I am counting altars in the quoted text):

"Only two unequivocal tabletop altars have been found at San Lorenzo. Monument 20 (Type B) was found in the far northwest area of the plateau. Monument 14 (Type A) is positioned in the west-central sector of the site. Although separated by more than 400 meters, these two altars are in a virtual north south alignment."

"Evidence suggests that several other tabletop altars had also been displayed on the plateau at some time. Monument 18, in the southeastern corner of the South-Central Ridge, is apparently the basal fragment of a tabletop altar. The stone's low-relief carving depicts a pair of dwarfs, each with one upraised arm, as if to 'support' the missing tabletop. Monument 60, on the east side of the plateau near head 1 may likewise be a basal fragment." [4 pc so far]

"The most interesting evidence, however, is the astute observation by James Porter (1989) that oddly sculpted areas on two of the site's colossal heads (2 and 7) indicate that these monuments had been altars before being recarved into their present form." [6 pc total]

"Four other carvings have also been classified as altars at San Lorenzo: two large rectangular stone slabs, Monuments 8 and 51, and two 'circular altars,' Monuments 16 and 64. Both rectangular slabs are positioned in the same general east-west 'latitude' of the plateau as the Monument 14 and 60 altars. On the other hand, the 'circular altars' are located on the plateau's Southwest Ridge. There they appear to be positioned along an extension of the north-south alignment formed by Monuments 14 and 20." [10 pc total]

At 52-year intervals, the ten altars represent 520 years. We would do well to recognize 'altars' as marking 52-year intervals in the future, after **San Lorenzo**.

[\[return to text\]](#)

Note 10 --

How correct could I be about the number of heads found at **San Lorenzo**, **Tres Zapotes**, **La Venta**, and **Monte Alto**? In originally writing this chapter I guessed from calendar considerations at the number of heads at each of these locations without prior knowledge of how many there were -- **San Lorenzo**: 10 or 11 heads (10 have been found); **Tres Zapotes**: 2 heads (two have been found); **La Venta**: 4 or 5 heads (four have been found), and 7 altars (eight have been found); and **Monte Alto**: 11 heads (eleven have been found).

It was thus distinctly rewarding to find my estimates were confirmed in all cases. This could stand as "confirmed predictions" of a theory -- the theory being the 520-year extent of primacy of ceremonial sites -- except that I could be accused of having looked up the archaeological discoveries beforehand. What I did know beforehand was the approximate archaeological dates of the start and demise of the "may" locations, of which **Teotihuacan** was the most discrete example. These suggested a much longer span of time than what Edmonson originally proposed, which was mainly based on data from Maya sites. Edmonson wrote:

"In the Post-classic the seat of the cycle for the Itza, the 'Well of the Cycle' or 'Mayapan' from 1243 to 1752, was not even inhabited after 1452, but it continued to serve as a symbol of the religious authority of the 'may' for another three hundred years."

One would think that the 300-year abandonment of Mayapan, during which time it was still recognized for its "authority," would have hinted at a longer cycle, as plainly as the 509 years of its life.

[\[return to text\]](#)

Note 11 --

Peter Furst, in an essay "The Olmec Were-Jaguar Motif" in *Dumbarton Oaks Conference on the Olmec* (1967), argues the opposite: that statuary shows the human face as having been flayed to reveal the "inner jaguar" and reads this as a shamanistic motif.

At **Teotihuacan** warriors start using the flayed human face as a shield, and introduce this to the Maya during the Classical Period.

Not to be dismissed is that the Olmecs represented an influx of West Africans, who brought their language and script, but adopted the local calendar and history books. See, for example, the writings of Clyde Ahmad Winters on this, as *Atlantis in Mexico* (2005).

[\[return to text\]](#)

Note 12 --

The July 25 alignments and the July 9th would have been instituted in the second occupation of the site. The alignment for an axial inclination of 30 degrees probably reflects a convenience in rebuilding the site after 747 BC.

William Mullen in "Catastrophism and the Compulsion to Meaning" (*Kronos*, Vol. 6:1, 1980) wrote, *"Much of the Early Tres Zapotes level was sealed with volcanic ash."* He also notes the deposition of bitumen or asphalt. Bitumen is not volcanic. There were two occupations of **Tres Zapotes**. Bitumen was also found at **San Lorenzo** (Coe).

[\[return to text\]](#)

Note 13 --

The "First Creation" date of 13-Manik 5-Pax first occurs on 5.17.6.0.7 (802 BC), and every 52 years after. The second instance (5.19.18.13.7) happens in 750 BC. This is three years further in the past than the appearance of Mars in 747 BC. This date would have been recorded as the first instance in the Long Count records (the "Council Books"), but was actually the fifth instance since close calls were initiated in 806 BC. The date of 750 BC might qualify as an equivalent astronomical date for a Gregorian calendar date, except that I would expect a difference of four years, not three years. But it might do.

The "Second Creation" date of 9-Kan 12-Xul first occurs on 5.16.19.7.4 (808 BC), and also repeats every 52 years. The third instance (6.2.4.15.4) happens in 704 BC, two years after 702 BC, the fourth appearance of Mars.

It is very possible that the ceremonies involving the appearances of Mars were delayed by months or years, so that we simply have no way of knowing what the actual date was for the carving and burial of a stone head.

This is not true of ceremonies involving the "Creation Altars" which were governed by the calendar rather than some cataclysmic event. Thus it is interesting that one of the dates for the "third creation" day names of 1-Ahau 13-Xul falls on 6.7.1.3.0, which is 609 BC, and only 498 days (1.3 years) different from the Long Count date found from the distance numbers.

A difference of 1.3 years between the calendar date derived from the Long Count and the calendar date derived from the Calendar Round suggests that perhaps we are looking at records which were altered, that is, "corrected," by **Monte Alban**. It was in 607 BC, as I have pointed out above, that **Monte Alban** dropped the repeating Tzolkin calendar for a system where the Tzolkin would be restarted in the 365-day year after the first round, and then cut short after the 105th day. The Long Count was continued, but after the first year of the new calendar, the Tzolkin was displaced by 155 days, by 310 days after two years, and by 465 days after the third year.

[\[return to text\]](#)

Note 14 --

Ralph L. Roys, in an appendix to *The Book Of Chilam Balam Of Chumayel* lists a "Chronological Summary" of founding and abandonments of sites in the Yucatan, with respect to Katun 8-Ahau and Katun 6-Ahau, as follows. The Christian (AD) dates used by Roys represent the "Morley-Spinden" correlation, off by three years from the "Goodman-Martinez-Thompson" correlation. I have shown the "Goodman-Martinez-Thompson" dates to match the data of the table in the text, and added the Baktun and Katun.

Baktun.Katun	AD date	event
9.0 8-Ahau	435	a half interval
6-Ahau	455	Chichen Itza discovered
11-Ahau	534	Chichen Itza occupied (estimated)
9.13 8-Ahau	692	Chichen Itza abandoned
		Teotihuacan destroyed
4-Ahau	731	Chakanputun seized
10.6 8-Ahau	948	Chakanputun abandoned
4-Ahau	988	Chichen Itza occupied
10.19 8-Ahau	1204	Chichen Itza conquered
		Tula destroyed ca AD 1170,
4-Ahau	1244	Mayapan seized
11.12 8-Ahau	1461	Mayapan destroyed

Notice that the primary city is destroyed during each instance of Katun 8-Ahau, but that the interval, as a result, is 256 years (as Edmonson noted), not the 520 years I have found for Olmec sites and locations in the Valley of Mexico.

[\[return to text\]](#)

Note 15 --

As mentioned by Malmstrom, Walter Krickeberg, in *Mitos y leyendas de los Aztecas, Incas, Mayas, y Muiscas* (1980), states that the Nahua (Aztecs) believed that the present "world" came into being in the equivalent of our year AD 726. Malmstrom calculates the Toltec Haab calendar as starting in AD 778 (52 years later). Krickeberg also dates the actual founding of the city of Tula to the year AD 856. The Toltecs apparently took up their earliest residence at a location south of Mexico City. In the writings of Fernando de Alba Ixtlilxochitl (AD 1568 - 1648) the claim is made for the founding of Tula to AD 566.

The *Popol Vuh* Book

The *Popol Vuh* is not a metaphorical narrative. The *Popol Vuh* is history, although frequently wildly out of chronological order. Its original creation dates from circa 600 BC in Veracruz or the Valley of Mexico. Scenes from the *Popol Vuh* have been found as murals dated to the first century AD. It starts with a record dating back to perhaps 30,000 BC (or 41,000 BC), and clearly details the period between 10,900 BC and 8347 BC, eventually concluding with details of the 8th and 7th century BC. In the 16th century AD, it was recorded in a European script, in a European notebook.

If the reader has followed the outline of events as presented on these pages, it will become obvious that the *Popol Vuh* describes the "creation of the world" in the same terms as nearly all other "mythological texts" worldwide -- the series of "mythic" events established for Egypt, Mesopotamia, India, China, and many other nations.

How this could be, how peoples removed by centuries and continents could all describe the same series of incidents, not wholly matching in detail, but certainly in effect, is astounding. The *Popol Vuh* corresponds to details found in Books 10 and 11 of the Maya *Chilam Balam*,

but mostly transformed into an exciting narrative.

What is probably more interesting is that a reading of the *Popol Vuh* provides access to many obvious aspects lacking in other sources -- the initial cold rains as well as the shadowed sky of the Younger Dryas, the relationship of the southern Peratt Column and ball plasmoids to the appearance of Saturn in the north, the number of times the ball plasmoids in the south collapsed, hints at the starting date of the blazing of Venus in 685 BC, the length of time of the disappearance of the Sun and planets after the plasmoid from Jupiter hit the Sun.

Introduction

For those readers not familiar with the *Popol Vuh*, I will reproduce parts of an introduction by Suzanne D. Fisher, from another work. The following thus recaps the *Popol Vuh* in broad outline and gives some flavor of the contents. [\[note 1\]](#)

"The Popol Vuh, written in the 16th century, was discovered in the possession of the indigenous residents of the town of Santo Tomás Chuilá, today Chichicastenango, Guatemala, by Father Fray Francisco Ximénez, at the beginning of the 18th century. Ximénez translated it and included it in his historic work, but also transcribed the text into the indigenous tongue. This manuscript remained forgotten in the archives of the convent of Santo Domingo until 1854, when it was found by Dr. Carl Scherzer, who published it in Vienna in 1857. Presently it is in the Newberry Library of Chicago."

"Barrera Vásquez and Silvia Rendón, experts on Mayan writings, maintain that the naturally indigenous religious and historical texts were copied from ancient codexes, which fact is quite likely, since the quantity of events, names and exact dates contained in these documents could not have been kept entirely in the memory. ... [likewise] the Popol Vuh bears witness to the existence of an ancient book from which the narration of the origin of the world has been taken."

The *Popol Vuh* makes reference to four preexisting glyphic documents as its sources:

- **"The Council Book"**
- **"The Light that Came from Beside the Sea"**
- **"Our Place in the Shadows"**
- **"The Dawn of Life"**

What I understand as four separate titles, Tedlock sees as epithets for a single title, the **"Council Book."** But there are sufficient and expansive details in the narrative to suggest separate books for separate periods of history -- very old history. It looks, in fact, as if the above list of books is given in reverse chronological order. **"The Dawn of Life"** came before the recollection of **"Our Place in the Shadows,"** which is followed by the book of **"The Light that Came from Beside the Sea."**

Understanding the broad outline of events since the Upper Paleolithic in Europe, it becomes obvious that **"The Dawn of Life"** deals with events or conditions before 30,000 or 40,000 ya (years ago). One of the books of the *Chilam Balam* (Book 11) uses the same source. To claim a record dating to 30,000 BC might seem extravagant, but the details put forth by some pages of the *Chilam Balam* are a convincing duplication of what we know was seen in the skies during the European Aurignacian (30,000 to 28,000 ya), Gravettian (28,000 to 24,000 ya), and Magdalenian (17,000 to 14,000 ya) archaeological periods. It is clear that the *Chilam Balam* and the *Popol Vuh* use the same source material.

As I have pointed out earlier, if Europe had not been depopulated because of climatic conditions following 10,900 BC, we would hear of the experiences before that time from present inhabitants of southern Europe. These were the people who carved the first Venus Figurines, and decorated 300 caves in France and Spain.

The next book, **"Our Place in the Shadows,"** recounts the 1500-year period of darkness from 10,900 to about 9,000 BC, and the subsequent drying up of the South American jungle with the change northward of the equatorial climatic zone (after the Younger Dryas). We can be almost certain of that, for the very same suggestion is encapsulated in the very first paragraph of the *Popol Vuh* where the authors describe their intent and the structure for the narrative as:

"And here we shall take up the demonstration, revelation, and account of how things were put in shadow and brought to light by... ."

I don't think that this statement is a metaphor for some sort of revelation; not if Tedlock includes the word "account." It is followed by a list of Gods representing "Oxlahun-ti-ku," the God or God-group known as "The Thirteen" in the *Chilam Balam*. The quotation above deals with an account of how the world became dark, and how it was lighted up again due to action of "The Thirteen."

Although it is never explicitly noted in the *Popol Vuh* that at the first recorded period of

history there was light, we can surmise as much from the line:

"... how things were put in shadow and brought to light... ."

It is also never indicated "how" things were put in the shadow. It is unusual not to identify an agent for an action, and this first line almost seems to suggest itself as an introduction to the tale that follows in a manner which indicates that the following is indeed a narrative and not to be taken too seriously.

It is the following book, "**The Light that Came from Beside the Sea,**" which resolves how things were "brought to light." I have assumed here that this would recount the lighting up of Saturn in 4077 BC. But in considering the extent of the 13 Baktuns of the time period before 3147 BC, it looks possible that the "coming to light" was not the lighting up of Saturn (and the first visibility of the Sun), but the "first creation" in 10,900 BC -- the appearance of the brilliant light of the southern ball plasmoids identified by Anthony Peratt. [\[note 2\]](#)

Together with the statement about an account to be given of "how things were put in shadow and brought to light," the sequence of historic eras may reveal some of the underlying philosophy of the Maya, and by extension all of the people of Mesoamerica. Throughout the *Popol Vuh*, the Quiche tribe, other tribes, and other peoples, are called "sacrificers and penitents" in relationship to the Gods. Yet nowhere is there any indication of why people should be penitent or should have to sacrifice. It seems to be a given, as if everyone knew that this was a condition for all humans. The only thing which would make sense of this, very similar to the thinking in antiquity elsewhere, is that the humans felt responsible for the changes that had happened in the constitution of the world. Penitent for their wrongdoing, sacrifice was required to maintain the new order established by the Gods with the return of the light. [\[note 3\]](#)

The last book, the "**Council Book,**" I would suggest, is a recounting of historical events since 3147 BC, and separately in terms of the Long Count after 747 BC. Especially the last of these two records functioned also as an instrument for predicting the future. Because the larger (earlier) portion was in terms of Katuns, the cycle of 13 Katuns became the main instrument of prediction.

Suzanne Fisher continues:

"The Mayans of Guatemala (in the Popol Vuh) tell of the creation of the world in a cosmogonic myth that can be considered as the best structured and most complete. In it they express how creator gods, reunited in council, decide to create the world so that a being who venerates and supports the gods inhabits it. Once the world is organized, there are several attempts to form human beings, that correspond to the cosmic creations and destructions referred to in other myths. They speak also about a deluge, but also of burning resin, that destroys the men of wood because these were not aware of their creators. After this deluge, the gods create the man of maizemeal, the present man,

who is the conscious being who venerates and feeds the gods. In this myth, too, there is a fight of the beings of the underworld, the gods of death, with the celestial beings, Hunahpu and Ixbalanque [Xbalanque], who, after conquering death, are transformed into the sun and the moon, starting off the time of the men."

What I will do is to add annotation to summaries and occasional extracts from the excellent translation of the *Popol Vuh* by Dennis Tedlock (rev. 1996). The *Popol Vuh* consists of five books, a very sensible division made by one of the first translators. I should note, by the way, that Hunahpu and Xbalanque were not transformed into the Sun and Moon.

Although there is a clear sequence of events corresponding to historical periods stretching far into the past, the Maya, like the other people of Mesoamerica had substituted a repeating series of 13 Katuns which largely obliterated the continuity of history. I have made clear the implications of this in previous text. History was recognized as a continuum but it was disfigured by the qualities of the repeating series of 13 Katuns.

We see the continuity expressed by the fact that the *Popol Vuh* narrative definitely starts at the beginning (in Book 1, below). But the selection of events is not in order, and the authors of the *Popol Vuh* make selections from the various source books as they saw fit. This is compounded by the annoying propensity of Mesoamerican languages to disregard chronological order as really meaningful. (Annoying, that is, to Indo-European speakers.) The narrative not only frequently lists events in complete disorder, but also presents planets as different characters. One gets the feeling that the authors were reading from illustrated records with little awareness of the actual connective sequence, so that, as a notable example, Venus takes on the character of Sovereign Plumed Serpent, one of the original Gods, as well as the celestial twin Hunahpu.

The narrative, in fact, expounds the religious philosophy developed after the event of 685 BC, as it did elsewhere in the world, although it is not at all clear what this philosophy was.

Book 1: Creation of the World

This describes the initial meeting of the Gods, where it is decided to create the Earth and inhabit it with animals and humans. The stillness before creation is related, living in the shadows, the long time span, the first two attempts to make humans, and their destruction, the last by a flood. This book mixes the plasmoids of the Peratt Column in the south with planets in the north. Seven-Macaw is introduced.

The Northern Gods

What needs to be addressed here are the names and numbers of the Gods. For the *Chilam Balam* it was not difficult to come up with 13 Gods, as Book 10 of the *Chilam Balam* claims. In the *Chilam Balam* I added together the six planets of the Saturnian stack (including Venus), plus the 7 clearly visible satellites to reach 13 in number. The *Popol Vuh* will list five northern planets instead. But the *Popol Vuh* provides a list of names, together with epithets, so that it is not easy to distinguish the Gods. My best counting effort is listed below.

The *Popol Vuh* actually lists the most coherent set of names for the Gods, separating the Gods of the south from the Gods of the north, and calling the southern apparitions the "Heart of Sky, Heart of Earth" while calling the northern apparition the "Heart of Lake, Heart of Sea." Only the Gods known as the "Heart of Lake, Heart of Sea" are listed in the opening paragraphs. Since later enumerations almost always list 5 names for these, the count should be modified as shown below. I have therefore introduced some modifiers to clear up the count of Gods of the "Heart of Lake, Heart of Sea." The quoted text is a transliteration of the original, in poetic form, by Tedlock. [\[note 4\]](#)

"And here we shall take up the demonstration, revelation, and account of how things were put in the shadow and brought to light by..."

*the [1] Maker, [2] Modeler,
[also] named Bearer, Begetter,
[3] Hunahpu Possum, [4] Hunahpu Coyote,
[also called] Great White Peccary, Coati,
[5] Sovereign Plumed Serpent,
[collectively known as] Heart of Lake, Heart of Sea,
plate shaper, bowl shaper, as they are called,
also named, also described as
the midwife, matchmaker [Maker and Modeler are called]
named Xpiyacoc, Xmucane,
defender, protector,
twice a midwife, twice a matchmaker."*

Tedlock suggests that Hunahpu Possum and Hunahpu Coyote are likely epithets for the twins Hunahpu and Xbalanque, who do not appear in the list, although they will soon appear in the narrative. Sovereign Plumed Serpent is Quetzalcoatl, Kukulcan of the Maya -- Venus. The rest I cannot readily identify, although Xmucane is most likely the planet Uranus, identified as female by "her" long hair. I was initially confounded that Sovereign Plumed Serpent was included in this list, since Sovereign Plumed Serpent (Venus) should not have shown up until after the nova event (what most other peoples hold to be the "creation") of 4077 BC. That Venus was expelled at this time (in 4077 BC), and equatorially, is certain because Venus ended up orbiting the stack of planets (probably at the level of the mass centroid).

But this was resolved when I realized that Mercury should be included in the stack, positioned below Saturn and above Mars. As I have pointed out in an earlier chapter, from Upper Paleolithic sculptures it looks like this might have happened late in the Gravettian (circa 24,000 ya) or during the Magdalenian period (17,000 to 14,000 ya).

In the Magdalenian, Mercury can be identified as the second object from the bottom, and looks in some sculptures of pregnant figurines of the Magdalenian to be considerably displaced from the center of Saturn. This would suggest the later existence of a petaled form of plasma impinging on Mercury.

Very importantly, I would also suggest that Mercury had an atmosphere until recently (686 BC, in fact), for there still today exists a remnant much denser than could be possible if Mercury had been airless for billions of years. Having an atmosphere during the "Era of the Gods" would explain the shell-like array of plasma plumes connecting Mercury and Saturn, as pointed out by Talbott (who misidentifies Mercury as Venus).

From the usage of the names of the gods in the remainder of the *Popol Vuh* it is also almost certain that "Heart of Lake, Heart of Sea" is a collective name encompassing all the names and epithets.

Once it is realized that there are two sets of Gods, at opposite poles of the Earth, identification becomes much easier. The northern Gods, seen from a latitude of about 10 degrees in northern South America, would be seen to rise out of the sea ("Heart of the Sea") on a daily basis but sit in the sky surrounded by a pool of plasma ("Heart of the Lake") -- Saturn's rings. The northern Gods likely constituted, from top to bottom, Uranus, Neptune (which after 9,000 or 5,600 BC may not have been visible), Saturn, Mercury, and Mars. This adds up to five. The record of the "second creation" of Book 10 of the *Chilam Balam* does not include Neptune as visible.

[Image: A pottery Image: "Six gods and Jupiter. The text reads of an attempt to counsel Jupiter into the act of creation." After David Freidel and Linda Schele "Maya Cosmos" (1993).]

I should also note that Allen J. Christenson, in *Popol Vuh, Sacred Book of the Quiché Maya People* (2003), recognizes six Gods of the North, but based on reading "Sovereign Plumed Serpent" separately as "Sovereign" and "Quetzal Serpent." This is wholly correct if the list of six reflects conditions after 4077 BC.

That there are five gods in the north can be verified from a pot illustration presented by Freidel and Schele in *Maya Cosmos*, as I mentioned in an earlier chapter. The pot presents six gods in conference with Jupiter (God L), urging him to start creation. The six Gods have various names, of which God "Three Born Together" is obviously the three plasmoids of the south. Subtracting God "Three Born Together" leaves five gods that can be assigned to the north. [\[note 5\]](#)

The Southern Gods

The other set of Gods -- "Three Born Together" -- are collectively known as the "Heart of Sky, Heart of Earth." They are identified in the *Popol Vuh* as Thunderbolt Hurricane, Newborn Thunderbolt, and Sudden Thunderbolt. Thunderbolt Hurricane could also be translated as "one-legged thunderbolt" (Tedlock). These were the three plasmoids of the Peratt Column seen in the south since 10,900 BC, which rose out of the south horizon ("Heart of Earth") on a daily basis and rotated into the sky ("Heart of Sky"). The three southern plasmoids will act in concert repeatedly as the "Heart of Sky." At three times in the *Popol Vuh* a dialog is developed between the Gods of the north and the Gods of the south.

The Survey

The first activity of the *Popol Vuh* is the "*fourfold siding, fourfold cornering, measuring, fourfold staking*," which describes the overpassing brilliant lines of four of the electron beams of the Peratt Column (found also in the opening page of the *Chilam Balam*). Thus the history of the world here starts in circa 10,900 BC.

The survey of the heavens and Earth (after 10,900 BC) as a starting point has a certain elegance. It assumes agriculture as the basis of human society, although it becomes clear from the *Popol Vuh* that the Quiche remained hunters until very late.

The *Popol Vuh* next declares the emptiness before creation:

*"Only the sky alone is there,
the face of the Earth is not yet clear.
Only the sea alone is pooled under all the sky."*

The description is of the sky in the north, the "sea" in the south, "pooled under the sky" (which may be a singularly unique reference to the equatorial rings as a sea), and "the face of the earth" as the face of Saturn, shrouded in glow mode plasma. The "earth" everywhere else in the world in remote antiquity always described the land of the gods, the land in the sky, upper Earth.

The formlessness of the world is restated, "*... only murmurs, ripples, in the dark, in the night.*" This is the same understanding derived as the scribe of Book 11 of the *Chilam Balam* had, that all was night at the beginning of the world, in this case even before the world was created. It is a misreading, the result of a record in the book "**The Dawn of Life**" which for thousands of years never once had reference to the daylight world, or the humans who lived there.

As I have noted earlier, the complete absence of humans in these records is no different from

the celestial records drawn on the cave walls of Spain and southern France during the same period of time. Perhaps for a long time after the last of this record was made, the readers knew that this only related to what was seen in the night sky, and they knew that there was no record of the real world of plants, animals, and humans because these never changed. But at some later time this was entirely forgotten. This would certainly be true if the records of the various tribes had a single source from which they were copied. At that later time nothing could be said about the mundane world, or the existence of humans, for these never occurred in the texts. Darkness pervades the world of the *Popol Vuh* throughout all of the narrative until the Sun finally rises. This does not happen until Book 4, after 70 percent of the tale is completed.

The narrative next makes a clear distinction between some of the initial Gods:

"Only the Maker, Modeler alone, Sovereign Plumed Serpent, the Bearers, Begetters are in the water, a glittering light. They are there, they are enclosed in quetzal feathers, in blue-green."

First, this brings out an interesting fine point. Most creation myths simply reduce the time between 10,900 BC and 8347 BC (or circa 9000 BC) to a time of darkness followed eventually by a time of a chaotic swirling clouded sky. I have identified references to the darkness and the clouded skies in Book 11 of the *Chilam Balam*. If the narrative is in chronological order (which is to be doubted) then what we see here is the period after the Peratt Column, after the *"fourfold siding, fourfold cornering, measuring, fourfold staking."* In this case, rather than the Gods being obscured, they were seen -- five of them. [\[note 6\]](#)

Secondly, five gods are listed and all five of these Gods appear in a glitter of light and are (as if) "enclosed in quetzal feathers, in blue-green." Since it involves all of the planets, it clearly is a reference to what others term the "purple dawn of creation". The *Popol Vuh* does not generalize from this, but only declares, "thus the name Plumed Serpent."

Third, there clearly are five Gods, not six. The five Gods would seem to be listed in top-to-bottom order, accounted for as Uranus and Neptune above Saturn with Mercury and Mars below as the Bearers and Begetters -- with Venus absent. (But with Mercury identified as Sovereign Plumed Serpent.)

On the other hand, that the Sovereign Plumed Serpent is listed, perhaps implies that the *Popol Vuh* does not adhere to chronological order (surprise!), for in every other retelling of creation, including Book 10 and Book 11 of the *Chilam Balam*, Venus is only included in the grouping of planets after the surrounding coma, which had enveloped Saturn, disappears when Saturn lights up -- a switch from a glow mode coma -- the chaos -- to arc mode in 4077 BC. In Book 11 of the *Chilam Balam* Venus does not show up until after creation of the rings, as the dragon held by God the Father. This last agrees with what most of the Saturnian cosmologists have also assumed as the order of events -- that Venus was expelled at the time of the creation of the Saturn's rings, in 4077 BC. The phrase, "thus the name 'Plumed

Serpent'," is then perhaps a clue to the fact that Venus is not meant by "Plumed Serpent."

More important, however, is that the *Popol Vuh* makes here the distinction between the Gods of the north and the Gods of the south. "Only ... [list of five names] ... are in the water," that is, only these five are seen in the ocean (presumably) north of the original location of the Olmecs before migration to Central America. Directly following the listing of the Gods of "Heart of Sea" the Gods of the south will be listed in almost identical terms.

The *Popol Vuh* now declares, after having listed the five Gods of the "Heart of Sea":

"And of course there is the sky, and there is also the Heart of Sky. This is the name of the god, as it is spoken [as it is said to be]. Thunderbolt Hurricane comes first, the second is Newborn Thunderbolt, and the third is Sudden Thunderbolt."

There is no question from this that we are dealing with two sets of Gods, three in the south which dominated the time from 10,900 BC to 8347 BC, and five in the north (which had been seen much earlier).

In the next paragraph the Gods of "Heart of Sea," confer with the Gods of "Heart of Sky." This goes on for some paragraphs, and one gets the feeling that the authors of the *Popol Vuh* are making attempts to relate what really happened according to the ancient records, but it is considerably confused.

"So there were three of them, as Heart of Sky, who came to the Sovereign Plumed Serpent, when the dawn of life was conceived."

Note again that there are, specifically, three Gods consisting of the Heart of Sky. The northern Gods are here represented by the dominant God, Sovereign Plumed Serpent (or Sovereign Plumed Serpent is used as a collective noun, as seems to have been suggested earlier). I would suggest that what happens here is that the plasmoids in the south collapsed and suddenly moved north ("who came to the Sovereign Plumed Serpent"). It was likely seen, perhaps over a span of some days or months -- in a spectacular display. The plasmoids of the south neared and engulfed Earth, and then moved further north and simply disappeared. This travel past Earth completes the first of the three events where the ball plasmoids were generated because of the presence of Earth carbon dust in the Earth's stratosphere.

Three meetings are held. And each time the three Gods of the south visit the Gods of the north. Because of this, I think what we are seeing here is three complete collapses of the ball plasmoids. That these appeared three times was hinted at by Peratt. The three appearances of the plasmoids is also asserted by many other "mythological" tales.

The *Rig Veda* relates something of this sort, that is, the travel from the south to the north. A fish tows Manu and his seven sages north to the Himalayas to avoid the flood. The roles are

reversed here, since Manu and his seven sages are Saturn and the seven prominent satellites. This leaves the fish unidentified, except to suggest that it is probably the ball plasmoids.

To return briefly to the identification of the southern plasmoids, I should note that the opening page of Book 11 of the *Chilam Balam* identifies these three Gods as three trees or bushes, based on the looks of the nearest plasmoid, but also on the visual stringiness of 56 bundles of electrons which composed the plasmoids and overrode the physical structure. See, in this respect, especially the illustrations of the reconstructed views of the nearby plasmoid by Peratt in his second paper (or see Chapter 12, "The Peratt Column"). The trees are described as the hut of the first of the men from the south to populate the Yucatan:

"The white 'guaje', the 'ixculun' (and) the gumbo-limbo [tree] are his little hut, ... The logwood tree is the hut [lean-to] of Yaxum, the first of the men of the Cauich family."

-- Book 11, *Chilam Balam*

Seen from 10 degrees north latitude (Brazil) the treelimb-like nature of the near plasmoid would be most obvious. Seen from 20 degrees latitude north of the equator (Guatemala), the southern composite imagery would not have looked like a tree, and certainly not as a giant man in a striped garment, as was recorded in Australia, but as bulbous entities or, as I have noted elsewhere -- an opossum or a turtle.

Book 11 of the *Chilam Balam* likewise identifies the three Gods as three stones far to the south, below the South Pole, set beneath the "One Stone," Saturn in the north. "Beneath" describes that Saturn, as the starting point for the streams of electrons, appeared above the streams in the north. The south is not specifically identified, except as suggested by the geometry of being "beneath" and "in the dust at the feet." The dust very likely also represents the equatorial rings of the south. The brilliant ball plasmoids would easily shine through these, but the image would glitter or shimmer with the movement of the rings.

"And then the earth arose because of them, it was simply their word that brought it forth."

I need not point out that here, as elsewhere in the world, the "Earth" which "arose" was not where we live, but the "land" or "Paradise" above the north horizon. The *Popol Vuh* immediately returns the reference to "Earth" back to our globe, however. Note also that, like in Egyptian mythology, the creation happens because of spoken words.

The Mud People, the Wooden People

The *Popol Vuh* next launches into the creation of animals, who cannot speak and praise the Gods, and then the first two attempts to make humans, first of mud, which were simply allowed to dissolve.

After the mud people dissolve, and before the creation of the wooden people, the Gods of the south meet again with the Gods of the north:

"When Hurricane had spoken with the Sovereign Plumed Serpent, they invoked the daykeepers, diviners, and midmost seers."

This time Xpiyacoc and Xmucane are invoked, under a number of dual names, and as suggested by Hurricane. At the end of a long dialogue on methods, Plumed Serpent speaks, reprimanding the "Heart of Sky" (which includes Hurricane):

"Have shame, you up there, Heart of Sky, attempt no deception before the mouth and face of Sovereign Plumed Serpent," they said.

And so the wooden people were created and populated the Earth. The wooden people are a failure also, for *"they did not remember the Heart of Sky."*

"The Heart of Sky devised a flood for them," plus destructions by falling tar, by wild animals, and crushing by trees and rocks, where the wild animals and the trees and rocks are likely plasma discontinuities.

During the destruction of the wooden humans, which included attacks by kitchen utensils, the *Popol Vuh* states that "their hearth stones were shooting out." Tedlock illustrates this with glyphic representations of the three hearth stones, which are said to have entered the sky at some time in the past, and constitute three stars of Orion (but only one of the belt stars) in the form of a triangle enclosing M-42, looking like a central fire.

"Sometime in the past" is in dispute. Tedlock, in a note, points out that Freidel "places the event at the beginning of a new age and raising the entire sky rather than just the hearth stones." Freidel, although he may have "obscured" the dating, is correct within these parameters. The three stones in question (in the constellation Orion) are located below the Pleiades (actually slightly removed, below the tail of Taurus), and would only have become visible after the fall of the Absu, in 2349 BC, the date of the end of the "third creation." The "third creation" clearly constituted a new age, and the raising of the (southern) sky. The "flood" mentioned here in the *Popol Vuh* is probably the flood of 3147 BC, not the fall of the Absu in 2349 BC. However, I think the placement of the hearth stones took place in the era after 10,900 BC, as the three plasmoids of the south sky. The later Maya related this to the current condition of the sky and identified them as stars in the constellation Orion.

Cardona, in "Darkness and the Deep" (*Aeon V III*), quotes H. Osborne, in *South American Mythology* (1970), as:

"Some mythological cycles feature a primitive age of darkness before the existence of the sun, when human beings lived in a state of anarchy without the techniques of civilized life. Sometimes myths in this category appear to embody a confused racial

memory of a hunting and food-gathering stage. It is not uncommon for them to be associated with a tradition of the destruction of the primitive food-gathering race by a creator god and the creation of new races"

This parallels the destruction of the manikins, the wooden people, of the *Popol Vuh*. If, after the worldwide flood of 3147 BC, the survivors came to inspect coastal areas and survey the carcasses gnawed by scavengers and the remnants of villages, they might easily reach the conclusion that a previous generation of humans had been destroyed by the Gods.

Additionally, the "crushing by stones and trees" recounts the effects at the extreme edges of the gigantic compressive impulse in North America, but experienced to a lesser degree also in Central America and northern South America. The "fall of tar" can be accounted for as a sludge of rainwater and micro particles of carbon which fell as far south as Venezuela.

Seven-Macaw

The "Heart of Sky" continues to be invoked further into the narrative as a primary God, but at this point Seven-Macaw is introduced in a prelude to the next book. He sits at the top of a nance tree, and pretends, very proudly, to be the Sun and the Moon. Seven-Macaw is held to be the constellation Ursa Major by the Maya as by archaeologists. I would agree, although the description of Seven-Macaw hardly qualifies him as simply a seven star constellation.

"So be it [Seven-Macaw speaks]: my light is great. I am the walkway and am the foothold [the night light] of the people, because my eyes are of metal. My teeth just glitter with jewels, and turquoise as well, they stand out blue like the face of the sky. And this nose of mine shines white into the distance like the Moon."

"And so Seven-Macaw puffs himself up as the days and the months, though the light of the sun and moon has not yet clarified"

As Tedlock points out, Seven-Macaw, named "kakix" in the *Popol Vuh*, describes a scarlet macaw, which has a white beak.

Book 2: The Fall of Seven-Macaw

This part is seen as an interlude, for real humans have not been created yet. It describes the adventures of two hunter boys, Hunahpu and Xbalanque, who strike the plumed bird Seven-Macaw who resides on top of (what will turn out to be) the celestial tree in the north. This places the event in 3147 BC. Seven-Macaw's two giant sons, Jupiter, looking like a green mountain, and Mars, on its 300 years of destructive visits to Earth, are dispatched also. The twins Hunahpu and Xbalanque are gods, yet they have parents, described in the next book.

The Celestial Bird

The action of removing the celestial bird at the North Pole is set in July of 685 BC. The removed bird is Ursa Major. The action of the twins in accomplishing this is then moved, with Hunahpu and Xbalanque still as the actors, to 3147 BC, where the earlier celestial bird of the North Pole is actually the whole of the Saturnian polar display. Certainly Seven-Macaw is pretty, with a display of colorful plumage, pretty teeth, and metal disk around his eyes. Tedlock relates the disks to the eyepatches of scarlet macaws. Birds don't have teeth, though, but this is as likely some reference to the original text which has failed to resonate for us. Most often many of the details of the *Popol Vuh* story can be identified. Tedlock, in fact, furnishes a parallel reading in terms of Tzolkin day names, the cycles of Venus, and geography. Much of it makes sense, but some of it has other sources, which I will point out. The constructed narrative -- built around the bare facts -- has all the sense of being of long standing.

In notes by Tedlock it is revealed that Hunahpu's name could be rendered as "First Blowgunner" ("Hun Ahaw" in Yucatec, "One Lord," "First Lord," or "First Hunter") as well as having a meaning which reflects an affinity with Venus as the morning star, under the same name. All this is appropriate when it is recalled that in June and July of 685 BC, and as the "Sibylline Star Wars" document of AD 115 also relates, the two entities battling in the skies do so with "long fire-flames." Kugler described his impression as, "the light of the sun was replaced by long streams of flame crossing each other," looking, in fact, like the twins were carrying blowguns. Thus the "long fire flames" are the blowguns of the twins. Only birds were hunted with blowguns.

The name Xbalanque, as I have pointed out earlier (and also based on Tedlock's notes on this), can be understood as "Little Jaguar of the Night." Tedlock points out that the name could also be understood to mean "the sun's hidden aspect," although that just plays on the later association of the blowgunner boys with the Sun and the Moon. In Yucatec the face glyph for Xbalanque reads as, "Yax Bolon" which reads directly as "First Nine," but the "nine" head of the glyph is always shown with jaguar spots, which Tedlock understands as a pun on "balam," that is, "jaguar." Completing the glyptic literary device, this would also refer to "Bolon Dzacab," "Nine Lives," the name for Mars since remote antiquity.

This suggests that Hunahpu and Xbalanque are Venus and Mars, and this was my understanding at first. In fact, this is true for their noted appearance in 776 BC, during the celestial ballgame. Thus in 776 BC Venus and Mars play the role of the father and uncle of Hunahpu and Xbalanque, named One-Hunahpu and Seven-Hunahpu. But as likely One-Hunahpu and Seven-Hunahpu make their appearance in 762 BC when they clearly are Mars and Mercury. Only directly after 747 BC (15 years later) could the skull of One-Hunahpu be seen hung in a calabash tree.

It is always the same two twins, except in 685 BC, when Mars is away to the west of the Sun,

and it is Venus and Mercury which blaze for 40 days. The idea of twins in the sky resounds in almost every mythological record of recent antiquity of every nation, even in China and Australia.

Tedlock points out that if Hunahpu represents Venus, and Seven-Macaw is Ursa Major (both of which are correct for 685 BC), then the nance tree which Seven-Macaw feeds on, "the great tree of Seven-Macaw," is the Milky Way. In response to the twins suggesting "We could shoot him while he is at his meal," Tedlock places Ursa Major high above the pole, locates Venus yet at the horizon, and points out that nances start to ripen in June. A June evening would be the occasion for the blowgun shot.

The location of Ursa Major above the pole is not needed, as the reader will realize, for it is the displacement of Ursa Major which will be accomplished here -- in 685 BC. Also, at this date Ursa Major will not fall but will rise. Because of the latitude from which this is seen, Ursa Major is precariously close to the north horizon at, say, midnight, and it is toward the north horizon that it would thus fall as the night progressed. But the graphical rendition of this action on a pot ("the Blowgunner Pot") shows how the action of killing Seven-Macaw during his meal was to be understood: The tree grew out of the south. In fact the tree has the Witz mountain face at its base, a recollection of the Absu. Of course there is here some tree confusion. The Milky Way seems to be substituted for the tree which had earlier held up Saturn.

But clearly it is from the perspective of the south that the Blowgunner pot is to be understood. Seven-Macaw will fall but only during daylight hours; after 8am Seven-Macaw will fall toward the south. The date in June is appropriate, for it was on June 15 that Venus and Mercury start to blaze -- during daylight hours.

Tedlock notes that in the *Dresden Codex*, for the year AD 1235, "the confrontation occurs when Venus makes one last appearance as the evening star ... [with the last appearance on about] June 10th, AD 1235." This is also based on seeing Seven-Macaw climbing up the nance tree every night. This is not the correct year or the correct action.

[Image: "Done by Hun-Ahau; on 1-Ahau 3-Kankin he entered the sky, Itzam-Yeh." After David Freidel and Linda Schele "Maya Cosmos" (1993).]

By 7 pm Ursa Major is above the pole, then starts to "fall down" in the west. The tree of the Milky Way, however, is not anywhere near. It stretches across the horizon at nightfall, but stands up straight after midnight and as Ursa Major touches the horizon in its fall. By that time Venus has long disappeared below the horizon. The Milky Way, in fact, does not go through Ursa Major or the polar stars.

This reflects the efforts of both Tedlock and the Maya to come to an understanding of ancient records. It would have been perfectly reasonable for the 13th century AD *Dresden Codex* to recast the events of the remote past to match the skies as if it had been without variation since the 7th century BC.

Hunahpu shoots a pellet at Seven-Macaw, which breaks his jaw, loosening his teeth, and he falls to the ground. As Hunahpu approaches, Seven-Macaw rips off Hunahpu's arm. Shooting Seven-Macaw is marked on the pot as happening on May 28th, 3148 BC. The year is 32 years before the year of 3114 BC retrocalculated by the Olmecs or Maya as the end of a previous era, and makes no sense except to suggest that it happened in the astronomical year -3148, where I have used the BC notation for astronomical years, thus 3147 BC of my general chronology. [\[note 7\]](#)

To end up with this date (as Haab and Tzolkin dates) on a vase suggests a retrocalculation at a much later date, but based on earlier sunset locations rather than anything as concrete as a Tzolkin and Haab day combination (which were not in use yet). As I have suggested earlier, this might have been the seasonal day when the Saturnian system crashed. If so, it would mark the "return" location of the orbit of Earth after being released by Saturn -- the aphelion - and thus the summer solstice.

Rose and Vaughan in 1974 suggested that the aphelion of Earth's orbit moved 10 or 15 degrees in 685 BC. This is not the 15 degree shift in the equinox, but taken together it moves the date assigned to the solstice. This would locate the previous solstice some 25 or 30 days earlier than July 4th. This would be equivalent to 36 to 43 days on a previous calendar, partially on a calendar of 225 days. The Appendix "Celestial Mechanics" details the calculation.

This detail of shooting Seven-Macaw in the jaw is difficult to trace to known facts from the Eastern Mediterranean, India, or China, and it gets more difficult when the authors of the *Popol Vuh* include incidents from other time periods.

But the detail of Hunahpu losing his arm (torn off "at the shoulder") can be found among many sequences of the mythological events for 3147 BC, as, for example, Beowulf ripping off the arm of Grendel "at the shoulder." Grendel is Venus.

At this junction, both of the boys are located in 3147 BC as the very visible Venus and Mars. It is Hunahpu, Venus, who wields the blowgun as the plasma stream connection to Saturn. In the next moment, as Seven-Macaw (Saturn) falls (like Osiris fell on his side and died), the plasma connection between Venus and Saturn is interrupted -- Hunahpu loses his arm. About the ripped-off arm, Tedlock writes, "At this point Seven-Macaw's behavior departs from that of an actual macaw." No kidding!

Seven-Macaw, Itzam-Yeh the water wizard, has been identified as God-D, which I in turn have identified as Saturn -- although this should be obvious from the bird imagery and the perch atop a nance tree, which was probably the polar column from before 3147 BC, but became identified as the Milky Way 4000 years later. Note that the text of the pot reads, "he entered the sky, Itzam-Yeh." It was the release of Saturn from its stationary perch in the north which plunged it into the "skies" of the south.

Seven-Macaw goes home, while the boys engage two elderly tooth pullers and bone setters in their plot, Great White Peccary (Neptune) and the long-snouted Great White Coati (Uranus). Both were known from much older records (making them elderly indeed). Great White Peccary had not been seen in the last few thousand years. Both, in fact, are listed among the "Heart of Lake" Gods of Book 1. Now, in 3147 BC, as the Earth suddenly lifted its orbit toward the Sun, they were both seen again, departing from Saturn. Great White Peccary and Great White Coati, under the guise of providing a cure, pull the blue teeth of Seven-Macaw, and remove the rings from around his eyes; "the last of his metal came off."

This is an interesting detail, for if Saturn kept his jewels, eye rings, and whatever adornments until he fell in 3147 BC, that would suggest that Saturn was still in arc mode plasma discharge to the very last. Perhaps the earlier ring of 56 streamers of electrons in arc mode had stopped, but the surface of the planet was still blazing like a sun in 3147 BC. As the *Chilam Balam* reads, "then [first] it was that fire descended, then [next] the rope descended."

Eye rings are an unusual form of jewelry, and I can only imagine this as the equatorial rings of Saturn. When Earth changed the inclination of its orbit, and started climbing up toward the Sun's equatorial plane, Saturn would have been seen edge on, and the rings (eye rings?) would have disappeared. Similarly, the blue teeth can probably be equated to the inline sight of the core of plasma streamers in arc mode (headed for the planets below Saturn). That would have ceased as Saturn came under the electric field influence of Jupiter, as would otherwise certainly have happened when Saturn started to move away from the Sun. That Itzam-Yeh died is certain, for nothing is ever heard of any activity of Saturn again -- anywhere in the world.

The mention of "metal" as part of Seven-Macaw's "brilliance" and "fiery splendor" hint at the fact that the nature of his adornments is a late interpretation. Mesoamerica was a stone-age society which gained only a limited metallurgy by Aztec times.

When Seven-Macaw died, because of the removal of his grandeur, his wife, Chimalmat, also

died. Chimalmat is held to include the stars of the Ursa Minor, "shield net" in Nahuatl, as noted by Tedlock. If the pan of Ursa Major initially rotated at the pole (before 685 BC), then Ursa Minor would look like a net being cast in a semi-circle each night. I think this is a later attempt at rationalization. As likely it is Uranus, the planet with the long hair, which was visible near Saturn for thousands of years, and known in the *Chilam Balam* as the sister of Oxlahun-ti-ku, Saturn. Uranus is an unremarkable dark planet, and would likely have all but disappeared from view after losing its plasma connection to Saturn.

With Seven-Macaw and Chimalmat dead, the elderly doctors graft the arm of Hunahpu back on him, an event noted in the Bible as the return of Noah's dove with an olive branch in his mouth.

Zipacna

The boys then go to kill the two sons of Seven-Macaw, the giant Zipacna, whose name and certainly his habits (says Tedlock) are those of a cayman, and Earthquake. Without a doubt Zipacna is Jupiter, a green mountain, understood in Egypt as the green mummified body of Osiris (directly after 3147 BC). His cayman attributes will be recognized from the depiction of Jupiter in Olmec iconography dating to 685 BC, when the lower mountainous plasma plume is recorded as looking like the down-pointing head of a crocodile with open jaws. This last form will be retained into the era of the Classical Maya, although Zipacna is mostly depicted as slithering along a river's edge like a real cayman or crocodile. On the "seven Gods pot" Zipacna is shown above Jupiter.

The other son is Earthquake. "*Mountains are moved by him; the mountains, small and great, are softened by him,*" reads the *Popol Vuh*.

But before the blowgunner boys go after these two, we are told of an adventure of Zipacna and the Four Hundred Boys. The Four Hundred Boys are acknowledged to be the Pleiades, but probably could also signify the 400 stars of the south. "Four hundred" is a word for "multitude," often translated from the *Chilam Balam* as "infinite." The incident takes place in 2349 BC, the time of the fall of the Absu and the end of the "third creation," and known to us as the "flood of Noah."

The Four Hundred Boys are dragging a log for their house and ask the passing Zipacna to help them, which he does. They decide, however, to kill him, for he is too powerful. They ask him to help dig a hole for the center post and, while Zipacna is down in the hole, they cast in the center post with the purpose of killing him. Presuming Zipacna has been killed (he plays along with the trick), the Four Hundred Boys get on to preparing their fermented maguey drink, which takes three days.

"And then [on the third day] all the boys got drunk, and once they were drunk, all four hundred of those boys, they weren't feeling a thing." That is when Zipacna exploded from the

hole, where he had been hiding in a side cavity, and brought down the house on the Four Hundred Boys. The authors at this point note that the Four Hundred Boys became the Pleiades, but wonder if that is just a play on words in Quiche.

The reader will recognize a number of elements from the actual events of 2349 BC. Zipacna reappears after three days. The Four Hundred Boys are stinking of alcohol when they get killed. The blood in the sky is from their death. The Pleiades had appeared in the south sky for the first time. The center post of the house is the south polar plasma plume which appeared before Zipacna rose and was seen standing in the hole. The hole is the gap in the Absu at the time of the fall equinox.

The shock to the Earth, on the day of the fall equinox in 2349 BC, would have tilted the northern hemisphere of Earth away from the Sun. This would have moved the Absu up. The result would be to change the two mountains with the gap in between (as the Absu would look like at the time of the equinox) to the usual semicircular structure, with the Earth's shadow again representing the rounded doorway. The house of the Four Hundred Boys is visually completed with that.

And then it got "blown up" by Zipacna -- it showed again as an open gap as the Earth's axis returned to its original position. The house, mainly outlined by its doorway, now had disappeared, but the center post -- the southern plasma plume of the Earth -- stood in the center. All these elements are associated with 2349 BC, and with the worldwide celebrations of the Day of the Dead. Implied also is the fact that Zipacna next rose from the gap (appeared) in all his glory. Missing from the tale are the raging goddesses of the Eastern Mediterranean who wade in the blood of humans. But there are almost no goddesses in Maya mythology.

Next the blowgunner boys take on Zipacna. *"It's mere fish and crabs that Zipacna looks for in the waters ... going around looking for his food by day and lifting up mountains by night."* Zipacna searches the waters of the Absu. If he only lifts mountains at night then we have to conclude that not much of Jupiter and his giant lower mountain-like form was seen during daylight hours, but only at night. This is another of the rare references to the equatorial rings as a sea, or at least, as water. The inferred difference between the daytime and nighttime look of Jupiter is something which was never recorded elsewhere in the world.

The boys create an artificial crab, and place it in the overhang of a mountain. They meet a hungry Zipacna, and direct him to the giant crab. Amid various sexual innuendos the *Popol Vuh* tells of how Zipacna approaches the crab (a metaphor for "vulva") by crawling underneath -- up to his kneecaps. The mountain settles on him and he dies by turning to stone.

You will recognize the crab form with two extended claw arms, or the legs of Zipacna, as the "shen" form assumed by the coma of Jupiter when it entered the asteroid belt in about 2850 BC -- three hundred years after 3147 BC. This is the first of the two offending planets to be

disposed of by the twins.

Earthquake

The second to be tracked down is Earthquake, who prided himself of his destructions, *"I just scatter mountains, and I am the one who breaks them, in the course of the days, in the course of the light"* (which means "all the time"). Notice that if Earthquake (Mars) worked both night and day, he would have been seen both inside and outside the orbit of Earth, as I have pointed out in an earlier chapter.

Earthquake is fed a bird baked in clay (the *Popol Vuh* reads "plaster"). Together with the boys he walks east, to view a very large mountain, but Earthquake has weakened from eating the bird baked in "earth" (plaster). The boys bind him hand and foot, and bury him.

It was the God Hurricane who directed them to go east with Earthquake to look for a mountain and lure him "into sitting down." Tedlock notes that Hurricane may have meant a burial. I cannot place the mountain in the east, for it would have to be Jupiter with its extensive lower coma, but Jupiter had disappeared (in the actual proper sequence) into the asteroid belt 100 or more years before 2700 BC when Earthquake disappeared.

The removal of Earthquake to the east seems like the observation over an extended time period of the progressive rotation of the second nodal point of the orbit of Mars. Mars may have been seen crossing Earth's orbit further and further away each year, until after some years it was just a distant speck. His walk would slow, as it did when seen at a remove from Earth. "In the east" also assumes an outer orbit for Mars, so that when the Earth passed Mars it was first seen in the east. On an orbit with an aphelion much further from the Sun than Earth, it could have looked as if Mars just disappeared into the ecliptic and died. In fact, he should have disappeared in the west. The bird covered with earth may signify the pitted lower hemisphere of Mars. At any rate, note that the death of Earthquake is hardly as spectacular as that of Zipacna. Earthquake just disappears.

Book 3: The Ballgame

Here the story steps back to relate the demise of the father and uncle of Hunahpu and Xbalanque at the hands of the Gods of Xibalba, the Underworld, who had invited them to a ballgame. The severed head of One-Hunahpu, the father of Xbalanque and Hunahpu, is hung from a calabash tree.

The tree is visited by Blood Moon, daughter of one of the Xibalban Lords, and is impregnated by the severed head of One-Hunahpu. She goes to live with One-Hunahpu's mother, and bears Hunahpu and Xbalanque.

Hunahpu and Xbalanque in turn play a ballgame with the Gods of Xibalba, but trick them throughout the games. They eventually offer themselves to be sacrificed, but return magically to signal the start of creation. Although often presented as such, they do not "become" the Sun and the Moon.

One-Hunahpu and Seven-Hunahpu

The *Popol Vuh* now recounts three generations of its gods, placed in the time before the First Creation. Two of the original five Gods of the "Heart of Lake," Xpiyacoc and Xmucane, which had been listed as "the midwife" and the "matchmaker," are parents to One-Hunahpu and Seven-Hunahpu. These two will be the subject of the first part of this book. Xpiyacoc and Xmucane are probably Neptune and Uranus. Uranus is the woman, because of her long hair.

One-Hunahpu and Seven-Hunahpu I cannot place easily, although as soon as they venture into playing ball with the Lords of the Underworld, they are obviously Venus and Mars in 776 BC (could be 762 BC), using Mercury as the ball, as I have pointed out earlier, although the tradition among catastrophists is that the Moon was the ball. The interaction of Mars and the Moon, as well as an electric interaction between Venus and Mars, are established from Homeric literary sources. We have to assume that the date of 776 BC is indeed the celestial event which formed the basis for the foot races which were the first events celebrated as the Olympic Games in Greece, and may have constituted the first religiously based ballgames in Mesoamerica.

Venus and Mars can be placed near Earth in 776 BC, on the assumption of differing ellipticity of their orbits. I would still opt for Mercury playing the role of the ball, since both in 3000 to 2700 BC as well as during the period of 806 to 686 BC Mercury most likely showed up whenever Mars cruised close to Earth. See Appendix A, "Notes on Chronology," and the chapter "The Chilam Balam" for details. Mercury cannot be placed near Earth in 776 BC with an ephemeris, for Mercury radically changed its orbit in 686 BC as the result of an electric repulsive shock with Earth.

One-Monkey and One-Artisan

Before engaging in the ballgame, however, One-Hunahpu marries Egret Woman and begets two sons, One-Monkey and One-Artisan. Egret Woman is probably, again, Uranus, although perhaps not (see below). These two boys are likely to be the two large satellites of Uranus. They appear as the eye-slits of many, if not most, of the Venus figurines during and after the Upper Paleolithic, as I mentioned for an exemplary figurine at Dolni Vestonice in Moravia (see the chapter "Saturn and Archaeology").

One-Hunahpu, Seven-Hunahpu, One-Monkey, and One-Artisan play ball together, every day. A falcon, "the messenger of Hurricane," would come to watch them. This is not so difficult to place, since I have earlier assumed that Saturn's travel was as a seated bird, like the falcon seated on the name-serekhs of Egyptian pharaohs.

Another detail mentioned by the *Popol Vuh* is the death of Egret Woman, the mother of One-Monkey and One-Artisan. If Egret Woman was Uranus, then we have to guess why she disappeared. From the *Chilam Balam* might be suggested that Uranus disappeared into the flower that was Saturn. This is likely the disappearance from view as Earth moved closer to the rotational axis of Saturn. Saturn is large enough to completely cover Uranus, even though it was offset from the rotational axis of the planet stack.

But I'm not sure on this. One-Monkey and One-Artisan are later told to be living with their grandmother, Xmucane, who I have also identified as Uranus, although she is as likely to be identified with Mercury. With an atmosphere and a coma, and being much closer to Earth and in full view, Mercury is an obvious candidate for being the grandmother. Xmucane continues to play a major role in the family.

The First Ballgame

It is the ruckus of their ballplaying which arouses the Lords of the Underworld to action. The *Popol Vuh* lists their names and tasks, representing all the maladies afflicting humans. There are 9 of them, including the leaders One-Death and Seven-Death. "*What is happening on the face of the Earth? They should be summoned to play ball here.*"

One-Hunahpu and Seven-Hunahpu are playing ball at a ballcourt called "Great Hollow with Fish in the Ashes" when the Messenger Owls of the Lords of Xibalba arrive. Tedlock identifies "Great Hollow with Fish in the Ashes" as a location near Coban. That may have been a later geographical correspondence, but I would suggest a location in the night sky of the south defined by the Earth's trapezoid-shaped shadow on the equatorial rings at the time of the equinox.

The "Great Hollow" was last seen at the time of the end of the "third creation" at the fall equinox in 2349 BC. It is the view to the south and is an image which defines a flat plane

between two mountains, or a cleft mountain, and so defines the ballcourt with its inclined embankments. What had also been seen were the fish and the fire -- the nine secondary plasmoids from Jupiter, looking like catfish, and their impact at the Sun. (The Sun was also located in the "gap," since this was the time of the equinox.) The main plasmoid, seen in India and the Mediterranean as a dragon or as an angry goddess wading in blood, was not seen in Mesoamerica, as I have detailed earlier. All this information must have been recorded graphically in the source books of the authors of the *Popol Vuh* and differs as expected from the imagery of Asia and the Mediterranean region.

Tedlock suggests that the fishes and ashes possibly prefigure the incineration of Hunahpu and Xbalanque in the oven of the Lords of Xibalba, the tossing of the bone ashes into the river (the ecliptic), and the later sighting of Hunahpu and Xbalanque as catfish. That is true in that this element of prehistory from 2349 BC will be incorporated into the narrative again later.

That some location in Guatemala ended up named after this event does not surprise me. Ceremonial sites were also named after graphical elements from the books of antiquity. An example is Yaxchilan, whose "emblem glyph" (and thus its proper name) seems to be "cleft sky" -- a clear reference to the skies before the end of the "third creation" of 2349 BC.

[\[note 8\]](#)

It could be suggested that the fish (in the Great Hollow with Ashes) is the constellation or zodiac sign of the shark. This would show at night at the spring equinox as our constellation Libra, but not at night at the fall equinox, but at high noon instead. (It is clear that the Olmecs and Maya knew where unseen constellations were located in the daytime skies.) In either case Libra appears near the location of the crossing of the last equatorial ring and the ecliptic. The rapids that One-Hunahpu and Seven-Hunahpu had to cross on their way to the crossroads are likely the close grouping of Messier objects east of Libra, in Scorpio and Aquarius (M11, M17, M20, M8, M22, M6, and M7). In fact, the *Popol Vuh* tells that they passed through "Scorpion Rapids." The constellation Scorpio is directly east of and below Libra, and has the same name in Mesoamerica as in Babylon.

One-Hunahpu and Seven-Hunahpu follow the messenger owls after stashing their ball in the rafters of their mother's house. Following the owls, "... *they descended the road to Xibalba, going down over the edge of a steep slope.*" This is followed by Rustling Canyon, Gurgling Canyon, and Scorpion Rapids before they reach and cross the River of Blood and the River of Pus and reach the Crossroads. Tedlock finds a geographical sequence equivalent to the canyons (with some additional details), but switches to a celestial journey at Scorpion Rapids.

It should be obvious that the River of Blood is the remaining ring of the Absu which lasted into the current era. Likewise the River of Pus is the ecliptic, what the Chinese called the Yellow Road. The Crossroads are the same two rivers when these cross at the equinox, forming the Saint Andrew's cross. The colors associated with the four roads (the cross roads) are the traditional Maya directional colors, also mentioned in the *Chilam Balam*, and often

applied to anything which might be related to the cardinal directions. One-Hunahpu and Seven-Hunahpu will move to the west in the sky to reach the night sky or the underside of Earth.

When One-Hunahpu and Seven-Hunahpu had reached the council place of the Lords of Xibalba, they make mistakes, greeting two manikins, sitting down on a hot seat (a griddle). They are told to enter Dark House for the night, "a house with darkness alone inside." The other four houses are listed, and Tedlock notes that together with the first house these could easily be five of the 13 Maya constellations of the zodiac, under various conditions of the movement of Venus, either the 90-day disappearance after an easterly setting, or the reappearances of Venus on the repeating five-year cycle. I agree, with some reservations, but will attempt to tie some of the houses to actual locations in the sky in the five instances of a close approach of Mars during the period of 747 to 687 BC. I should also point out that the five houses which were designed to kill Hunahpu and Xbalanque may be equated to the five graves prepared for Mars at the Olmec site of La Venta -- the last of which is in the form of a giant cayman. I suspect that the earlier incident of One-Hunahpu and Seven-Hunahpu playing ball, or preparing to play ball, represents Venus and Mars in 776 BC. Both disappear after being seen near Earth.

One-Hunahpu and Seven-Hunahpu are brought a torch and two lighted cigars, and told to return them in the morning. But the next morning the torch and cigars have been used up, and the Xibalbans announce, *"This very day, your day is finished, you will die, you shall disappear."* The *Popol Vuh* continues:

"And then they were sacrificed and buried. They were buried at the Place of Ball Game Sacrifices, as it is called. The head of One-Hunahpu was cut off; only his body was buried with his younger brother."

Blood Moon

One-Hunahpu's head is placed *"in the fork of the tree that stands by the road,"* later identified as located at the Place of Ball Game Sacrifices. It is a calabash tree and bears fruit after One-Hunahpu's head is hung from the tree. It is likely that the tree by the road is a polar plasma plume, and thus One-Hunahpu's head is seen as the ball plasmoid at the end of the plume.

"By the road" implies the South Pole, for the ecliptic and equatorial were not seen in the north, and the "Place of Ball Game Sacrifices" was likely the gap in the Absu seen before 2349 BC, which has the cross section of a ballcourt with embankments on both sides. (This is also the image presented by the glyph meaning "ballcourt.")

Blood Moon, a daughter of one of the Lords, comes to visit the tree, and the skull of One-Hunahpu speaks to her, in yet another round of sexual innuendos:

"Why do you want a mere bone, a round thing in the branches of a tree?" said the head of One-Hunahpu when it spoke to the maiden. "You don't want it," she was told.

"I do want it," said the maiden.

The skull of One-Hunahpu spits in her hand and she becomes pregnant with Hunahpu and Xbalanque. Six months later the Lords notice, and after she denies her pregnancy, *"there is no man whose face I have known,"* the Lords command the Messenger Owls to take her away, sacrifice her, and bring back her heart.

"Blood Moon" is actually Saturn in remote antiquity in a red glow condition sometime after what we call creation. Her name is a play on "blood" and "moon." The severed head, likewise, now is Uranus suspended above Saturn at a time when all the Saturnian planets could still be distinguished and seen in separation with respect to each other, probably a time in the European Magdalenian period, around 17,000 ya, when the view of the Saturnian planets was elongated. Uranus would have hung at the top of the tree-like assembly. As usual, the *Popol Vuh* mixes details from events separated by tens of thousands of years.

Blood Moon talks the owls out of their task, substituting congealed croton sap for her heart. (Being clever is a prized personality trait throughout the Americas.) Blood Moon goes to live with the grandmother of One-Monkey and One-Artisan, and after being accepted by Xmucane, gives birth to the twins Hunahpu and Xbalanque. Hunahpu and Xbalanque are here most likely Venus and Mars, which show up when Saturn, initially pregnant, goes nova, *"they were born suddenly."* We can ask, how else is one born? But there was some need to point this out.

The *Popol Vuh* also states, *"They were born in the mountains, and then they came into the house."* I can't place the mountains, and much less the house, unless the mountains are a

representation of the rings of Saturn (which also might be the house). It is also possible that these are earthly mountains, the mountains of Mexico and Guatemala at a time when the Olmecs had very likely migrated to western coastal Guatemala. From this new vantage point Saturn would no longer rise out of the sea, but would rotate into the sky from beyond the local mountains.

Hunahpu and Xbalanque

I won't recall their early childhood, or their contentions with One-Monkey and One-Artisan, who are turned into long-tailed monkeys by Hunahpu and Xbalanque. The monkeys clamber up a tree *"the kind called yellow tree."* Recall from the chapter "Saturn and Archaeology" the image of three European Gravettian figurines (27,000 to 24,000 ya), each in buff or amber limestone. This is the yellow tree. If, as I have pointed out elsewhere, satellites of some of these planets orbited in a pattern which alternately took them out and back into the enclosing plasma of Uranus, they would most likely look to have long connecting tails to the plasma. Monkeys, indeed.

What stands out is a later activity, the cultivation of a patch of ground by Hunahpu and Xbalanque. They arrive with their blowguns, and set a mattock and hoe in the ground, and place an axe in a tree trunk. The gardening implements proceed to cultivate the ground by themselves while the boys go hunting. The cultivation of the patch of ground is paralleled by information of Book 10 of the *Chilam Balam* which details the First Creation:

"Then came the beating of (things) with wood and stone."

-- Book 10, *Chilam Balam*

As I have pointed out, this implies a rotation, or at least a rocking of the Saturnian polar configuration as seen from Earth -- not the rotation of the planet itself, but the rotation of Saturn about the North Pole, so that Venus, the stone, and Uranus, the wood, would also rotate. These two might easily pass for a mattock and hoe. (Book 11 of the *Chilam Balam* reverses the assignment to Venus and Uranus.)

The cleared garden, however, is put back to its original state at night by wild animals. Hunahpu and Xbalanque hide out to catch them in the act of reconstituting the weeds of the garden, but this action is never followed up on, for they catch a rat, who in return for his freedom only reveals the whereabouts of their father's rubber ball and gaming equipment among the rafters of their grandmother's house.

The Later Ballgame

One-Hunahpu and Seven-Hunahpu had been told by the Lords of Xibalba to bring their gaming equipment, but they had left it behind, stowed in their mother's house among the

rafters. The grateful rat secretly chews through the binding to release the ball.

[Image: The ballcourt markers from Copan, circa AD 700. After Freidel and Schele.]

I would equate the rafters of Xmucane's house to the crossing of the ecliptic and the remaining equatorial ring, and the hung ball as the ball plasmoid at the end of the south polar plasma plume. This equates the release of the ball with a time of the equinoxes, when they would cross to form the rafters. A set of three ballcourt markers at Copan shows balls suspended from twisted cords at the north and south markers, each hung from a tree. At the center marker a ball is in play between Hunahpu and One-Death, the latter being the chief Lord of Xibalba.

The tree of the north is labeled "Nine Successions," the tree of the south is labeled "Seven Successions." There is no question that these represent the polar plasma plumes, labeled with the number of times they made an appearance. (The records of Palenque differ by one count for the northern plasma plume which is called "north-eight-house.")

The rat, in this case, would probably be Mercury, who played the mouse in the 686 BC drama of chewing through the noose of the Sun. The sequencing of the *Popol Vuh* is here not too badly off, for the rat's release of the ball happens between the earlier ballgame of 776 BC and the events of 685 BC.

The boys take extensive measures to make sure that their grandmother does not see the ball, although mostly it goes to prove their cleverness. There is a curious inclusion in the narrative of the boys seeing a reflection of the overhead rat and the ball in their chili sauce, at which point they send out their grandmother to fetch water. The "reflection" is likely to be the other plasma plume ball plasmoid seen hanging from the tree of the north. (The rafters would only show up in the south.)

After sneaking the ball and playing equipment out of the house (why sneak?), the twins go to play ball every day at the court of their father and uncle. Of course the Lords of Xibalba are again disturbed, and send messengers to summon the boys. The messengers arrive at the house of the grandmother, who entrusts the message to a louse, who is swallowed by a toad,

who is swallowed by a snake, who is swallowed by a falcon.

The animals regurgitate each other, a pun on "recall," but the boys have to kick the toad in the rear to loosen the louse, demonstrating why toads do not have tails. They hurry home and the boys plant a maize ear each, prefiguring their future death and rebirth with the death and sprouting of the maize, and tell their mother and grandmother to watch for such signs. Tedlock relates the ceremonial action to named Tzolkin days, including the disappearance of Venus on a following day. But the maize is planted *"neither in the mountains nor where the earth is damp, but where the earth is dry, in the middle of the inside of their house."*

The Planted Maize

Tedlock and his informant Andres Xiloj suggest that the "planted" maize is stored in the attic of the house, and represents a Quiche maize ceremony, the "winel," which, however, involves four plants, not two. (However, I have mentioned earlier, from current information from NASA, that the stems of the plasma plumes would have been seen in pairs, intertwined.) Despite the recognition of a current custom and ceremony in the details of the narrative, I think the proper interpretation only becomes clear later. The maize is not planted on Earth, but in the north and south of the sky. These represent the plasma plumes which were seen directly after the Earth shock of 747 BC, when the boys first arrived in Xibalba. These plumes soon disappeared, thus signaling the death of the boys to their grandmother. But 60 years later, in 685 BC, because of the altered electric field of the Sun, the plumes reappeared, signaling the rebirth of the boys.

"And this is their grandmother, crying and calling out in front of the ears of green corn they left planted. Corn plants grew, then dried up."

"And this is when they were burned in the oven; then the corn plants grew again."

The text reads that the grandmother "deified" the ears and named them. Four names are given, suggesting a connection to the "winel" ceremonies. The first pair of the sets of names is "Middle of the House, Middle of the Harvest" and second pair are named "Bed of Earth, Living Ears of Green Corn" -- as if to imply a celestial and an earthly maize manifestation. "Middle of the Harvest" is late summer or early fall, and "Middle of the House" probably signifies the fall equinox. In parallel, "Bed of Earth" might signify a horizon location above the land.

The first use of the four names has only a comma as a separator, but the following sentences which explain why the ears are so named, refers to them in the plural, although this does not mean much in translation.

"And she named the ears Middle of the House, Middle of the Harvest, because they had planted them right in the middle of the inside of their home."

"And she further named them Bed of Earth, Living Ears of Green Corn, since the ears had been placed up above an earthen floor."

Let me point out also the dark mode polar plasma plumes discovered by NASA in April of 2009 consisted of double plumes. I had not predicted double plumes, but the duality might be a function of the intensity of the plasma. Interestingly, I had predicted the polar plumes about a year earlier, and also assumed that they would be bending into the night side of the magnetosphere and rising up about 40,000 miles (64,000 km).

The plants grew, and then wilted. The first spurt of growth follows the change in Earth's orbit in 747 BC. They grew again after Venus and Mercury went nova in June of 685 BC.

To Xibalba

Meanwhile, after planting the maize ears, the boys hurry to Xibalba.

"They went down to Xibalba, quickly going down the face of a cliff and crossed through the change of canyons [a series of canyons mentioned earlier]. They passed right through the birds -- the ones called throng birds -- and then they crossed Pus River and Blood River."

The canyons, rapids, and rivers were elucidated earlier in this text. The "throng birds" have been identified as migrating Swainson's hawks, thus placing the travel of the boys either in spring or autumn. Only spring fits with the close passages of Mars (and Mercury) during the last of February or early March of 747 BC. Mars and Mercury will constitute the first four instances of the twins in Xibalba. The last appearance will be played by Venus and Mercury. [\[note 9\]](#)

The boys reach the crossroads, which are now marked as Black, White, Red, and Green. Except for green, these are the directional colors associated with the cardinal directions noted in the *Chilam Balam* after 3147 BC, 2349 BC, and 1492 BC. The boys send a mosquito ahead to bite the Lords, and as a result learn their names. The boys enter, and, to the chagrin of the Lords, ignore the manikins, greet the Lords by their proper names, and avoid the hot seat.

They are told to enter Dark House for their first night's stay, and, like with their father and uncle, are brought two cigars and a torch, and told to return them next morning. But the boys are more clever, and substitute a macaw feather for the torch and set two fireflies at the end of the cigars.

We should reasonably be able to locate the feather and fireflies with an ephemeris program, even though both the Earth and Mars would still have been on elliptical orbits. There would be little chance of locating Mercury correctly in the skies, since, as I have explained,

Mercury changed its orbit radically in 686 BC. The problem is, we do not know when the boys entered the five houses, especially if the houses are zodiacal constellations which would take Mars and Mercury below the western horizon. It would in each case be some weeks, or perhaps months, after the first appearances of Mars and Mercury in the sky, although more likely it would be immediately.

Or not. Tedlock places the entry into the first house at 7 days after leaving their grandmother. Tedlock counts seven days from mention of a word pun on the Tzolkin dayname "Aj" and the word "Ja" -- meaning "house" -- when the twins instruct their grandmother in the planting of the maize (Tedlock, page 39). Seven days after "Aj" ("Ben" in Yucatec) is the day "Junajpu" ("Ahau" in Yucatec). Tedlock relates this, and additional day names, to the Dresden Venus tables, and to the repeating cycle of appearances of Venus, which first rises as the Morning Star on the day name "Junajpu" -- the name of the twin (Hunahpu) associated with Venus. (The pun is mostly lost on me.)

I think, however, that if we follow this course we would have to place the entry into the first house 7 days after the Earth shock of February 28th, 747 BC (March 8, 748 BC Julian), when they were commanded to appear in Xibalba. Seven days after the first day of the Long Count of, 6.0.0.0.0 11-Ahau, would fall on 6.0.0.0.7 5-Manik. This is not the Tzolkin day suggested by Tedlock. But the actors here are Mars and Mercury, not Venus and Mars.

I would otherwise agree with Tedlock, since nearly 2000 years later the events of 685 BC had been rationalized in terms of the high science of the Maya -- the Tzolkin calendar. Yet this would not have happened without solid data from the records of the past, the "**Council Book**." It is interesting that most of the concordances found by Tedlock involve the planet Venus, who definitely is one of the twins involved in the immolation of 685 BC, but not at the earlier stays of the twins in the various overnight houses.

The "**Council Book**" was started by the Olmecs after February 28, 747 BC. This accounts for the fact that, although Mars (with Mercury) passed very close to Earth a total of nine times since 806 BC, only the last five "close encounters" are listed in the "**Council Book**" and only these show up in the *Popol Vuh* -- also represented, in fact, by the five graves found at La Venta. All the archaeological indications are that La Venta ceremonial center was initially built after 747 BC.

[Image: A torch and two cigars above Mars and the setting Sun; the Pleiades as the torch, the reddish variable stars Aldebaran and Betelgeuse as the cigars. From SkyGlobe 3.6.]

I would place the appearance in the first house -- the House of Darkness -- earlier than Tedlock does, because it seems likely that the torch and the two cigars, which were kept lit in Dark House by the twins, can be found in the sky. This event is clearly described in the text as the first of the test houses. I go now, to the first instance of February 28, 747 BC (March 8, 748 BC, Julian). Mars will not be seen in the night skies, for Mars is traveling in the daytime. At the end of the day on February 28th, after the Sun sets in the west, with Mars close by, the torch and the two cigars show up directly above the setting location of the Sun. I'll suggest that the Pleiades represents the torch. Since the Maya had identified the cluster M-42 as a fire within the "three hearth stones" of Orion, it seems reasonable to suggest a fire for the Pleiades also -- another close grouping of stars.

The cigar tips might be represented by any of some five bright stars, all located above Mars and the Sun at this date. These are, from west to east: Capella, Elnath, Aldebaran, Betelgeuse, and Rigel. Interestingly, two of these, Aldebaran and Betelgeuse, are variable stars and either red or orange in color. They are also well above the equatorial, and thus unaffected by the remaining red equatorial ring, or by the shift in the location of the equatorial with respect to the dome of the stars after 685 BC.

... Bat House

When they reach Bat House (in 685 BC), the boys decide to sleep inside their blowguns, as a safeguard against Snatch Bats. It is the last house in the *Popol Vuh*, and here the "blowguns" are probably the appearance of plasma plumes at the north and south magnetic poles, the

result of the Earth's contact with Mercury in 686 BC, in the year before the nova condition of the Sun which had Venus and Mercury blazing for 40 days.

This did not involve an increase in the orbit of Earth, but certainly the plasma contact changed the electric field of Earth, and polar plasma plumes were again generated, although they were probably limited. This in turn would suggest that the balls (or flower plumes) at the end might have only appeared briefly. This is the last house before the twins will dive into the oven of the Lords of Xibalba.

The brief appearance of a terminal plasmoid shape would then explain Hunahpu sticking his head out of the blowgun to check if it is getting light yet, and losing his head to one of the Snatch Bats -- whatever those are. Thus the incident can be understood as the appearance of a ball plasmoid at the end of one of the plumes, which soon disappeared again. The boys ask Old Man Possum to delay the dawn, and work on finding a substitute for Hunahpu's head. I have covered the appeal to Possum to make the stripes and delay the dawn in the chapter "The Peratt Column."

Bat House might fall into the proper order as the last house if we recognize that four planets plus the Sun and Moon (not Jupiter) congregated at this time (685 BC) in Pisces, which is the constellation Bat (Bat House, thus) at the end of February of 685 BC. But aside from this coincidence, nothing much is defined. Except that in the following few days, the Moon escapes this cluster and races toward the east as an ephemeris program will show.

The escaping Moon is the rabbit who rolled away from the ballgame as a decoy at the request of the boys -- as if he were Hunahpu's head which was being used as the ball -- with the Lords in pursuit. This of course is another trick by the twins, which allows time to retrieve and restore Hunahpu's real head. You will recognize the Mesoamerican iconography of the rabbit of the Moon.

Bowls of Flowers

Additionally, we cannot neglect the four bowls of flowers which the Lords of Xibalba insist on as a prize before the first ballgame is played.

"What should our prize be?" asked the Xibalbans.

"It's yours for the asking," was all the boys said.

"We'll just win four bowls of flowers," said the Xibalbans.

"Very well. What kinds of flowers?" the boys asked Xibalba.

"One bowl of red petals, one bowl of white petals, one bowl of yellow petals, and one bowl of whole ones," said the Xibalbans.

The colors are of course the directional colors, except for west, which should have been black, but for which whole flowers are substituted. Now it is possible that what is meant here

is the appearance of plasma plumes at the cardinal directions with ball plasmoids (the "bowls") at the ends of the plumes and trifurcated plumes above these (the "petals"). I can readily imagine this to be the case for the north and south magnetic poles, at least directly after 747 BC, but it is difficult to imagine plumes in the east and west. As I have indicated earlier, these might have been the sun-lighted portion of the last equatorial ring seen standing almost upright (at 20 degrees north latitude) in the east and in the west. It is possible that the "bowls" at the end of the east and west spikes of the equatorial rings is nothing less than the view into the denser portion of an equatorial toroid -- the Van Allen belt, which traps ions and electrons above the equator of the Earth. In the earliest representations in Sumer these are shown as narrow waving flags surmounted by a circle. In Egypt they are the two flag standards on the Palette of Narmer with hawks on top.

There may be a much simpler solution, for the *Chilam Balam* claims the approach of Mercury, at the same time as the close passes of Mars -- the reason why the planets Mars and Mercury during these two centuries are known throughout the world as "the twins." I'll quote the relevant phrases here without comment. See the chapter "The Books of the Chilam Balam" for extensive speculation and comments on the meaning of these lines.

"With it descended Bolon Mayel [Nine Fragrances]; sweet was his mouth and the tip of his tongue. Sweet were his brains."

"Then descended the four mighty supernatural jars [or, two mighty demon bats], this was the honey of the flowers."

"Then there grew up for it the red unfolded calyx, the white unfolded calyx, the black unfolded calyx and the yellow unfolded calyx, those which were half a palm (broad) and those which were a whole palm (in breadth)."

"Then there sprang up the five-leafed flower, the five drooping (petals), the cacao (with grains like) a row of teeth, the 'ix-chabil-tok,' the little flower, 'Ix Macuil Xuchit,' the flower with the brightly colored tip, the 'laurel' flower, and the limping flower."

This cannot be either Mars or Venus, neither of which have a magnetic field, and would not support a "flower shape" above or below their poles. This is Mercury. Mercury probably comes as close to Earth as Mars did, but at a higher latitude. Here are the bowls of flowers, and although I count 9 flower types (representing the 9 appearances of Mercury of the *Chilam Balam*), only 4 would have been recorded in the "Council Book" for the period after 747 BC. The fifth time Mercury did not show; it relocated in 686 BC.

Of course the boys collect the four bowls by having cutting ants steal them during the night from the Xibalbans. Only four bowls of flowers are required. I would suggest that these might have represented prizes for the four games which are played. The first game of 748 BC (Julian) is played on Earth. The following four, 733, 718, 703, and 688 BC (all Julian), are played in Xibalba. But only three games are mentioned in the *Popol Vuh*. The boys lose one

game, play one to a draw, and win the game involving Hunahpu's head. The ball playing instances do not add up, or there is something missing here.

Into the Oven of Xibalba

After surviving the overnight stay in five houses, the Xibalbans attempt to trick the boys into jumping into their oven. But the boys respond with:

"'Watch!' they said, then they faced each other. They grabbed each other by the hands and went head first into the oven."

Following a suggestion among Tedlock's notes, the day in 685 BC when the boys faced each other, held hands, and jumped into the oven, can be found as June 15, Gregorian. It is a day when Venus and Mercury are in almost identical position to each other as are the Sun and Moon. I have supplied the details of this in earlier text. June 15 is 40 days to the ending date, July 25, when the plasmoid from Jupiter landed -- the time span is specified by the *Chilam Balam*.

The boys had requested two daykeepers to suggest to the Xibalbans that their bones be ground up and sprinkled in a river. The river, as always and elsewhere, is the ecliptic.

"The bones were ground and spilled into the river, but they didn't go far -- they just sank to the bottom of the water. They became handsome boys: they looked just the same as before when they reappeared."

"And on the fifth day they reappeared. They were seen in the water by the people. The two of them looked like catfish when their faces were seen by Xibalba. And having germinated in the waters, they appeared the day after that as two vagabonds, with rags before and rags behind, and rags all over too."

"They just sank to the bottom" -- of course. The planets may have lost their blazing looks, but they retained their shapes as star-like objects and remained on the ecliptic. Neither Venus nor Mercury was near the earth shortly after July 25, 685 BC, so they would most likely, except as noted below, have taken on their star-like shapes like today.

"On the fifth day they reappeared" -- The four-day delay is likely a spectacular blazing of the Sun, perhaps lasting four days, and certainly obscuring any planets near the Sun, both during the day and the night. The Sun must have totally disappeared, and this might initially have suggested the end of the Sun, and creation, since the three planets visually near the Sun -- Venus, Mercury, and Mars -- all disappeared from view. The five days of a missing Sun are noted elsewhere also. A number of Mesoamerican sources state that Quetzalcoatl (Venus) disappeared for four days after setting himself on fire.

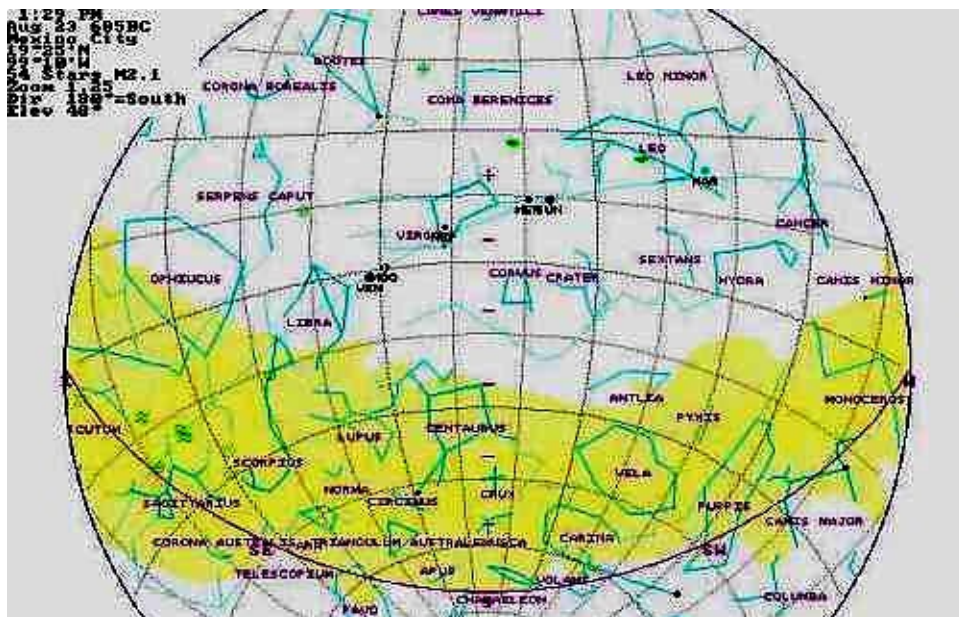

In the chapter "The Sibylline Star Wars" I wrote:

"... the plasmoid would have had a diameter of perhaps 1.5 million miles [2.4 million km]. That is twice the diameter of the Sun. The plasmoid would have engulfed the Sun. At an estimated length of 15 million miles [24 million km], the flash of the contact might have lasted 9 hours. It must have been seen all around the horizon, and the Moon [at night] would have lit up spectacularly. This describes the concluding event."

An event which would have made the Sun blaze for nine hours at a minimum, would have also taken some time to completely quiet down to the point where nearby planets could be seen again. But at that time the boys are seen as catfish, and then as covered in rags.

"[They] *looked like catfish...*" They did not. Catfish were seen, but these are more likely additional minor plasmoid bolts from Jupiter. Since these would have traveled in the ecliptic, they might easily be mistaken for Venus and Mercury, especially when it was unclear where these planets were. The catfish were seen while the day and night skies blazed with the reaction of the Sun to the initial plasmoid strike from Jupiter. Tedlock relates the catfish statement to catfish in the Great Hollow, and suggests that Xbalanque may have been a bass.

"They appeared the day after that as two vagabonds, with rags before and rags behind, and rags all over too." I would suggest, as always, that this is plasma expulsion from the two planets, remnants of the previous condition in arc mode, but now reduced to glow mode, and representing plasma plumes pointing away from the Sun and toward the Sun, and "all over too."

[Image: The Moon near Venus, the Sun near Mercury, on August 23, 685 BC, Julian (August 16, Gregorian). From SkyGlobe 3.6.]

As itinerant entertainers the boys entice the Xibalbans into asking to be sacrificed and to be brought back to life. It is done. But One-Death and Seven-Death of the Xibalbans are not

brought back to life, and with that Xibalba was defeated. The remaining vassals *"took the road to the canyon, in one single mass they filled the deep abyss,"* and they all surrendered.

Hunahpu and Xbalanque set new rules for the behavior of the remaining Xibalbans. *"Such was the beginning of their disappearance and the denial of their service."* No humans would be attacked anymore.

I have wondered a long time about the Xibalbans, but at this point it becomes clear that the *Popol Vuh* is pointing to Mars and the Maruts which had devastated the world for over 120 years. Indeed, after Hunahpu and Xbalanque went up in smoke, the equinox changed by 15 days and the aphelion of the Earth relocated and the orbit rounded soon after (Rose and Vaughan). Earth was no longer troubled by the companions of Mars.

Book 3 closes with the grandmother Xmucane rejoicing when the maize plants left behind by the twins sprout again. *"And this is when they were burned in the oven: the corn plants grew again."* We are seeing the polar plasma plumes, initially after 747 BC when the boys took off for Xibalba, and then again after 685 BC.

The boys also try to revive their uncle Seven-Hunahpu, but they fail. *"And then the boys ascended this way, here [that is, toward Earth], into the middle of the light, and they ascended straight on into the sky, and the sun belongs to one and the moon to the other."* It does not anywhere in the *Popol Vuh* say that they "turned into" the Sun and Moon, although this seems to be held as a popular uninformed reading.

The suggestion that the Sun and Moon "belong to" the twins may be from the observation (by the original Olmecs) that after the start of the blazing on June 15, Mercury moves west to the Sun and stood on the right on July 25th and continued to get closer, while the Moon, originally next to the Sun, had moved east around the sky (three times) to end up next to Venus on August 16th. At that point the Moon is separated 3 degrees from Venus, and Mercury is separated 4.5 degrees from the Sun. This is why the *Popol Vuh* noted that "the sun belongs to one and the Moon to the other." The other reason is that, as I have noted earlier, the Moon was close to the Sun when the twins first held hands and jumped into the oven.

Book 4: Tulan and the Seven Caves

Humans are created, this time from maize mash. Wandering tribes visit the Seven Caves and Tulan, the City of Reeds, where they receive their tribal Gods. The Sun still has not risen.

The Cornmeal Mountain

The Gods of the north discover how to make humans from maize meal and water. Note that the Gods of the south are no longer involved. There is a reference to the location where the

maize came from, called "Split Place, Bitter Water Place." Tedlock locates this as:

"The place in question is a high mountain just south of the Pan American Highway and near the Guatemalan border with Mexico, with a cave and a spring on its north side. Today the people of the surrounding region ... reckon it as the origin place of corn [maize]."

[Image: Izapa, Stela 5, dated 300 BC to AD 250. An enhanced version, where details are brought out with side lighting. The imagery clearly is from the "Popol Vuh." On either side of the tree are Hunahpu Possum and Great White Peccary; bottom left: Xmucane and Xpiyacoc; right bottom: Sovereign Plumed Serpent. The bottom part of the tree represents the inverted crocodile which first appeared at La Venta, and also on stela 25 at Izapa. After Jason Jones, "Middle Eastern Influence on Mesoamerican Temples" (internet, 2012).]

Perhaps the location of the origin for humans has been localized in the *Popol Vuh* or at least the source of maize has been found. The text mentions a mountain, filled with maize meal and foodstuffs. However, I am more inclined to view this piece of information as anecdotal. Stela 5, a sculpture at Izapa, dated to about 300 BC, shows the five Gods of creation extracting humans from some sort of tree and mountain. But closer inspection has revealed this to be the inverted crocodile with branches and leaves at the top -- the same image as appeared at **La Venta** in 685 BC.

The maize mountain is never mentioned again. The "seven caves" are substituted for the location of human origin, a concept held by the Toltecs and also adopted by the Aztecs. It might be suggested that the "seven caves" were added from later sources, except that the Inca also held that humanity originated from caves, localized by the Incas, as apparently do North American tribes. More on this later.

The maize meal (corn meal) used in the manufacture of humans is provided by Xmucane, the grandmother of the ballplaying twins. This places the maize-dough mountain in the era after 4077 BC.

"And then the yellow corn and white corn were ground, and Xmucane did the grinding nine times."

Andres Xiloj comments that nine grindings is excessive. Three grindings produces a fine powder. But the text is being misread here. Xmucane did not grind the same maize nine times, but on nine separate occasions ground maize. This is fully in line with the doings of Bolon Dzacab ["Nine-Lives," Mars] during the period of 4077 BC to 3147 BC. Nine times a stream of white powder extended from Saturn to Earth, and nine times Bolon Dzacab ascended the plasma stream to Saturn, leaving a mountain of corn meal in the north Atlantic (or Hudson Bay). The parallel details are given in Book 10 of the *Chilam Balam*, where it is noted that:

"Then a mass of maize-dough with the tips of corn-cobs remained here on earth."

The mountain of abundance is identified in like manner by the *Chilam Balam* as a list of foodstuffs:

"Then shoots of the yaxum tree were taken. Also Lima beans were taken with crumbled tubercles, hearts of small squash-seeds, large squash-seeds and beans, all crushed."

"He wrapped up the seeds (composing) this first Bolon Dzacab ["Nine-Lives," Mars], and went to the thirteenth heaven."

"Then a mass of maize-dough with the tips of corn-cobs remained here on earth."

This perhaps describes the pockmarked lower surface of Mars, and the nine trips upward, which in each case left behind the giant dome of water vapor clouds. The "tips of the corn-cobs," with an alternate reading of "the tips of his bones" (Bolio), are likely the fluted areas of the cloud, which are also known, I think, as "the seven caves."

The Four First Fathers

The first four people, the first fathers, were created, modeled, at this time. They were named Jaguar Quitze, Jaguar Night, Not Right Now, and Dark Jaguar. This will turn out to be a strange reading of the records of antiquity, for it soon becomes certain that the four first fathers are the four beams of electrons seen overhead in the sky.

"Perfectly they saw, perfectly they knew everything under the sky, whenever they looked."

"The moment they turned around and looked around in the sky, on the earth, everything was seen without any obstruction."

"They didn't have to walk around before they could see what was under the sky; they just stayed where they were."

"They sighted the four sides, the four corners of the sky."

Their vision was perfect, and the Gods soon realize that their sight had to be limited or they would *"become as great as gods."* Heart of Sky (the Gods of the south) marred their eyes:

"they were blinded as the face of a mirror is breathed upon. Their vision flickered."

The "flickering" is an interesting addition, for it suggests that the four electron streams turned on and off at times. These interruptions could not have been all that long, for the Olmecs didn't consider a change in the heavens until it was certain. We can surmise this from the initiation of various calendars and the determinations that an era had definitely ended. I have made note of this in prior discussion of the institution of the Tzolkin (2349 BC), the Haab (1492 BC), the modified Haab and the start of the Long Count (both at 747 BC).

This also suggests that perhaps the "placed three times" of the *Chilam Balam* happened all within the first long period. This would not be unlikely for the lack of time and sequence in this narrative.

Although the maize-mash mountain from which the first humans are derived dates from circa 4077 BC to 3147 BC, the four streaming beams of electrons, which are here equated to the first humans, are dated to the period of 10,900 to 8347 BC. They flickered says the *Popol Vuh*, but also the whole of the ball plasmoids collapsed three times.

Daniel G. Brinton, in *The Annals of the Cakchiquels* (1885), writes about the origins of the Guatemalan tribes, based on earlier researches by Francisco Antonio de Fuentes y Guzman (in the 1600s):

"Indeed, none of these affined tribes claimed to be autochthonous. All pointed to some distant land as the home of their ancestors, and religiously preserved the legends, more or less mythical, of their early wanderings until they had reached their present seats. How strong the mythical element in them is, becomes evident when we find in them the story of the first four brothers as their four primitive rulers and leaders, a myth which I have elsewhere shown prevailed extensively over the American continent, and is distinctly traceable to the adoration of the four cardinal points, and the winds from them."

The "early wanderings" are likely an identification with records of a multitude of celestial objects, not unlike those recorded in Egypt and China as part of written records, but, perhaps as likely it parallels the cave paintings of herds of animals created since 30,000 BC in southern France and in Spain. In Egypt the objects in the sky are also identified as animals. In China and Mesoamerica they are crowds of people -- migrations in progress. If these tribes had pictorial records, then an identification with the only events in antiquity which were deemed worthwhile enough to record, could easily be made. The sight of objects seen in the skies can be believed, for with the *Popol Vuh* we also have a record of the endless darkness (or shadow), the cold rains, and the lack of food (and even the fall of tar-like substance) -- which can be substantiated from archaeological and climatological records of the Younger Dryas period.

I would disagree with the "adoration of the four cardinal points." To assign the four brothers or first fathers to the four streaks of electrons passing overhead periodically, perhaps for periods of decades or hundreds of years, makes much more sense now that we have details of the Peratt column. That these four first humans or first leaders reappear in the legendary records of other Guatemalan nations only goes to prove that they all have a common source - they were seen. Brinton suggests that these nations have been in Guatemala for 2000 years, based on language differences and their own legendary records, but he could only trace ancestors back to about AD 1380.

The four first fathers received wives, who just "came into being." And people multiplied, not only the first four couples, but others also. Tribal names and lineages are recited by the *Popol Vuh*. *"There came to be many peoples in the blackness; they began to abound even before the birth of the sun and the light."* All these people were in the east. "The east" is repeated any number of times, plus the identification of "in the grasslands." [\[note 10\]](#)

If this describes the original location of the Mesoamerican people, or, more likely the Olmecs, it would represent northern South America, perhaps Venezuela ("grasslands"). The tribes of South America migrated west and north (by canoes) with the change in the latitude of the tropic and sub-tropic climatic zones after 9000 BC. Initially the climate after 10,900

BC was one of incessant rains. Then the rains stopped and the grasslands dried out. This happened in tropical South America just as it did in Africa.

The home in the east is associated with a citadel named "Tulan," the place of reeds, as well as "Zuyua," a name which has remained unidentified (except to mean "twisted" as in the linguistic use of riddles), and the "Seven Caves, Seven Canyons." This last is probably the fluted dome of water vapor seen in the far north, rising above the ocean after 4077 BC, even if it is always combined with Tulan in the *Popol Vuh*. The "Seven Caves" belongs to the genesis mythology of other American indigenous people also, not the least of which are the Incas. That it happens in North America also is the result of a repopulation of the USA from Central America and the Caribbean [\[note 11\]](#)

"Tulan," or Tollan, on the other hand, is most likely the equatorial rings in the south ("the house of bushes" in the *Chilam Balam*). From the latitude of 7 to 10 degrees in northern South America the reeds -- the equatorial rings -- would have stood up high in the sky. A migration after 7000 BC to Central America, to a latitude of 15 to 22 degrees north, would have changed the view of the rings, bringing them considerably lower in the sky. There would be no question that the "place of the reeds" had been left behind. During the year the shadow of the Earth would be placed on the rings, forming an opening into a hut or a building, defining a place left behind. [\[note 12\]](#)

Waiting for Dawn

They continue to wait for the first dawning. They pray to the "god in the sky." Heart of Sky is identified, but so are the entities in the north, with "Newborn Nanahuac" added. Tedlock points out that this is the Aztec deity Nanahuatl, "who throws a thunderbolt to open the mountain containing the first maize," where "Nanahuatl" means "warts" in Nahuatl. This clearly is Mars, seen close enough to Earth to show its pockmarked southern hemisphere. [\[note 13\]](#)

The "opening of the mountain" is referred to in Book 11 of the *Chilam Balam* as "*And its word was a measurement of grace, a spark of grace, and it broke and pierced the back of the mountains.*" This can be explained in context, quoted from the chapter "The Olmec Record of the Past" as follows:

This recounts the lowering of Mars to Earth. ... The plasma dome (or dome of water vapor) in the northeast [or north] is described as a mountain or a monument base. "Holes" are bored in the mountain, suggesting that, from the latitude of the Yucatan or Guatemala, Mars would have been seen as disappearing behind the "mountain" -- "occluded" would be better description. The holes in the mountain are the fluted areas, described earlier.

The Tribal Gods

Still waiting for the dawn, and while in the east, they hear of and go to a citadel. The citadel, here called a "mountain," is named Tulan Zuyua, Seven Caves, Seven Canyons. And here they receive their tribal gods.

"And they reached there at Tulan, all of them, countless people arrived, walking in crowds, and their gods were given out in order."

The first four fathers of the Quiche nation receive Tohil (Mars), Auilix ("Lord Swallow," Mercury), Hacauitz ("Bald Mountain," Jupiter), and Middle of the Plain. This last might be the Moon, although it is uncertain. That Tohil is Mars is without question, both etymologically (see Tedlock) and from his functions. Later Classical inscriptions assign this name to the "manikin scepter," which, although I would assign it to Venus, is identified as God K or God GII, which I have assigned to Mars. Auilix is the swallow, the bird. From Eastern Mediterranean use it would have to be Mercury.

The etymology of Hacauitz reduces to "a clear space" and "mountain" ("witz"), meaning a bald mountain. I have little doubt that this is Jupiter in his mountain form, brilliant enough to shine through the rings of the Absu, and can thus be located in a "treeless clear terrain." (There is also the suggestion that Hacauitz means "First Mountain.")

Middle of the Plain remains unidentified, but since Hacauitz shows up most notably after 2349 BC, at the same time that the Moon appears, I would guess that Middle of the Plain is indeed the Moon. Nothing more is ever said of Middle of the Plain. Further references to the Moon are to a Deer God, which, as I have already noted for Book 10 of the *Chilam Balam*, is also most likely the Moon.

What is more interesting is that in the paragraph immediately following, the gods of other tribes are listed, the Tams and Hocs. It is Tohil (Mars). The *Popol Vuh* then goes into a justification of why this was so, that is, why many tribes have Tohil as their God. Other tribes are mentioned, including "the Mexican people." Their languages changed when they left Tulan.

The assignment of the tribal Gods is placed in remote antiquity, long before Saturn lights up in 4077 BC, in the time of the "cold snap" of 10,900 BC to 9,000 BC -- the Younger Dryas. We are notified that there was no fire at Tulan, except that the Tohil tribes had fire, generated by Tohil.

There are constant complaints of the cold, and then of a great downpour (of rain and sleet). (Archaeologists have identified that the tropics received excess rains during the Younger Dryas; at least, at first.) The fires go out. The Quiche nation begs Tohil for the fire; it is given. The other tribes ask also, but are forced (by Tohil) to promise to have their hearts removed (in metaphorical language) in return for fire. They agree. This becomes the basis for future human sacrifices. [\[note 14\]](#)

There are more details in this Book. The various people leave Tulan Zuyua, still waiting for the dawn. Their travels are recorded: passing past a place called Great Hallow, a mountain called Place of Advice. *"There was nothing to eat, nothing to feed on."*

"And it isn't clear how they crossed over the sea. They crossed over as if there were no sea. They just crossed over on some stones, stones piled up in the sand. And they gave it a name: Stone Courses, Sand Banks was their name for the place where they crossed through the midst of the sea. Where the waters were divided, they crossed over."

"Where the waters were divided" describes the Absu at the time of the year near the equinoxes. Moses passed his people through the same divided waters.

They brought their Gods, Tohil, Auilix, and Hacauitz (Middle of the Plain, the Moon, is not mentioned). The tribal Gods are hidden, at the requests of the Gods. All this happens in darkness and cold. It is amazing how much of the *Popol Vuh* is given over to these descriptions.

The Dawning

And then the Sun rose. This is Saturn switching to arc mode in 4077 BC. The sequence is incorrect, however. In the *Popol Vuh* the Sun rises directly after the shadow of the Younger Dryas ended in 9000 BC. But to have a newly rising sun dispel the darkness makes narrative sense.

"The sun was like a person when he revealed himself. His face was hot, so he dried out the face of the earth."

"... when the sun had risen just a short distance he was like a person, and his heat was unbearable."

"... it is only his reflection that now remains."

The Aztecs also had a notion that the present Sun seen in the sky was only a mirrored reflection of the actual Sun. The source for this came from the same set of ancient documents. As the *Popol Vuh* claims:

"As they put in the ancient text, 'The visible Sun is not the real one.'"

The text here suggests that Earth was relatively close to Saturn initially, and distanced over the next thousand years. The "Sun," as noted, rises only part way. At this point in time the tribal Gods suddenly turned to stone, as did many of the dangerous animals.

The tribal Gods are installed in hidden locations, Auilix (Mercury) in a canyon, Hacauitz (Jupiter) on a bald mountain or red pyramid, and Tohil (Mars) in the canyon of another

mountain. The places are named as familiar localities, so that it seems that the narrative is now solidly placed in Guatemala. Interestingly, no mention has been made of Kukulcan (Quetzalcoatl), who is the earlier Sovereign Plumed Serpent, and certainly a major deity in Mesoamerica.

It is also interesting that the *Popol Vuh* at this point, now that the tribal Gods have been localized, attempts to tell us that Tohil is the same as the God of the Mexican people named "Quitزالcuat." Tedlock disputes this as an error on the part of the *Popol Vuh* authors and suggests it may be political. I agree, but it may also reflect that the authors just did not find any references to Kukulcan in their sources, yet this was a major deity of both the Aztecs (as Quetzalcoatl) and the other Maya (as Kukulcan).

A people called "Sovereign Oloman" (Sovereign Ballplayers) is mentioned again as staying behind in the east. This is likely to refer to the Olmecs (rubber people, in our naming convention), and would represent La Venta or Tres Zapotes. It is a reference to the later pilgrimage to the east undertaken by the Quiche, or actually another people who first obtained the insignias of office and the books for their own use.

At this point the translation of "east" ought to be questioned, for the cardinal direction indicated by "east" has switched a number of times from true east to north and back. This is, I suspect, the same confusion as in Egyptian mythology, where the phrase "direction where the sun rises" is always translated to "east" in rendering the records into English. The same in Greek, where "the land of the sunrise" -- Europa -- points to the northwest, not the east as seen from Greece. [\[note 15\]](#)

After the images of the tribal gods turn to stone, they still speak to the Quiche nation. They are seen in the form of young boys and, in fact, are seen bathing in the river. The river, of course, is the ecliptic. Without their earlier coma the planets became smaller visually. In the Mayan languages "small," or a diminutive prefix, is the designation for women and children (and thus for "boys" also). An enemy tribe sends two young girls, Lust Woman and Wailing Woman, to do their laundry in the river with instructions to seduce the boy-gods. Of course it is avoided through the intercession of the first four fathers.

The remainder of Book 4 is filled with tales of conquest and clever battle tactics. Some of it is reminiscent of the era of 747 to 687 BC, as, for example, in invoking four jars of bees and wasps as a weapon.

The Bundle of Flames

At the end of Book 4 the first fathers prepare to leave: "*We are going back.*" The first fathers do not die, they simply disappear, after leaving behind instructions and the wrapped "Bundle of Flames." They say, "*We are going back to our own tribal place. Again it is the time of our Lord Deer, as is reflected in the sky.*"

The reference to "Lord Deer," would place this in 2349 BC when the Moon (Lord Deer) first showed up. It makes little sense chronologically, though. Tedlock holds that "Lord Deer" is likely a day-name designation, one of the four days by which new years are known. It could thus be a metaphor for "the time has come." Tedlock also notes that the place they are returning to is not identified as Tulan, or anywhere "east," and is likely the location from which they originally came. For the first fathers, this would be the far south. They also say they are advising those who came with them "from the faraway mountains."

Jaguar Quitze leaves behind a sacred object, the "Bundle of Flames." About the "Bundle of Flames," the *Popol Vuh* reads:

"It wasn't clear just what it was; it was wound about with coverings. It was never unwrapped."

The authors of the *Popol Vuh* are here wishing to make sense of the "Bundle of Flames," which is a representation of the Jovian plasmoid of 685 BC, but they simply do not know what it is. There is a sense of the importance of this covered object because it was one of the first fathers who handed it over.

I think the indication here is that the Quiche received their religious induction quite late compared to other tribes of the Maya and the peoples of the Valley of Mexico. The authors are misreading their sources and failing to understand them. From the confusion of the narrative, in the attempt to string together a cohesive story from disparate sources, it also looks like the books were received at third hand.

The *Chilam Balam* records a much more orderly sequence of all the same events (and dated) which are likely to be from the same sources, since many of the same details are presented. (There is no mention at all of the plasmoid of Jupiter in the *Chilam Balam*, except very indirectly.) But whereas the sequencing of events in the *Chilam Balam* closely matches the chronology already established from Eastern Mediterranean sources, the *Popol Vuh* does not. Part of this might be the result of the forced attempt to create a smooth poetic narrative of the story of the ballplaying twins. Even so, there are many details which go to support my original supposition, first gleaned from the *Chilam Balam*, that the people of Mesoamerica had records dating back tens of thousands of years.

Jaguar Quitze, Jaguar Night, Not Right Now, and Dark Jaguar instruct their sons to return, *"Go see the place where we came from,"* by which is meant Tulan (Tollan), and which is accomplished in the next Book.

"The nature of their disappearance was not clear," reads the *Popol Vuh*.

I'll say! The lines of electrons simply vanished, although they may have moved north with the ball plasmoids -- something which was actually recounted from a much earlier time.

Book 5: The Quiche Nation

The second generation of Quiche make a visit to the east to obtain the insignias of chiefdom and copies of the writings of Tulan. The remainder of Book 5 deals with the political history of the Quiche in the last 500 years.

Three members of the Quiche nation go east:

"We are going east, where our fathers came from," they said."

After listing their names, Noble Two, Noble Acutec, and Noble Lord, the *Popol Vuh* reads:

"So these are the names of those who went there beside the sea."

followed by:

"... it was these same three who passed over the sea."

These are ambiguous statements, unless it is understood that "beside the sea" is meant as the other side of the sea. But the place is not identified as Tulan, Zuyua, or even as the Seven Caves.

"And then they came before the lord named Nacxit, the great lord and sole judge over a populous domain. And he was the one who gave out the signs of lordship, all the emblems."

Tedlock notes that "Lord Nacxit" is a title held by Quetzalcoatl in Nahuatl (Aztec) texts, and also that there is a Lord Nacxit mentioned in the *Chilam Balam* (Books 8 and 24) where Lord Nacxit is associated with the Itzas (who are the misidentified Toltecs).

The insignias of office include *"a canopy, a throne, a bone flute,"* and other stone-age paraphernalia, but not the "Bundle of Flames" which had been delivered by the earlier first fathers before they disappeared.

"So they came away bringing all these. Then, from beside the sea they brought back the writings of Tulan, the writings of Zuyua. They spoke of their investiture in their signs, in their words."

Tedlock points out two things. First, that "their investiture" is, literally, "that which has already entered," and, second, that the words "their signs" and "their words" refer to the characters (glyphs) of the writings of Tulan. It suggests that the three returning Quiche leaders proved that it was their destiny to assume leadership.

"When Noble Two, Noble Acutec, and Noble Lord came back, they resumed their

lordship over the tribes."

This starts to sound like Noble Two, Noble Acutec, and Noble Lord are intruders who are imposing their authority. That is not an uncommon notion among archaeologists, and clearly derives from the fact, as near as is known from the experiences of the Spanish invaders, that there were never any revolutions by the common people. But all this could have happened in remote antiquity, as can be gleaned from the fact that the *Popol Vuh* relates:

"This was when they were at Hacautiz. ... And they spent a long time there on that mountain."

Presumably "they" is the tribe, not the leaders. As I have pointed out earlier, the mountain called Hacautiz is the lower plasma outpouring of Jupiter. So the location at this point in time, when the emblems of lordship were obtained, is entirely imaginary. The trip east to obtain the "signs of lordship" would have happened before 600 BC as a pilgrimage by another tribe to La Venta by the sea. The other tribe was most likely the people of Monte Alban. But as recorded in the Books of Tulan, it would look as if the Quiche themselves had performed the trek.

The fact that the "Bundle of Flames" can be dated to 685 BC at the earliest, and, significantly, that it is not included with the listing of the insignias of office, is important in establishing the earliest date of a transmission of the Books of Tulan to other tribes in the region. What was still lacking after 685 BC, however, was a universal flux which would allow understanding the graphical books -- a script. The script was developed (as far as we currently can tell) at Monte Alban sometime after 600 BC.

Endnotes

Note 1 --

From Suzanne D. Fisher, translator of the text *Books of the Chilam Balam of Chumayel* by Antonio Mediz Bolio. [myweb.cableone.net/subru/Chilam.html]

[\[return to text\]](#)

Note 2 --

Tedlock mentions in an endnote that in an earlier edition (1985) he translated "The Light that Came from Beside the Sea," as "The Light that Came from the Other Side of the Sea," as other translators also have done. The older translation actually seems more reasonable, since this is the description of the lighting up of the southern ball plasmoids. These would appear nightly from behind (and shining through) the Absu, understood everywhere as a sea.

However, throughout the *Popol Vuh* and the *Chilam Balam* the rings of the Absu, which stood very high in the sky at 10 and 20 degrees north latitude, were never identified as an ocean. "Rivers" are mentioned in the *Chilam Balam*, however. At any rate, the light of the southern ball plasmoids would shine through the equatorial rings, since they were electrons in arc mode.

[\[return to text\]](#)

Note 3 --

The *Popol Vuh* gives a rather lame excuse for sacrificing victims of other tribes by ripping out their hearts. It involves an unspecific promise to submit to this in exchange for fire, an exchange made in remote antiquity. The whole of this looks concocted, perhaps under the influence of Christianity, for the missionaries and Spanish conquerors banned the practice everywhere.

[\[return to text\]](#)

Note 4 --

What is interesting about the diverse retellings (the *Popol Vuh* plus the Books of the *Chilam Balam*) of these phenomena is that it suggests that there were variations in the glyphic books from remote antiquity, so that perhaps separate groups of allied tribes each kept records. That in turn suggests a widespread and uniform literacy in the Americas in remote antiquity. It is as likely, however, that the diversity of the readings arose from the application of a single script, developed much later, applied with some divergence to the uniform graphical records at hand.

The authors of the *Popol Vuh* obviously read graphic depictions of events in the past, which may not have sported any text. They managed to put together a cohesive narrative from these images, with little regard for the original sequencing. We should be reminded, however, that much of this "story" preexisted among the Maya already for over fifteen hundred years -- as depicted in murals and vases. In 2009 some excavated painted murals, depicting the celestial twins in activities recalled by the *Popol Vuh*, were dated as being 2000 years old. Similarly, Stela 5 at Izapa in Guatemala (see the text), which depicts the five gods in the act of creating humans, is dated by Stirling, on the basis of its iconography, to between 300 BC and AD 250.

It was a story different from the theology of Teotihuacan which seemed to have centered on the sacrifice of Venus to save the world from destruction. The *Chilam Balam* also tells a different tale, closer to what I understand as an actual recounting of the facts.

[\[return to text\]](#)

Note 5 --

This vase is known as the 7-God pot. At the same location there is a graphically similar pot which shows 11 Gods. Adding the four large satellites of Jupiter adds up to 11. There is also

a rabbit-pot from Naranjo, where a rabbit has stolen the owl hat and clothes of God-L. God-L is Jupiter. His hat are the upper plumes, his clothes consist of the massive lower plasma outpouring. For interesting details, see www.wayeb.org/notes/wayeb_notes0030.pdf. Assuming that the rabbit is the Moon, this may be an image of the Moon after 2349 BC, identified at the Palenque inscriptions which claim that the Moon crowns herself ruler sometime after 2349 BC. It also suggests that Jupiter lost its plasma outpouring (as expected), which had been gained in 2349 BC, after the time of the appearance of the Moon. This furthermore suggests that the Moon, although it may first have been seen at close range in 2349 BC, only appeared in a regular orbit with Earth at a later date. See also www.mesoweb.com/pari/publications/rt10/creation.pdf for details.

Note 6 --

Dwardu Cardona, in "Darkness and the Deep" (*Aeon III*), writes:

"Hesiod tells us that night preceded day: 'From chaos came black night, And night in turn gave birth to day.' Other philosophical myths from Greece, reversing the process described by Hesiod, imply that darkness was first and from darkness sprang chaos. Others claimed that chaos and darkness coexisted, as, for instance, Aristophanes: 'Chaos and Night and black Erebus and wide Tartarus first existed.'"

Cardona notes that these reversals are seen in other myths also.

[\[return to text\]](#)

Note 7 --

If we go by the decorated pot from the Classical Maya era (the "Blowgunner Pot" detailed in the main text), the scene changes. Hunahpu is shown on the right of the tree, and the constellation Scorpio is shown at the base of the tree, also on the right. The constellation Scorpio has the same name (and location in the sky) in Mesoamerica as in the Mediterranean region. To the left of the tree is the constellation Rattlesnake, equivalent to Sagittarius (not shown here).

There are 13 constellations in the Mesoamerican zodiac, representing 28 days each. They are shown in the corrupted *Paris Codex*. The assignment of names to the equivalent western zodiac is still uncertain, but Scorpio and Rattlesnake (along with Fish, Peccary, Bat, Vulture, and Jaguar) are well identified.

If the constellations are correctly identified and the tree is the Milky Way, then the view is from the south horizon, not the north. We cannot see Scorpio and Rattlesnake in the north skies. The placement of Venus (Hunahpu) to the right of the tree is correct (except for the timing of the rising of the tree), for the last visibility of Venus in June of AD 1235 would be in the west, actually the northwest, but still to the right of the tree as seen standing up from

the south horizon. But this is not the date we are here concerned with. It is a date derived by Tedlock from the *Dresden Codex*, as noted in the text.

The view from the north horizon reverses the constellations if one were to follow the view of the Milky Way overhead, and would be rendered upside down with additional backward neck-craning. Only by doing the reverse, that is, by viewing the tree from the south horizon, are both the adjacent constellations and Venus placed correctly. Since the Milky Way stretches to the north (at some time of the day), the bird Ursa Major would be adjacent to the Milky Way (at some moment), although some 30 degrees removed. This also represents how Linda Schele sees the tree. In other notes (on the images at Palenque) Freidel and Schele are emphatic that Wakah-Chan, the world tree, rose in the north.

Of course, I would like to see recognition of the fact that the tree to heaven and the bird at its top appeared in the north, but especially that the tree rose from the north horizon. But this seems to have been lost to the intervening years. The actions of Hunahpu and Xbalanque have also been relegated to the mythological past. The "Blowgunner Pot" specifically states the event of blowgunning Seven-Macaw happened in what apparently is 3148 BC. The pot reads, "*He did it, Hun-Ahaw / on 1-Ahau / 3-Kankin / He entered the sky / Itzam-Yeh.*" Hun-Ahaw is Hunahpu, Itzam-Yeh is Seven-Macaw. Freidel and Schele, in a footnote of *Maya Cosmos*, suggest a translation of "Itzam" as "water wizard" and "Yeh" as "giver." They also report from other sources that in the Classic Period "Itzam" is used only with the glyph for God D, which I have elsewhere identified as Saturn.

A day of 1-Ahau 3-Kankin can be dated to -1.18.4.5.0; May 28, 3148 BC (Gregorian, August 13 correlation), as was done by archaeologists. This would be the aphelion of the Earth's orbit, which today happens at around July 4th. This is 34 years before the retrocalculated date of 3114 BC for the end of the "second creation." It is amazing that archaeologists have selected a date before 3114 BC.

The year 3148 BC probably represents the actual closing of the previous era. My estimate of the correct date of the start of the current era, based on subtracting six Baktuns of 400 solar years from 747 BC, was the year 3147 BC. Here we have a Classical Era Maya inscription, suggesting 3148 BC -- a year different if I had properly started my counting with 748 BC.

It is possible that some element of Mesoamerica knew the sunset location of the day of the release of Earth from Saturn. The Appendix "Celestial Mechanics" attempts to resolve this. [\[return to text\]](#)

Note 8 --

See Simon Martin, in "A Broken Sky: The Ancient Name of Yaxchilan as Pa' Chan" (*PARI Journal*, 2004). Martin does not identify the glyph with the "third creation," however, but he does elucidate the glyph used as the name for Yaxchilan. See also the chapter "The Day of Kan" for a discussion of the efforts of scribes at Yaxchilan to connect with the past.

[\[return to text\]](#)

Note 10 --

The *Popol Vuh* here also mentions mountain people, all speaking the same language, which may, as Tedlock notes, identify the Quiche. The reference to mountains remains. Tedlock also notes that this might be an identification of the Quiche tribes as "rustic and small in numbers by comparison with the lowland Mayans." The settlement of the lowlands, that is, the Yucatan, did not happen until about 1000 BC, however. We are here in an era dated 10,900 BC to 8347 BC (and extending to 4077 BC).

Tedlock also notes that at a later time the Quiche are described as "adorned with mere animal hides," and as hunters rather than farmers. All this applies during the Classic Era of the Maya. It may also represent the intrusion of occasional references to actual late historical conditions into the story of a mythological past which was being read from source books and was understood to represent the history of the Quiche in remote antiquity, even though in actuality it was a record of the history of another people from whom the books were obtained.

As an added note on the confusion which will surround the use of the word "east," it should be noted that a tribe known as "Oloman," a word which in Nahuatl means "ball player" (ollomani), remains behind in the east. Tedlock has another location in Guatemala in mind, but in the current context of Book 4 it is probably a reference to the Olmecs (rubber people) of La Venta, who stay behind in the east after the visiting dignitaries of Monte Alban return west with their insignias of office and copies of the sacred books -- a suggested series of events which I have already described in the chapter "The Chilam Balam."

[\[return to text\]](#)

Note 11 --

If the Olmecs came from nearer the equator (like from Ecuador), they would have had a detailed view of the southern plasmoids, unobscured by the equatorial rings. Then Zuyua, meaning "twisted," might describe the bunching of the lines of electrons at the plasmoids, and the twisting over the ball shapes. But they would have been much more impressed by the "happy face" of the nearest plasmoid.

Tedlock notes the similarity to the "Seven Caves" as a place of origins of the Toltecs or

Aztecs (the Nahua), and points to the fact that many citadels include caverns dug under the aboveground structures of the Maya. At Teotihuacan in the Valley of Mexico this includes six side chambers, looking much like the chambered barrows of western Europe. From this it might be inferred that the "Seven Caves" originally were part of a Peratt instability of the northern plasma stream after 4077 BC, and looking also like the multilobed plant depicted next to the enthroned gods of Mesopotamian seals -- rather than the mountainous vapor dome at the north horizon.

[\[return to text\]](#)

Note 12 --

Tedlock notes that the *Annals of the Cakchiquels* indicate that there are four locations of Tulan, one in Xibalba, one in the sky, and two on Earth -- in the east and in the west, which inadvertently describes a ring surrounding the whole of the Earth. The Annals also suggest that "Tulan Zuyua" of the *Popol Vuh* is the Tulan of the east, to where the tribes of the *Popol Vuh* travel to obtain their insignias. The *Annals of the Cakchiquels* is another Guatemalan document, originally dating to AD 1571, recounting the history of the Kakchikels nation, and an earlier mythology wherein the people also originated in Tulan in the east, although they originally set out from the west.

Brinton, in his introduction to the *Annals of the Cakchiquels*, writes:

"... we hear of the city of the sun god, Tulan or Tonatlan, as the place of their origin, of the land Zuiva [Zuyua] and of the Nonoalcos."

The separation of the city (Tulan) from a country (Zuyua) makes sense of the use of Zuyua both in the *Popol Vuh* and the *Chilam Balam*, although based (says Brinton) on Aztec mythology.

In fact, the *Annals of the Cakchiquels* do not use "east" and "west." The *Annals* read:

"And I shall write the sayings of our earliest fathers and ancestors, Gagavitz the name of one, Zactecauh the name of the other; and these are the sayings they spake as we came from the other side of the sea, from the land of Tulan, where we were brought forth and begotten by our mothers and our fathers, oh my children, as said of old the fathers, the ancestors, Gagavitz and Zactecauh by name, the two heroes who came from Tulan and begot us, the Xahila."

Three paragraphs later the *Annals of the Cakchiquels* reads:

"These are the sayings of Gagavitz and Zactecauh, and these are the very words which Gagavitz and Zactecauh spoke: "Four men came from Tulan; at the sunrise is one Tullan, and one is at Xibalbay, and one is at the sunset; and we came from this one at the sunset; and one is where is God."

"Therefore there are four Tulans, they say, oh our sons; from the sunsetting we came, from Tullan, from beyond the sea; and it was at Tullan that arriving we were brought forth, coming we were produced, by our mothers and our fathers, as they say."

Note that the fact that there are four Tulans is an interpretation by the narrator. As I mentioned in the text, the four locations probably describe the equatorial rings. But the city of Tulan is also obviously confused with the location of the origin of the people, the Seven Caves. It is interesting that the document locates Tulan on the "other side of the sea." *"... we came from the other side of the sea, from the land of Tulan,"* and later, *"we came to Tulan in the darkness and the night,"* and, after considerable travels, *"and departing they arrived at the place called Tapcu Oloman."* They *"took counsel there,"* and *"first unloosed our burdens."*

As I have pointed out above, "Tapcu Oloman" is the place of the ballplayer. The Kakchikels are here recounting the migration of the Olmecs as their own. The "other side of the sea" might be the Caribbean Sea between northern South America and Central America, just as it may be the whole of the Atlantic. As likely the sea may be the Pacific ocean. And yet, the sea could as well be the equatorial rings of Earth.

Just to add one more twist, "coming from the west" might simply represent the migration of the Olmecs into Veracruz, Mexico, from the Pacific coast region of Guatemala.

[\[return to text\]](#)

Note 13 --

The other name in the list which is new at this point in the *Popol Vuh* is "Falcon," although it is unclear if this is an epithet for Mars and is listed right after "Newborn Nanahuac, Sudden Nanahuac," or for Venus, whose names, "Hunahpu" and "Sovereign Plumed Serpent," follow next.

Tedlock in his glossary suggests Venus. An earlier use in the *Popol Vuh* of a falcon is the bird which would come to watch One-Hunahpu and Seven-Hunahpu at their ballgame, *"the messenger of Hurricane, Newborn Thunderbolt, Sudden Thunderbolt,"* which I suggested was the seated bird apparition seen in the skies long before 10,900 BC.

In effect this was Saturn moving north from the equatorial region, but actually was Earth falling below Saturn's equator. This would have been seen as some huge object traveling from east to west daily or nightly for thousands of years, and progressively moving further north. (See the chapter "Saturn and Archaeology.") The "Falcon" also recalls the Egyptian Falcon deity, which is equated with Horus/Mars, and is used on top of the name-serekh of the pharaoh.

[\[return to text\]](#)

Note 14 --

The same endless rains are recorded as occurring after the start of the darkness in Japanese mythology.

The lame excuse for removing hearts can only be justified by considering the dates when the *Popol Vuh* was written. It had to be an era where public opinion had turned against this practice -- after 100 or 200 years of enforced prohibition by the Spanish.

[\[return to text\]](#)

Note 15 --

Europa, "Land of the Sunrise," either points northwest to the plasma dome seen in the North Atlantic, or to the actual location where the globe of Saturn would first be seen moving up from the horizon if the rotational axes of Earth and Saturn did not line up.

-- Umberto Eco *Foucault's Pendulum* (1988)

Notes on Chronology

The information below is a collection of various observations related to chronology developed in more detail than would have been appropriate as endnotes in the main text pages.

I should also note that I rather indiscriminately mix historic and astronomical dates for antiquity and almost always list astronomical dates in BC notation. Astronomical dates are normally shown as, for example, "-747," which is the historical year "748 BC," but I often list this as "747 BC." In a few instances I quote dates from antiquity in the Julian calendar, but most times the dates refer to a backward extension of the Gregorian calendar. In a few cases, where more exactness might be called for, I have differentiated these. In all cases the dates before 747 BC are in solar years rather than an actual count of days on the Julian or Gregorian calendar. The reason for using solar years is explained in the chapter "The Maya Calendar" and also further below under Carbon-14 dating.

Additionally it should be noted that years in antiquity for the Eastern Mediterranean region differ by 4 years from actual years from Assyrian times through late Roman times (at least) and thus also differ from calculated years for China and Mesoamerica which are true to a real-time calendar. This has been known since the 19th century, but has been neglected by historians as too difficult to correct. For ephemeris calculations during this period I therefore have to select dates 4 years earlier, and sometimes five, to compensate for this error and additionally for the lack of a "year zero" among historians. Additionally, dates on antique calendars are often at variance because different nations start the year at different seasons.

Dates from Chinese antiquity calculated in the 19th century AD by western archaeologists are correct to actual "historical" solar years (and dates) if based on ephemeris information. [\[note 1\]](#)

Sources for Dates

I have kept a number of "exact" dates alive in the text, even though they are only estimates and may be inaccurate. Dates are hard to remember and recognize while reading unless they have a certain charm to them. Important dates are the following:

10,900 - 9000 BC -- The Younger Dryas

Earth, on an orbit laterally offset from Saturn, made electric contact with Saturn in 10,900 BC, causing an initial 1500 years of cold, but extending to 2500 years of shadow. This incident is discussed by Firestone, et alii, in 2001 and 2007 in two papers and a book. The initial 1500 year period represents the coldest climate the Earth has ever experienced. Large animals disappeared from the Earth. The Clovis Point culture of America ended. This was also the universal "darkness at the beginning of creation" of mythology.

The dates are from climatological records, and are for the northern hemisphere. In the southern hemisphere (which is largely tropical) the Younger Dryas ends a few hundred years earlier.

10,900 BC -- The start of the "first creation"

Earth entered the coma of Saturn in 10,900 BC. A massive compressive shock placed minute carbon particles into the stratosphere. The Peratt column developed at this time along with the southern plasmoids.

The date of 10,900 BC is thus the start of the "first creation" as can be inferred from the texts of some Maya stelae and from physical conditions. This is the "creation" noted as "the first image of the turtle." The turtle is the far southern plasmoid of the Peratt Column. The placement of the "three stones" likely represents the same objects. These are the only references to an earlier event ever represented on Maya stelae.

This date is long before the date of 3147 BC. I have used 3147 BC instead of 3114 BC after taking into consideration how the Olmecs instituted the Long Count in 747 BC.

As I have pointed out earlier, I finally realized what the Maya were talking about when they inscribed on a few stelae what they had gleaned from their books:

"And then the past epoch ended. On 4-Ahau 8-Cumku [August 13, 3114 BC], 13 Baktuns were completed."

"On 4-Ahau 8-Cumku, was (first) seen the image of the turtle."

In the philosophy of the Maya, all events cycled through periods of time, so that the event of 13.0.0.0.0 was equivalent to the event of 0.0.0.0.0 -- 5200 years earlier in 8347 BC. The date of 3114 BC for when "the epoch ended" was added to the above inscription by archaeologists.

It is confusing that two periods both ended at a count of 13 Baktuns. This is true especially to archaeologists. Only because we learn about the image of the turtle, can we jump to the conclusion that this was meant to designate the end of the "first creation" in 8347 BC.

That the predecessors of the Olmecs had kept tallies of years since before 10,900 BC, is certain from the contents of some books of the *Chilam Balam* and clear from the *Popol Vuh*. This year (10,900 BC) can also be assumed to set the date for the earliest Peratt column and the ball plasmoids of the south.

8347 BC -- End of the "first creation"

The "first creation" ended in 8347 BC when a count of 13 Baktuns was reached. The count of Baktuns had started in about 19,000 BC. The southern ball plasmoids came to an end in 8347 BC. The period after 8347 BC would be known as the "second creation." By coincidence, a total of 13 Baktuns passed before 3147 BC was reached. In 3147 BC the polar configuration came apart, and a third epoch started.

After about 9000 BC, when the effects of the Younger Dryas ended, the climate improved markedly in the northern hemisphere since the Earth's orbit was considerably below the level of Saturn and the Sun. In the northern hemisphere the Sun was higher in the sky throughout the year.

Tropical and temperate climatic zones started to move hundreds of miles north, moving the tropical wet zone to the level of the Sahara, moving the dry zone into the Mediterranean region, and improving conditions at the north polar regions.

In 4077 BC Saturn went nova and started to blaze. The coma of Saturn dropped, and Saturn and the intermediate planets Mercury and Mars were clearly seen. A plasma stream from Saturn reached to Earth.

This would have been a radical change in the celestial environment, but no notice is taken of this (as I currently understand it, except in the *Popol Vuh*). The last 1000 years of this period is what we call the "Era of the Gods."

3147 BC -- end of the "second creation," end of the "Era of the Gods," the world flood

I originally used 3114 BC as the date for the end of the "Era of the Gods" because it was a well-known date derived by retrocalculation from the Maya Long Count calendar -- even though it is based on the projection of our current Gregorian year into remote antiquity, and would thus be incorrect by 34 years. I have changed this in favor for **3147 BC**, a value correct in terms of solar years. It is based on subtracting 6 Baktuns (400 year periods) from the date of the inception of the Long Count in Mesoamerica on February 28, 747 BC (-747), which is listed as 6.0.0.0.0 in Long Count notation.

The date of 3147 BC (or, for that matter, 3114 BC) more or less matches the start of eras elsewhere, as in India. It predates the first Egyptian dynasty by 50 to 100 years. It also coincides with a marked lapse in cultural development in Northern Mesopotamia, and it predates the first kings of Kish in Mesopotamia (as developed below). Additionally it seems to mark a change in climate worldwide, today called the Hypsithermal.

2349 BC -- The end of the "third creation," the "flood of Noah."

The date is from the chronology developed by Bishop Ussher, in *The Annals of The World* (in AD 1650), and represents the date he assigned to the flood of Noah, even if there was no flood, or Noah. The date is convenient in that it is well known among Bible chronologists. The date also matches, within a decade or so, the chronology of China (as developed by the Han dynasty in about AD 200). The brief records of Mesoamerica as reported in the *Chilam Balam* are not accurate on this, however, although the reason for this is easy to find.

Events and celestial manifestations for the date of 2349 BC (or something close to it) certainly match across all continents, all in terms of a giant plasmoid (a "dragon") arriving from Venus, seen and recorded in turn by India, the Middle East, Egypt, Mesoamerica, and China.

The worldwide assignment of the culmination of the Pleiades to mark the remembrance of this event in early September, when Jupiter made a sudden reappearance on the third day, also depends on this date.

There are, in fact, four electric additional contacts by Venus during this period of 2349 BC to 2193 BC, 52 Solar years apart. The last, of 2193 BC, brought a 200-year climatic downturn to Mesopotamia and Egypt. This last event is fairly well dated from archaeological sources, and thus validates "2349 BC" if the 52-year intervals hold also. The number of so-called contacts or near contacts with Venus can be surmised from Egyptian and Mesoamerican sources -- some only depicted graphically.

1492 BC -- Exodus of Moses, Typhon

The date is from Immanuel Velikovsky, in *Worlds in Collision* (1950), and is verified from numerous medieval chronographers to within a year or two (and even by Josephus

in AD 100). Moses can be placed to the time of the 12th Egyptian dynasty if the one "Sothic date" for Senusret III is dropped as a total fiction. The event of 1492 BC shows up assigned to the proper Katun (20-Tun-year period) in the *Chilam Balam*. Egypt's Middle Kingdom came to a sudden end, Indian civilization seemed to disappear, China's Shang dynasty stopped recording history for a hundred years and relocated its capital. Mesoamerica has the same complaint as the Bible of "walking in darkness" or under a heavy overcast for 40 years or for a generation.

The occasion gave rise to the "myth of Typhon." A second, lesser, interaction happened 50 (not 52) years later, 1442 BC. The Sun stood still for Joshua. The periodic interactions with Venus had changed.

747 BC, February 27th -- Change in the Calendar, Mars

The date of 747 BC (actually -747) is also originally from Velikovsky in 1950, and verified by such diverse sources as the start of the *Babylonian Chronicle* by Nabonassar on February 27, 747 BC. Known as the "Era of Nabonassar" this chronology was promoted by Ptolemy in about AD 150 as a means of record keeping for celestial events, and remained in use to about AD 1600. The Romans rationalized their calendar on February 28th. The Olmecs started the "Long Count" on February 28, 747 BC, and added 5 days to the 360-day Haab year (for the purpose of the Long Count, 360-day years continued to be used for the past). The number of nations who had a 360-day calendar in use before 747 BC is extensive.

There were a total of nine "close calls" by Mars during this period, from 806 BC through 687 BC. This was first hinted at by Velikovsky, and asserted by Patten and Windsor (although I disagree with some of their dates and with their mechanics). It is also certified by Olmec records -- although in their strangely curious way of naming planets with a numeric prefix. Mars would have appeared inside Earth's orbit at 15-year intervals. A graphical ephemeris program -- a luxury tool not available to researchers in the 19th century and most of the 20th century -- will show that this could happen (but of course showing Mars outside the Earth's orbit). Mars would show up inside Earth's orbit if the orbital eccentricity changed -- which does not change a planet's period.

An incident in 686 BC also produced an Earth shock. Velikovsky (and Patten and Windsor) had trouble attributing this event to Mars, and could not determine the correct date. An ephemeris program will show that it was caused by Mercury -- as verified by Plutarch in about AD 200. The date, in fact, can be obtained also from two Chinese records as March 23. The ephemeris, which even if it cannot be entirely correct for Mercury at this particular time, places Mercury in line with the Sun to within 1.1 degree in azimuth and 0.1 degrees in altitude on March 20.

685 BC -- Change in the axis, a bolt from Jupiter, fall of Phaethon

The year of 685 BC was found directly from the graphical ephemeris program by matching the description of *The Sibylline Star Wars* document of circa AD 150. Initially I had no clues other than the analysis made by Franz Xavier Kugler in 1927.

To find the *year* I matched the Mesopotamian *Venus Tablets of Ammizaduga*, which describe the event, against the political activities of Assyria and Babylon during those years. Thus I closed in on 684 or 685 BC. This event is the "myth" of Phaethon, who, as Mercury (also mentioned by Hesiod), was struck by a thunderbolt coming from Jupiter, which actually was destined for the Sun. Travel of the plasmoid lightning bolt was seen and recorded worldwide.

specific seasonal dates for 2349 BC, 1492 BC, 747 BC, 685 BC

Specific dates were found from site alignments in Mesoamerica, and for the year 685 BC from the *Chilam Balam*. I looked at 13 Olmec and Valley of Mexico sites and found over 70 instances of six alignments which remained the same from site to site and determined the setting location of the Sun by date (plus the setting of the Pleiades). Sorting through these and comparing them to approximate dates and hints from other sources it quickly became obvious that these represented the event dates for 2349 BC, 1492 BC, and 747 BC. Although the year dates I have listed will in some instances be estimates, the seasonal dates are accurate.

For the event of 685 BC the actual dates in the months of June and July can be found, based on a hint from the Quiche *Popol Vuh*. A breakthrough came from a closer look at time spans (four of them plus an equivalent Julian-year date!) listed in the Maya *Chilam Balam*. This information resulted in concrete seasonal dates: the date on which Venus and Mercury started to blaze in the skies in June, the date of the release of a 15-million-mile-long (24-million-km-long) lightning bolt (plasmoid) from Jupiter, and the date of its arrival at the Sun in July. These last three also allowed tracing the actual events recorded in *The Sibylline Star Wars* document. From an Australian Aboriginal myth we can determine the arrival time of the plasmoid to within two hours, and closer yet from *Beowulf*.

The Kings Before the Flood

The earliest portions of the Sumerian *King List* probably date from shortly after 2700 BC. Our copies were transcribed from earlier sources sometime after 2000 BC and did not come to light until after AD 1900. A conforming copy of the *King List*, however, was extant in Greece since about 280 BC, having been brought from Babylon to Greece and was quoted subsequently by Greek authors. The record was at that time already 2500 years old. The Sumerian *King List* has clear parallels in the Bible and in Egyptian records, and less so in Chinese and Vedic mythology, all of which are addressed in the section "Parallel Histories," below.

The first section of the *King List* deals with the "kings before the flood" and is the oldest historical document in the world. (Sections of the Maya *Chilam Balam* recall earlier times, however.) Despite its peculiarities, it should not be neglected. The main question has always been, why the long rule lengths? The large numbers for the rule lengths of the "kings before the flood" are derived from the Sumerian use of the symbol "sar" which has steadfastly been reported since Greek times as representing "3600" -- supposedly 3600 years. A "sar" does have the value of 3600 in Sumerian enumeration, but it does not necessarily mean a "year." As noted elsewhere, a "sar" also means "turn" or "day." [\[note 2\]](#)

In Assyrian times (after 800 BC), the calendar of 360 days uses a "sarus" to represent a decade (what we would call 10 years), where a "sarus" is identified as 3600 days. The fact that a "sarus" was still in use in Assyria in the 8th century BC, and meant 3600 *days*, not *years*, is good reason to suggest that the list of the "kings before the flood" is recorded in *days*, not *years*.

The "turns" of the list for the "kings before the flood" are probably tallies in days, possibly retrocalculated from "years" by the original chronicler. If the first recorded tabulation dates from shortly after 3100 BC, the chronicler would have been aware of the change in the length of the Solar year, and might have sought accuracy by converting the tallies from years to days. Except for the use of whole numbers, the record is also consistent with the Sumerian practice of enumerating lists of products for taxation or trade in the smallest quantities even if these amounts ran into the tens of thousands, suggesting that the "sars" are the smallest unit available, days. Only the sub-totals and totals were calculated in larger units -- in units of 10, 60, 100, 360, 600, and 3600. [\[note 3\]](#)

The whole idea of even suggesting that the length of the year could have changed in the past, comes from the solidly established changes seen in the 8th century BC, when worldwide calendars of 360 days were superseded by calendars of 365 days plus one quarter day. Earlier changes in the calendar are noted from Egyptian sources (during the Hyksos period), and in Exodus, and this would suggest that the orbit of Earth had changed incrementally a number of times. Earlier yet we have the "mythological" records of Yao (in China) and Marduk (in Babylon) who both established the calendar after 2349 BC. The *Chilam Balam* makes the same claim.

There is only a limited number of days-per-year which can be used to resolve the large whole numbers of the turn counts of the "kings before the flood." These have to represent orbits closer to the Sun than our present orbit of one AU. A 225-day year makes the counts come out even. This is almost exactly the present orbit of Venus -- at 0.72 AU. In Appendix B, "Celestial Mechanics," I will suggest that 0.72 AU is an average for an elliptical orbit of Earth with perihelion at 0.54 AU and aphelion at 0.9 AU.

Lastly, let me again point out that I am using solar years -- revolutions of Earth around the Sun. Time spans in years of our current value of 365.24 days per year are of no interest, and inappropriate, since we are dealing with much shorter years. The solar year dates we are

dealing with here will actually correspond closely to corrected radio-carbon dates, which are inadvertently adjusted to solar years with the calibration from tree-ring series (details further below).

The record of the "kings before the flood" seems to reflect relocations in the strike point of the arc in the north Atlantic as the relocations of kingship to different cities. None of the five "cities" listed for the "kings before the flood" have ever been located. Each of the named "cities" looked from afar like a walled city, although in reality consisting of an immense dome of plasma (or water vapor) rising some thousand miles or more above the Earth. This is also identified as the "world mountain" as far away as China.

Kings Before the Flood from the King List					
King	City	sars	rule in 'turns'	years 225d/y	intervals of 32
Alorus	Heaven	45	162,000	720 y	
1 Alulim	Eridug	8	28,800	128	4
2 Alaljar	Eridug	10	36,000	160	5
3 Enmenluana	Bad-Tibira	12	43,200	192	6
4 Enmengalana	Bad-Tibira	8	28,800	128	4
5 Dumuzid	Bad-Tibira	10	36,000	160	5
6 Ensipadzidana	Larag	8	28,800	128	4
7 Ermendurana	Zimbir	6+	21,600*	96	3
8 UbaraTutu	Curuppag	5+	18,000*	80	2.5
	on Earth		241,200	1072	33.5
	grand total		403,200	1792	
* - corrected for a transpositional error of 600 (noted by others). -- L.C. Geerts, http://www.earth-history.com					

China (actually, Mongolia) is only slightly further than Mesopotamia from the actual location of the plasma dome in the North Atlantic. Some Mesopotamian sources identify the walls of the "cities" as a "cloud bank lowered from Heaven." Why *new* kings take up a reign at the same cities is unclear. Just as curious are the extended spans of time which run to over a hundred years, although to take a long time for Mars to slowly recede from Saturn would be expected. That the lowering of Mars was the result of a tilted orbit is unlikely, for in that event Mars would have lowered a thousand times. Even the Vedas do not suggest "a thousand times," but propose that Mars lowered "100 times," where "100 times" likely means "frequently." [\[note 4\]](#)

Interestingly, the 225-day year counts (see the tabulation above) are multiples of 32 years, except the first ("Alorus in Heaven"), and the last (which is 2 1/2 multiples). There are other indications that "32" was of some importance. A count of 32 is still used today in finger counting in Pakistan, and represents two hands worth of knuckle counts. I will get back to this further below.

It should be noted that if we look at the city names and the associated Gods, the list starts to look like an element-by-element description of the Saturnian polar configuration. Eridug is the "good city" -- the cloud bank at the horizon. The remaining names describe the rest of the apparition: the plasma stalk, its tree-like connection at the top, the sun god Utu, the field of grain within the disk. [\[note 5\]](#)

In summary, what I have used from the list of "the kings before the flood" is, first of all, the total period when Saturn stood in the sky -- 1792 years, which spans the era from circa 4939 BC to 3147 BC (this includes the 700-year lifetime of Alorus).

Secondly, I have used the start of the eight kings as the date when Saturn went nova, **3147 + 1072 = 4219**. (Revised to 4077 BC below). Besides for some well-defined changes in climate worldwide, these are the only hints from remote antiquity that we have for these important dates.

However, to this can be added the date of creation based on the death of Adam, as Saturn, in 3147 BC, and who, with a life span of 930 years, would have been born in **4077 BC** (as calculated by Josephus).

Since the eight kings show up in the mythology of other nations (in the case of the Bible with nearly identical proportional span of time), I am assuming that there is validity to the analysis performed here. I should note that in some instances the kings before the flood count as nine. This includes the number of kings given by Berossus, a listing in the *Dynastic Chronicle* of Babylonia. The name for Mars listed in the *Chilam Balam*, "Bolon Dzacab," means "nine appearances," but this may be a name for Mars after 806 BC.

Kings After the Flood

The list of "kings after the flood" is a composite of lists at various cities of Sumer, at times overlapping each other. It starts with the city of Kish, followed by Uruk (Erech). The first complete *King List* was (apparently) compiled during the Isin Dynasty (2017-1794 BC). Some 18 additional fragments and copies have been found at Nippur, Larsa, and other locations.

Copies are at times divergent, but the sum of the reign lengths given at the end of each city always add up to the same number. An exception is the grand total for the first list -- the kings of Kish -- which exceeds any possible combination of reign lengths by some 6500 "years." More on this below.

Literary analysis has shown that both the "kings before the flood" and the last part of the "kings after the flood" were added to other extant lists, and that the presumption of the passage of kingship from one city to another was retained despite a contemporary knowledge in antiquity of the overlap of dynasties.

The reason for looking at the "kings after the flood" is to verify through yet another source that 3147 BC is a valid (or reasonable) terminal date for the "Era of the Gods" and a starting date for subsequent history. Thus if the sum total of reigns of the "kings after the flood" can be fit between 3147 BC and some archaeologically determined dates, then the *King List* could be trusted to represent 3147 BC as a valid starting point. The starting date of 3147 BC

is from the "zero date" of the Mesoamerican Long Count calendar, but corrected as noted above. The Mesoamerican records reflect Tun years, which can readily be equated with solar years. How accurate the Mesoamerican records of the past is, can be gleaned from Book 10 of the Maya *Chilam Balam* books. This correctly dates every catastrophic event of the past to the correct Katun period -- except one -- thus establishing a correspondence to known or derived dates of the Eastern Mediterranean chronology.

Considering that the *Chilam Balam* records were recopied in the 16th century AD from bark books dating back perhaps as far as 2200 years earlier (to 747 BC), it is remarkable how accurate they are and astounding that the Maya had inherited from the Olmecs the world's most accurate and extensive chronology of the remote past. (Any similar records in the Valley of Mexico were destroyed by the Aztecs.)

As a later date to check against the "kings after the flood," I will use Gilgamesh, the fifth king of Uruk, who is confidently dated to 2750 or 2700 BC, even if his actual existence is somewhat in doubt because his doings have been expanded to legendary heroics. It can be shown that the sequence of kings for the cities of Kish and Uruk, if correctly read, spans the time period of approximately 400 years from 3147 BC to 2750 BC.

Similarly, this test can be done in reverse. If the date for Gilgamesh is held to be accurate, does the *King List* extend backwards from the time of Gilgamesh to reach 3147 BC as a starting point? As presented below, the sum of the individual reign lengths actually does not, missing 3147 BC by about 150 years. But there are clear reasons for that. However, the grand total for the first dynasty of Kish, which seems unrelated to the sum of the individual reign lengths, does reach back to 3147 BC. More on this further below.

Another element I am looking to verify is the Egyptian claim that the lifetime of Horus was 300 years (from the Turin Papyrus and some temple records). If Horus (Mars) appeared at 30-year intervals for 300 years, then 10 visits would have been made between 3147 BC and 2850 BC (2770 BC if the 80 years of "negotiations" after 3147 BC are included).

A number of things will strike you in looking at the *King List*. First, the length of reigns at the start of the lists (Kish and early Uruk) are again extravagant -- reigns of 300 to 1500 "years" -- but mixed in are somewhat shorter reigns. Immediately after Gilgamesh (fifth king of Uruk) the reign lengths become reasonable. The later Second Dynasty at Kish again shows a few extravagant numbers.

Second, there is a lot of overlap, even though the lists in all instances read (to us) as if the dynasties at various cities follow each other chronologically. For the later dynasties, archaeological dating has both shown the existence of such overlap and sorted out much of it. An overlap is also true for the listings of the first two cities, Kish and Uruk. A summary follows below.

Kings After the Flood by Cities from the King List			
city	kings	reign yrs	date and notes
-----	-----	-----	-----
Kish	23	24,510	3147 BC - starting date
Uruk	12	2,310	ends ca 2700 BC (long reigns)
Urim	4	177	Gilgamesh at 2700 BC (some long reigns)
Awan	3	356	
Kish 2	8	3,195	includes some long reigns
Hamazi	1	360	
Uruk 2	3	187	
Urim 2	3	582	
Adab	1	90	
Mari	6	136	
Akak	6	99	
Kish 3,4	8	212	2365 BC (?) (one 100-yr reign)
Uruk 3	1	25	2335 BC Sargon of Akkad defeats Kish
Akkad	12	197	2193 Fall of Akkad
(dynasties after the fall of Akkad...)			
Uruk 4	5	30	
Gutium	21	95	
Uruk 5	1	27	
Urim 3	5	108	
Isin	14 kings	203 yrs	2004 BC end date
(The last kings of Isin are under Babylonian control)			

The complete list of the "kings after the flood" has held up archaeologically, but the early portion is often thought to be "legendary" by archaeologists, like the list of "kings before the flood." But even for Kish, the 13th, 14th, and 23rd kings have been dated archaeologically. After Gilgamesh of Uruk it is easy to arrive at a second date of certainty, for example, the conquest after 2335 BC of all of Sumer by Sargon of Akkad. All five generations of the Akkadian kings are archaeologically dated with confidence.

The City of Kish

It is difficult to conceive that a collation of records from a dozen locations, dating back over a thousand years, was first attempted as late as 2000 BC. My sense is that the first attempt to extend the records from before 3147 BC was made in Uruk after 2700 BC -- after the "reign" of Gilgamesh. This early attempt to tabulate the historical records of the cities of Kish and Uruk had to account for 400 years.

The record of the kings of the first city, Kish in Northern Mesopotamia, is the longest record of reigns of any of the cities, both in the raw information as presented to us, and in terms of "adjusted years" -- which I will detail below. Because of the extremely long reigns, the record for Kish becomes suspect of being a record of celestial beings -- in effect, the ten visits of Mars after 3147 BC -- conformed to actual kings who may have reigned at Kish, or the acceptance of a celestial God as the ruler.

Below is a verbatim rendition of the *King List* for the city of Kish. (See the endnote for mss. sources.) I will follow with more detail and some notes.

Kings of Kish

"After the flood had swept over, and the kingship had descended from heaven, the kingship was in Kish."

- 1 In Kish, Jucur became king; he ruled for 1200 years.
- 2 Kullassina-bel ruled for 960 (ms. P2+L2 has instead: 900) years.
- 3 Nanjiclicma ruled for (ms. P2+L2 has:) 670 (?) years.
- 4 En-tarah-ana ruled for (ms. P2+L2 has:) 420 years, 3 months, and 3 1/2 days.
- 5 Babum ruled for (ms. P2+L2 has:) 300 years.
- 6 Puannum ruled for 840 (ms. P2+L2 has instead: 240) years.
- 7 Kalibum ruled for 960 (ms. P2+L2 has instead: 900) years.
- 8 Kalumum ruled for 840 (mss. P3+BT14, Su1 have instead: 900) years.
- 9 Zuqaqip ruled for 900 (ms. Su1 has instead: 600) years. (In mss. P2+L2, P3+BT14, P5, the 10th and 11th rulers of the dynasty precede the 8th and 9th.)
- 10 Atab (mss. P2+L2, P3+BT14, P5 have instead: Aba) ruled for 600 years.
- 11 Macda, the son of Atab, ruled for 840 (ms. Su1 has instead: 720) years.
- 12 Arwium, the son of Macda, ruled for 720 years.
- 13 Etana, the shepherd, who ascended to heaven and consolidated all the foreign countries, became king; he ruled for 1500 (ms. P2+L2 has instead: 635) years.
- 14 Balih, the son of Etana, ruled for 400 (mss. P2+L2, Su1 have instead: 410) years.
- 15 En-me-nuna ruled for 660 (ms. P2+L2 has instead: 621) years.
- 16 Melem-Kish, the son of En-me-nuna, ruled for 900 years. (ms. P3+BT14 adds:) 1560 are the years of the dynasty of En-me-nuna.
- 17 Barsal-nuna, the son of En-me-nuna, (mss. P5, P3+BT14 have instead: Barsal-nuna) ruled for 1200 years.
- 18 Zamug, the son of Barsal-nuna, ruled for 140 years.
- 19 Tizqar, the son of Zamug, ruled for 305 years. (ms. P3+BT14 adds:) 1620 + X
- 20 Ilku ruled for 900 years.
- 21 Iltasadum ruled for 1200 years.
- 22 En-men-barage-si, who made the land of Elam submit, became king; he ruled for 900 years.
- 23 Aga, the son of En-men-barage-si, ruled for 625 years. (ms. P3+BT14 adds:) 1525 are the years of the dynasty of En-men-barage-si.

"23 kings; they ruled for 24510 years, 3 months, and 3 1/2 days."

"Then Kish was defeated and the kingship was taken to E-ana."

[\[note 6\]](#)

E-ana, where kingship is taken at the end of this dynasty, is the temple of An at (or near) Uruk. As you can read above, the 23 kings rule for 24,510 years, 3 months, and 3 1/2 days. This total would have been inscribed, in typical Sumerian accounting practice, on the back side of the tablet.

But the reign lengths *do not* add up to 24,510 years. Something is wrong with the list, even

though this version is a standard and a reliable translation. All the variant versions claim 24,510 as a grand total. As shown above, the total comes to 17,980 years. Some 6,500 years would have to be added to make up the difference, and this cannot be done by any stretch of the imagination. I will propose a number of causes for the discrepancy, and a solution.

It has been suggested by others that the reigns for Kish do not add up because there are some numbers missing and there were copying errors. In fact, many of the tablets have some damage and also show divergent reign lengths. The reason the grand total remains the same is from the practice used with the accounting tablets since long before 2000 BC which show tallies and subtotals on one face and the grand total on the reverse. Thus the scribes who copied one tablet to another did so without ever checking if the numbers added up. It seems archaeologists also never checked.

All the lists of "kings after the flood" differ from the list of "kings before the flood." The "saros" is never used again, nor the literary style used to describe each city. But the lists for the first dynasties of Kish and Uruk also differ from any of the following lists, not only because of the long reign lengths, but also because these two lists include short descriptive phrases for a number of kings, something not found anywhere else, with one exception (Kish, Dynasty 3) and the obvious editorial comments after the fall of the Akkadian empire, which reads, *"after the Gutium Hordes seized kingship, everyone was his own king for 3 years."* The descriptive phrases of the first two lists read very similar to those found among the genealogies of the book of Genesis, and include the following:

- Kish: *"Etana, the shepherd who ascended to Heaven and made firm all the lands."* (the ascension was "on the wings of an eagle," reminiscent of winged Mercury, which show up at the same time as Mars)
- Kish: *"Enmebaragesi, the king who smote the Land of Elam."*
- Uruk: *"Meskiaggasher, the son of the Sun God, Utu (Shamash), ruled as both lord and king for 324 years during which time he entered the sea and climbed the mountains;"*
- Uruk: *"Enmerkar, the son of Meskiaggasher, the king of Uruk who had founded Uruk."*
- Uruk: *"Dumuzi, the fisherman who came from the city of Kuara."*
- and the note for Gilgamesh: *"Gilgamesh, whose father was a spirit."*

This is a mix of attributes which can be assigned to outstanding human kings and feats only to be accomplished by a God. This makes it look as if attributes of the visiting Mars were assigned to various actual kings. [\[note 7\]](#)

The note about Meskiaggasher (2740 BC at Uruk), who *"entered the sea and climbed the mountains,"* is interesting. This could be taken (as archaeologists have suggested), as the expansion of the trade of Sumer by Uruk at a location better served for contact via the Persian Gulf than northern Kish was -- ascending the Zagros mountains to reach the Iranian plateau, and entering the Gulf to reach Pakistan and the Arabian peninsula, as well as East Africa (all of which was actually done). But it can also be understood as Horus climbing his mountain, followed by a disappearance into the sea of the south skies, the Absu.

Additionally, the various symbols used for large numeric quantities had not stabilized during the early Sumerian period, despite the fact that the tallies of tokens had been in use for nearly 5000 years in Northern Mesopotamia. It is possible that the scribes of Uruk who first inspected the stolen temple records of Kish just misread the data. Once this happened, the erroneous data just carried forward, for if nothing else, the records we have show that very little editing was done. A case in point is the reign of En-tarah-ana, the 4th king of Kish, who "ruled for 420 years, 3 months, and 3 1/2 days." Despite the fact that the 3 months and 3 1/2 days could have been dropped long ago, it was carried forward for a thousand years, and always included in the grand total. There were no months at this time, in that there was no Moon as yet. [\[note 8\]](#)

Lastly, our Indo-European concepts of sequential time will have us completely misread the intentions of the scribes of early Sumer by making assumptions about relationships from the texts which were never intended. The obvious example is that the lists are assumed to be consecutive by us. This has proven to be completely false; the scribes had no such intention. When a list reads, "and then kingship transferred to so-and-so city," it could happen any time in the chronology of the so-and-so city. For example, at the end of the First Dynasty of Kish, kingship is transferred to Uruk, but it is after the time of the fifth king of Uruk, not at the time of the first king of Uruk. The later scribes of Sumer were aware of these discontinuities also, but the practice of assigning kingship to various cities on a rotating basis, which had

started with Kish and Uruk, was continued as a "method" into the future.

Even within the list for any city it would be *our expectation* to find the reigns closely consecutive, that is, without gaps of time where there is no king, and without periods where two kings might rule simultaneously. But this might not have been the case, and ought to be allowed for as a possibility. It has also been noted by others that some "reigns" might represent the length of life of a king rather than the years spent on the throne. These two "solutions" have already been adopted by archaeologists.

But none of the caveats and conditions listed above properly explains the discrepant long reigns of Kish and Uruk, or the mismatched grand total for Kish. A misreading of ciphers has to be kept in mind, though, and a complete misreading of the first records of Kish by the scribes of Uruk comes closest to a rescue of the situation. This also applies to the early record of Uruk.

Finding and applying a corrective factor to the discrepant reign lengths which makes all of the lists coherent is perhaps easier than finding the cause of the misreadings. What I propose is that the early records either overstate or were misread by a factor of 60. [\[note 9\]](#)

Dividing all the listed reigns by 60 yields reasonable year lengths, reasonable, that is, for celestial phenomena. It brings the whole series to the time of Gilgamesh, although we still end up with spans of 15 to 20 years, which are generally too long as the reign lengths for normal human kings. Thus I suspect that the list of kings for Kish concerns itself with celestial beings, perhaps along with real people. More on this below.

In the listing below, I have reduced all the reign lengths of the kings of Kish from the extravagant periods of "900 years" or more to something more realistic by dividing all the entries by 60. (The first kings of Uruk are listed further below.)

The summary below uses a starting date of 3067 BC. This is 80 years after the end of the "Era of the Gods" in 3147 BC, and represents the period of time that it took the Gods of Egypt to negotiate who among them would rule Egypt. The 80 years is mentioned in very late Egyptian sources. The rulership of Egypt was (after 80 years) assigned to Horus/Mars. I will suggest that the first kings of Mesopotamia and the first kings of Egypt were celestial beings, not humans.

The orbit of Mars is too large for Mars to have been released from Saturn at the same location from the Sun that Earth and Venus were. We could assume that Mars remained entwined with Saturn until the asteroid belt was reached, some 50 to 60 million miles (80 to 100 million km) beyond Earth's orbit. Certain descriptive details in the records of Egypt, which are associated with the earliest records of Horus, would demand as much. We could assume that Mars did not come close to Earth until 3067 BC -- 80 years after 3147 BC.

Kings of Kish After the Flood

tallies in '60s' adds up correctly
notes () are listed below

Name	Length	/60	end year	notes
-----	-----	---	-----	-----
			3067	starting date
1 Jucur	1,200	20	3047	
2 Kullassina-bel	960	16	3031	
3 Nanjiclicma	670	11.1	3020	rounded

21 Iltasadum	1,200	20	2793	
22 En-men-barage-si	900	15	2778	(3) ca 2750 BC
23 Aga	625	10.4	2768	rounded (4)
Total: 23 kings	17,980	299.6	total of reign entries	
23 kings;	24,510	408.5	original document total	
Notes:				
Note (1): coincidence of Kish 14 and Uruk 1.				
Note (2): coincidence of Kish 17 and Uruk 3 (?)				
Note (3): coincident reign with Uruk's Lugabanda.				
Note (4): meets Gilgamesh, ca 2700 (literary source)				

The difference between a starting date of 3147 BC and 3067 BC is justified as follows:

Tom van Flandern suggests that a satellite which just follows along with another planet (without the need to orbit the parent planet), will quit this behavior when the parent planet nears another large mass, reducing the parent's "gravitational sphere of influence." I'm suggesting that the asteroid belt represented such an influence. Both Mars and Mercury were released as Saturn entered the asteroid belt.

Mars (Horus) was involved in the 80 years of "negotiation" among the Gods before showing up (in Egypt) to claim rulership of the land. (The story dates from the 12th dynasty circa 1500 BC and is recorded circa 700 BC in the *Chester Beatty Papyrus*, now at Dublin.) In 3067 BC Mars must have gone into an elliptical orbit around the Sun with an aphelion near (or within) the asteroid belt, and a perihelion inside the orbit of Earth. Additionally it seems likely that Mars passed (infrequently) very close Earth. We do not know this exactly, but it can be surmised from the list of the kings of Kish, the first two pharaohic dynasties of Egypt, and even the current orbit of Mars, which still closes in on Earth every 30 years.

It seems quite possible that the close approaches between Mars and Earth would only last for short periods of time -- days -- over a period of 300 years (so claim the Egyptians) and at 30-year intervals. The orbit of Mars might change with each near contact with Earth, although likely to be corrected with the next close pass. Earth, with 10 times the mass of Mars, would not be significantly affected.

It is possible that the Sed festival of the Egyptian pharaohs was established on the basis of these infrequent incidents, when Mars would have formed a mountain form with the ionosphere of Earth -- what would have looked like a solid pyramidal form -- before the return and overpassings of Mars began to be measured differently.

The advantage of starting in 3067 BC rather than 3147 BC is that the 300-year record of the kings of Kish now ends correctly at the time of Gilgamesh, who is dated at about 2700 or 2750 BC. Aga, the last king of Kish, is confronted by Gilgamesh, and is captured by Gilgamesh. The Sumerian legend *Gilgamesh and Aga* recounts this, although the information of the capture (and release) of Aga seems to have been appended as an afterthought. The main theme of *Gilgamesh and Aga* is how Gilgamesh stood up against the demands of the city of Kish, an event which forever changed the politics of Sumer. How important the primacy of Kish had been is shown by the titles taken by many later kings of other Sumerian and Akkadian cities, as "King of Kish and so-and-so."

Ending a 300-year period at about 2750 BC makes a better fit also to the end of the Egyptian list of Horus pharaohs (the first two dynasties), and the start of pyramid building worldwide. Additionally, the 300-year period equals the life span of Horus, listed as 300 years in the Turin Papyrus, and other records. Other literary sources suggest that the Sed festival was celebrated at 30-year intervals (there is also at least one mention of 20 years). I think that the Sed festival might have celebrated the visitations of Horus, but it is also possible that the Sed festival dates from the time of the southern ball plasmoid and the overhead lines of electrons in the sky, and represents a symbolic survey of the land.

But what is the meaning of the grand total of 24,510 years (408.5 real years) for the kings of Kish, when the total of the reigns add up to only 17,980 years (299.6 real years)? I think the "24,510 years" represents the interval between the date when the "flood swept over," which is the opening statement of the tally, and the date of the end of the listing of the kings of Kish. It thus represents a span of 408 years ending in about 2750 BC, but only during the last 300 years were there any kings assigned to Kish, ending circa 2768 BC.

The scribes were correct; it was only we who had understood the "24,510 years" as the mathematical total of the individual reign lengths. The last line of the tablets, which reads "23 kings ruled for 24,510 years" should really read "23 kings ruled *during* 24,510 years" to conform to *our* notions of the passage of time.

There is one more problem to be resolved. If at this point we were to look for celestial kings in the list of kings of Kish -- visits by Mars/Horus -- the first suggestion would be to assign them to the anomalously long reigns, of which five are on the order of 1200 and 1560 "years" in the original texts (equal to 20 "adjusted" years), and another 15 instances at 10 to 16 "adjusted" years. There are altogether some 20 of these "long" reigns. This differs from what has been assumed from later Egyptian sources, which claims ten visitations at 30-year intervals (although there are also some 17 to 19 pharaohs in the first two Egyptian dynasties between 3050 BC and 2700 BC).

In fact, what I think we are looking at is the records of the close approaches of *two* planets -- Mars and Mercury. It is certain that Mercury was seen in the skies from very early times (but not in its present position close to the Sun) for the Turin Papyrus lists Thoth (Mercury) with a life span of 3126 years, the longest life span by far of any of the Gods. What we are looking at, therefore, is a set of two repeating appearances, Mars on a 30-year cycle and Mercury on an equal or similar cycle. [\[note 10\]](#)

That is one possibility. Another is the fact that Mars would cross over the Earth on its way toward perihelion behind the Sun, and would return on a similar schedule, that is, it would cross over again in the opposite direction at a later date in moving from near the Sun to the far reaches of space. What suggests this process is the much later movements of Mars between 806 BC and 687 BC, which was on a 14- or 15-year interval, alternating between approaching the Sun and movement away from the Sun. (Mars would, of course, orbit the Sun on an approximate two-year cycle, but only at 15-year or 30-year intervals would the Mars orbit coincide with the location of Earth on its path.)

This particular solution also solves the problem that there is no mythology of Mercury at this early time.

In either case we would need to recognize repeating cycles by combining the kings into groups of two (or more) -- one accounting for a crossing of Mars, followed some years later by a crossing of Mercury (or the return crossing by Mars). If this is done, the list above reduces to a series of 10 time spans, as follows:

36, 23+, 30, 29, 24, 37, 33-, 27+, 35, 24+

But this can also be arranged as follows:

36, 37, 30, 25, 26, 32-, 26, 27, 35, 24+

Obviously other combinations can be found. The above data is shown in the table below, along with another group of 11. What this grouping by two's does is to swallow the visits of one of the planets or the reign of one of the assigned kings.

Table of the First Dynasty of Kish					
Name	Length	/60	possible groupings		
-----	-----	---	(10)	(10)	(11)
1 Jucur	1,200	20			20
2 Kullassina-bel	960	16	36	36	
3 Nanjiclicma	670	11.1			27
4 En-tarah-ana	420	7			
5 Babum	300	5	23.1		
6 Puannum	840	14		37	26
7 Kalibum	960	16	30		
8 Kalumum	840	14		30	30
9 Zuqaqip	900	15	29		
10 Atab	600	10		25	25
11 Macda	840	14	24		
12 Arwium	720	12		26	26

13	Etana	1,500	25	37		
14	Balih	400	6.7		31.7	31.7
15	En-me-nuna	660	11			
16	Melem-Kic	900	15	32.7	26	26
17	Barsal-nuna	1,200	20			
18	Zamug	140	2.3			
19	Tizqar	305	5.1	27.4	27.4	27.4
20	Ilku	900	15			
21	Iltasadum	1,200	20	35	35	35
22	En-men-barage-si	900	15			
23	Aga	625	10.4	25.4	25.4	25.4
Total: 23 kings		17,980	299.6	(10)	(10)	(11)

For an alternate list (the alternative dates shown in the verbose transcription above), I get a series of 10 time spans as follows: [\[note 11\]](#)

35, 27+, 30, 32, 29+, 25+, 22+, 27, 35, 25+

As shown above, there are not 10 visits at 30-year intervals as guessed from Egyptian sources, but 10 visits at various spans of time between 35 and 25 years apart. They average to 29.8 years, or to 30.4 if the last value of 25.4 is removed.

The orbit of Mars might be constantly adjusted by the periodic near contacts with Earth, although the two intervals making up the combined span of time of approximately 30 years is very regular throughout much of the list. We are not looking at synodic periods which might have been noticed. Synodic periods are small in comparison to the 34- to 20-year intervals. We are looking at the close approaches or overpasses of two planets. [\[note 12\]](#)

I should again point out that the 30- or 20-year intervals do not represent the orbital period of either Mars or Mercury. These remain at around two years for Mars and probably the same for Mercury. Only at the long intervals listed above would they cross the Earth's orbit near the location of Earth.

The planet God Saturn had ruled humanity for a thousand years. Then after 3147 BC came a period of uncertainty. But after 3067 BC Mars showed up again and was welcomed as the God and ruler. The repeated returns constituted the "kings" of Kish. The pharaohs of the first and second dynasty of Egypt form a parallel record.

It is quite possible that we should not be looking for 30-year intervals, but for 32-year intervals. As I mentioned above, all the reigns of the "kings before the flood" are multiples of 32. In Western Europe there are a number of early megalithic grave sites with 32 or 34 distinct markers. The numbers 32 and 34 appear all too frequently as markers among the megalithic grave barrows to be mere coincidence.

The "34" likely represents a counting system which counted the intervals which included the endpoints of a time span which we would identify as an interval, and is seen in use elsewhere in antiquity, as late as Imperial Roman times. The Roman day-of-the-month count was numbered in such an absurd system. This is not an uncommon antique counting system. [\[note 13\]](#)

The only other countable elements of the megalithic chambers are the serpentine twinings used as decorations. But these make no sense. They appear in groups of 4, 6, 7, 8, 12, 13, 29, and 30. Some people would equate the groups of 29 and 30 with the orbit of the Moon. But there was no Moon.

There are 34 standing stones at a number of barrow locations in Ireland. Perhaps these people were counting 32-year intervals between times when the God would come to gather the dead, but counting the first and the last year twice for every interval. I would suggest that the various sets of 34 stones represent a span of 32 years, where the very beginning and the completion of an interval are also counted. Normally inclusive counting adds up to 33, not 34, if the markers are counted. However, the interstitial spaces between 34 markers yields the number 33, which is an "inclusive" count of 32. [\[note 14\]](#)

The later New Grange barrow does better. Of the 96 curb stones at the base, 32 are decorated -- incised with whorls -- the last, a very large decorated stone, lies in front of the entrance. New Grange was certainly built after 3147 BC, and thus may have been designed around possible 32-year inclusive intervals between visits by Mars after 3067 BC.

If Mars actually showed up near Earth at regular 32-year inclusive intervals, then there might have been a need for the early chroniclers of the *King List* to make sure that the visits of Mars prior to the flood were also recorded in 32-year intervals. That, to me, seems the only resolution of the multiples of 32 years used for reign lengths of the "kings before the flood." That also reduces the confidence that the reign lengths are exact tallies of the time intervals.

Mars/Horus fails to show up after circa 2750 BC. Perhaps some undetermined celestial event terminated the visits of Mars, although it is more likely that the second nodal points of the elliptical orbits of Earth and Mars had revolved away from each other.

The City of Uruk

The midpoint of the career of Gilgamesh is estimated at 2700 BC, Carbon-14 dated from the reconstruction of the walls of Uruk, attributed to him in legend. Following Gilgamesh the reign lengths become reasonable, and it looks like actual solar years were used. In the tabulation below I have used actual years (as reported in the record) from Gilgamesh on.

Table of the First Dynasty of Uruk					
	Name	Length	/60	end year	notes archaeological
1	Mec-ki-aj-gacir	324	5.4		(1) 2740 BC ?
2	Enmerkar	420	7		(2) 2750 BC ?
3	Lugalbanda	1,200	20		(3)
4	Dumuzid	100	1.6		(4)
5	Gilgamesh	126	126*	2650	(5) ca 2700 BC
6	Ur-lungal	30	30*	2620	
7	Udul-kalama	15	15*	2605	
8	La-ba'cum	9	9*	2596	
9	En-nun-tarah-ana	8	8*	2588	
10	Mec-he (the smith)	36	36*	2552	

11 Melem-anna	6	6*	2546	
12 Lugal-kitun	36	36*	2510	ca 2550 BC
		*	-- actual years used	
::: totals (Uruk) 2,310 300 years				
Notes:				
Note (1): coincidence of Kish 14 and Uruk 1, dated 2720 or 2740 BC.				
Note (2): literary ~2750.				
Note (3): coincidence of Kish 17 and Uruk 3 (?), father of Gilgamesh.				
Note (4): Dumuzid captures second to last king of Kish, 22.				
Note (5): Gilgamesh (in one of the Gilgamesh sagas) meets the last king of Kish, Aga.				

The end-years listed above are based on assuming the year 2700 BC represents the midpoint of the career of Gilgamesh. This has been Carbon-14 dated. Allowing 50 years before and after 2700 BC, Gilgamesh would have lived between 2750 and 2650 BC. The end-year for Aga of the city of Kish, 2768 BC, falls at the beginning of the interval which we can assign to Gilgamesh.

I have kept Gilgamesh's reign at 126 years even though this is not at all justified. Gilgamesh is probably the planet Mars. Dividing by 60 reduces his reign to 2 years. The fact is, I suspect that Gilgamesh is both Mars and a human.

From internal considerations, it would seem that the initial *King List* was probably first compiled after the time of Gilgamesh. A predecessor (Meskiaggasher, first king of Uruk) was listed as "the first to write on tablets" -- probably true for Southern Mesopotamia. It is to Meskiaggasher also that an expansion of trade was attributed. After Gilgamesh there is a sudden change in listing the reign lengths. Gilgamesh, located at the very end of the series of visits by Mars, becomes the Hercules of Sumer in the epics which follow.

From the last king of the first dynasty of Uruk, archaeologically dated to about 2550 BC (and as 2547 to 2510 BC in the listing above), there is a clear archaeological path of dates leading to the Akkadian empire of 2335 BC, and onward to dates for the rule of Isin in 2207 BC.

Parallel Histories

The purpose of the following section is to list the parallel mythologies (histories) of different people -- as a supplement to the analysis of the *King List* above. The purpose thus is to highlight the following:

- A record of eight lowerings of Mars before 3147 BC, that is, before the end of the "Era of the Gods," recognized as kings or godly rulers.
- A terminal date for the "Era of the Gods" when the polar configuration came apart. Details would include mention of the massive world flood of 3147 BC.
- A continuation of the chronology from this point in a record of the ten overflights of Mars after about 3067 BC and ending by about 2700 BC, and a transition at that time to a more solidly founded archaeological and chronological record.

Lastly, and although not forthcoming from all sources, a record of the apparition which stood above the north horizon for perhaps a thousand years. This would involve changes in how this looked, going from a shrouded sphere to a fireball, the stream of plasma in arc mode, followed by a continued plasma stream in glow mode. Details would include Venus connected to Saturn with a swirl of plasma.

Maya Parallels

Although the Maya disappear archaeologically before about 1500 BC, as do the Olmecs by 2000 BC, parallels are recorded in the books of the *Chilam Balam* of the 16th century AD. These were apparently copied from bark book codexes which are now lost to us. These records clearly date back to the end of the "Era of the Gods" and earlier. They were recopied to a European script by the Maya in the 16th century AD. The oldest historical records are found in Book 10 (and Book 11) of the Maya *Chilam Balam*.

The reference to the eight "kings before the flood" is the description of the ascension of Nine-Lives (Bolon Dzacab). He is known as Nine-Lives, I would suspect, because he ascends nine times and was seen close to Saturn nine times. Mesoamerican languages emphasize the completion of actions rather than the start. (The action was to leave behind a mountain of maize mash.) Similarly, Nine-Lives is only mentioned once since repetitions of the activity are not needed in a book of prophecies. Nine-Lives is known to be Mars. He is called "this first Bolon Dzacab," very similar to Egyptian naming of the early Horus as "Horus of the Gods." [\[note 15\]](#)

During the following period of Katun 9-Ahau (3087 to 3067 BC), "Ten-Sky" first appears, which are the close calls of Mars initiated after 3067 BC. Again, the repetitions are not noted. The name "Ten-Sky" is sufficient to indicate this. The same is done later for two series of repeating electric field interactions by Venus. Because only the Katun name is given, we do not know the actual date of the first appearance, only a 20-year range, but as guessed at above. Since all dates in the *Chilam Balam* books, except one (which was altered in antiquity), can be brought into concordance with estimated dates from Eastern Mediterranean sources, we can have considerable confidence in guessing the larger 400-year "Baktun" period, and the equivalent Gregorian dates.

Bible Parallels

The editors of the Old Testament recopied old books, collated manuscripts, and reviewed the *King List* some 2400 years ago. As the oldest extant historical document, the *King List* could not be neglected, although as likely many Bible sources were Egyptian. The editors were also 1500 years closer to the Sumerian sources of 2000 BC than we are today, and not only took the information seriously, but most likely read the Sumerian texts correctly, for there is close agreement on the time spans between the Bible and the *King List*, -- not the "unmodified"

long reign spans, but as modified by me above.

There have been attempts by Bible scholars to justify the time spans in years of the Sumerian "kings before the flood" with the Bible account of the time span from creation to the flood of Noah, and especially to somehow account for the long lives of the patriarchs. In both texts eight kings or patriarchs are listed -- nine patriarchs if Adam is included.

There is a relationship between the *King List* and the Bible, but it is hardly as simple as assuming that the Sumerian account just multiplied the account of the book of Genesis by some large number, as some have suggested. [\[note 16\]](#)

Note that according to the Bible Adam lived 930 years. We can assume that Saturn was understood as representing Adam, who "died" in 3147 BC. Subtracting Adam's life span from 3147 BC, brings us to 4077 BC -- close to my original estimate of 4100 BC as the date when Saturn went nova, and lit up like a sun -- the creation. Close, also, to Bishop Ussher's estimate of 4004 BC as the start of creation.

There can also be little doubt that the Bible mistook the flood of Noah, 2349 BC, for the world flood of 3147 BC. Adding the span of 1680 derived from the Bible as the number of years between creation and "the flood" brings us to 2397 BC. The calculation is **3147 + 930 - 1680 = 2397 BC** -- close enough to 2349 BC (my date). Ussher, using births and life spans from the Bible, calculates 1656 years. Josephus knew the span between creation and the flood as 1656 years, and might have subtracted 1656 from 3147 BC (my date for creation) to arrive at 1491 BC (as the "flood of Noah") but without identifying these years in our BC/AD calendar.

In fact, the flood of 3147 BC seems to have been neglected entirely. If we count Adam as representing Saturn, and remove Enoch as having far too short of a life, then there are 8 names left over, including Noah. And thus here, woven into this chronology, are the eight lowerings of Mars, who came to represent all the "patriarchs before the flood." [\[note 17\]](#)

The time from 3147 BC to Gilgamesh can similarly be compared to the narrative of the Bible. The period from the biblical flood (2349 BC) to the midpoint of Abraham's life is nearly equal to the time between the Mesopotamian flood of 3147 BC and the midpoint of Gilgamesh's reign (approximately 408 years). Both Gilgamesh and Abraham were heroes to their people, and "mythologically" located at the midpoints of two analogical world histories. Both may represent the last apparition of Mars and embody all the previous appearances, as Hercules does for the Greeks at a later date. I am here using Ussher's date of 2348 BC for the end of the Bible flood and 1921 BC for Abraham's arrival in Canaan as a midpoint (thus 427 years). That means, again, that the list for the kings of Kish was read correctly in 600 BC. [\[note 18\]](#)

Additionally, just as the list of the kings of Kish list 10 kings (although in groups of two) between the flood of 3147 and the time of Gilgamesh, and Egypt claims ten visits of Horus,

so the Bible lists 10 patriarchs between the "flood of 2349 BC" and Abraham. Abraham is the 10th generation born after Noah (I am counting Shem, son of Noah, actually born before the flood). All except the first and last of these 10 generations were sired when their father was 29, 30, 32, or 35 years old. After Abraham, as with Gilgamesh, the life spans become normal.

I do think that the Bible may have used the *King List* as a source. But what we are seeing is a record in parallel to the Sumerian sources, or Egyptian sources (since by tradition Moses was the original author of Genesis).

What I think we are seeing, as I have expressed earlier, are complete fictions, based on slim recollections, other peoples' stories, and a need for narrative continuity. Abraham, if equated to Jupiter, would have a first appearance as a giant figure in the sky two and a half days after the fall of the Absu (on the calendar date of September 6) in 2349 BC. If he then lives until 2150 BC (a most likely date for his demise) he would have lived 199 years. The year 2150 BC is what I had earlier selected as the year that Jupiter blazed in flames and disappeared from view (died) to be seen afterwards only as a star.

The Bible, however, claims Abraham lived 175 years, and also places his whole life at a completely different time period. The difference between 199 years and 175 years is considerable. We should accept either the year of Abraham's first appearance (2349 BC) or the year of his end (2150 BC) as certain. It is possible that 2150 BC is not as hard and fast as I may have suggested. However, the Maya *Chilam Balam* comes to the same conclusion for the burning of Jupiter, placing it in a Katun which includes 2150 BC. The demise of Jupiter happened in a Katun 8-Ahau (2.10.0.0.0) which is a 20-year period nominally ending in 2128 BC, but should be corrected to 2167 - 2147 BC. This includes 2150 BC.

The other correction by 25 years would be to suggest a "birth" for Abraham in 2325 BC, some 25 years after the "flood of Noah." The only celestial event that can be tagged to this date, or some date close to it, would be the regularization of the Moon. I have previously suggested that I cannot with any certainty place the year when the Moon started to orbit Earth, except to say that it probably was shortly after 2349 BC, after the Earth had moved to a larger orbit. A best suggestion for a date comes from the Chinese Annals of Shu, which assigns the birth of Shun (the Moon) to 2318 BC. The dates derived from the Annals of Shu may not be entirely correct, but the date is closer to 2325 BC.

So, now what? I would suggest that the "birth of the Moon" was mistaken or misread for the birth of Abraham. There is some elegance to this solution: this disconnects Abraham from the "flood" and it disconnects him from being a God who appears fully formed in the sky suddenly. It is obvious that the 6th century BC Bible editors confused the flood of 2349 BC with the flood of 3147 BC (as many people did), and had to place the birth of Abraham (additionally) 400 years later to have his life follow the offspring of Noah. Typical of the Bible, as with many other sources of antiquity, is that spans of time are often accurate, even when there seldom are any starting or terminal dates. So the 175 years for the lifespan of Abraham remains as correct, even if the dates of his birth and death are altogether uncertain.

Egyptian Parallels

Egyptian parallels can be found from three sources for the kings of the first and second dynasties: (1) the Palermo stone list of kings (about 2550 BC), (2) the Turin Papyrus list of kings (circa 1200 BC, or more likely 950 BC), and (3) the written records of kings left by Manetho (about 300 to 200 BC). These last, although spanning 2200 years, are congruent for all practical purposes, and mostly validate each other. I will discuss the predynastic archaeological record separately further below.

The pharaohs from the First through the Second Dynasty use "Horus names." There is one exception in the middle of this list, a pharaoh who takes a "Seth name." After this one use, no pharaoh ever takes a Seth name again (excepting once more in the 19th Dynasty after 1300 BC). The second dynasty ends in 2705. It is the first and second dynasty which ought to be compared to the list of "kings after the flood" and the Bible patriarchs.

The dynasty groupings may have been selected by Manetho, perhaps arbitrarily, although these could represent family groups, or represent blocks of a unified political or religious climate. It has also been suggested that some dynasties may have been grouped by the location (city) which held political power for a length of time. Thus the separation of the early kings in Egypt into the first, second, and third dynasty may not mean anything.

The break between Dynasty 1 and Dynasty 2 is equivalent to the division at Kish between kings with "animal names" and the group of 10 kings starting with Etana. But Dynasty 1 ends in 2857 BC, and Etana is placed (by me) in 2913 to 2888 BC. I have also noted that the end of the first dynasty coincides with the disappearance of Jupiter into the asteroid belt in circa 2860 BC (as calculated by me). [\[note 19\]](#)

The second dynasty ends in 2705 -- coinciding with what I have assumed to be the last apparition of Horus. The use of pyramids as grave markers starts with the following third dynasty of Egypt after 2650 BC -- 50 or 100 years after Mars/Horus is no longer seen in the skies close to Earth. The first ziggurat (the E-ana at Uruk) appears in Mesopotamia at the same date. The construction of pyramids starts in the Andes at the same time (circa 2650 BC), and the effort at constructing a giant conical mountain happens in England around 2500 BC. Again, I have to invoke van der Sluijs's comment that the Gods (and their activities and symbols) are localized after they are no longer present in the skies. [\[note 20\]](#)

The graves of the Horus pharaohs at Abydos (Central to Upper Egypt) are apparently cenotaphs, with the alternate (real) burials at Saqqara (or, as currently understood, the reverse of this). Abydos is also the city of Osiris, and his "grave" had become a site of pilgrimages in late antiquity. If then the graves at Abydos start with the grave of Osiris, followed by a dozen graves of Horus, it might be suggested that the Egyptians *pro forma* provided graves for the deity which the pharaoh represented. The alternate (and accepted) explanation is that the cenotaphs were politically significant -- in representing separate graves as "King of Lower

Egypt" and as "King of Upper Egypt," although this is a modern political interpretation. There were no separate kings of Upper and Lower Egypt. It is all too obvious that we should seek explanations in ancient religious motivations, not in modern political philosophy.

There are, as there are in Mesopotamia, some 20 pharaohs, but possibly 17. The reign lengths for most are far too long as earthly kings, and the series also does not follow the obvious progression of a series of 30-year intervals. The reign lengths of the first and second dynasty pharaohs depend mostly on archaeological findings and archaeological dating, and are not as concrete as the Mesopotamian written record. The Turin papyrus gives dates which are much too long, and the Palermo stone is very incomplete.

Chinese Parallels

There are ten "Legendary Emperors of China" as listed by Joseph Campbell, but only eight in number from Taoist sources, a set of three nobles, followed by a set of five "Tis" (Tîs) -- a word clearly meaning "Gods" but usually translated as "Emperors." Considering that the dates assigned to these eight or ten "Legendary Emperors" falls after 3147 BC, at first glance it looks similar to the Mesopotamian list of the "kings after the flood."

Fu Shi, wrote Campbell, is equated with Adam. Even so, following him, Shen Nung, who must represent the egg in the sky, lived 17 generations (from some sources), thus about 820 years, not far from my estimate of 720 solar years. However, all the listed dates are in complete disorder. It is more likely that the three nobles represent the three ball plasmoids in the south, and the three periods in the remote past that these were seen.

Legendary Emperors of China				
Ruler	Reign Length	years	notes	
Period of the three nobles "San-huang"				
1 Fu Shi	115 years	2953-2838 BC	or 17 generations	
2 Shen Nung	120 years	2838-2718 BC		
3 Yen Ti	21 years	2718-2598 BC		
Period of the 5 emperors "Wû Ti"				
1 Huang Ti	100 years	2698-2598 BC	"Yellow Emperor"	
2 Shao Hao	84 years	2598-2514 BC	Kin-Tien	
3 Chuan Hsi	78 years	2514-2436 BC	Kao-Yang	
? Ti Kao	70 years	2436-2366 BC	(K'u? -- Gu)	
4 Yao	102 years	2357-2255 BC		
5 Shun	50 years	2255-2205 BC		
Yu		2205-2197 BC	Xia first king	

"Prior to the dynasty of Hsiâ [Xia], with the exception of the period of Yao and Shun, the accounts which we have of the history of China have been, and ought to be, pronounced "fabulous" and "legendary." The oldest documents that purport to be historical are the books in the Shu; about Yao and Shun, and even they do not profess to be contemporaneous with those personages."

-- James Legge, introduction to *The Sacred Books of the East, The Shu King* (volume 3) (1879).

Huang Ti, the "Yellow Emperor," has long been identified as Saturn. The lifetime of Huang Ti is only listed as 100 years, even though he brought all the gifts of civilization to China. Other information lists his reign as 300 years (Confucius).

"He consulted with his sages while deliberating on the "Bright Terrace;" ... he assembled the spirits on the holy mount T'ai-shan."

-- <http://www.world-destiny.org/>

The Taoist groupings reflect philosophical concerns. There are five Legendary Emperors to match the five elements. But later Taoist writings also define eight "immortals" as exemplary figures of the past. Legge notes that:

"In the fourth Book of the Li Kî is called Yüeh Ling, 'the Monthly Record of the Proceedings of Government.' In it certain sacrificial observances paid to the five Tîs are distributed through the four seasons. The Tîs are Fû-hsî, Shan-nang, Yü-hsiung or Hsien-yüan, Kin-thien, and Kâo-yang, who are styled the Greatly Resplendent, the Blazing, the Yellow, the Less Resplendent, and the Solely Correct."

This listing seems to be a description of manifestations of Saturn, before the end of the "Era of the Gods," and, the last, Jupiter after 3147 BC, as the titles clearly indicate. If the above list is in the correct order, the Gods can be assigned to a chronological series as follows (I have included the reign lengths as listed further above):

- Fû-hsî -- "the Greatly Resplendent" -- Saturn as a globe (the egg) standing above the North Pole after circa 9000 BC, and clearly seen since perhaps 5800 BC. 115 years, but elsewhere listed as "17 generations."
- Shan-nang -- "the Blazing" -- Saturn after going nova in 4077 BC. 120 years.
- Hsien-yüan -- "the Yellow" -- Saturn still in arc mode discharge, or reduced to glow mode level. This is Huang Ti in the list above. 100 years.
- Kin-thien -- "the Less Resplendent" -- Saturn in a late, less active mode, perhaps completely reduced to glow mode plasma discharge. 78 years.
- Kâo-yang -- "the Solely Correct" -- I suspect this to be Jupiter as the Midnight Sun after 3147 BC through perhaps 2300 BC. 70 years. However, see below.

The total time span of the first four Saturn manifestations is only 413 years. This certainly falls far short of my estimate based on the Sumerian King List. But it is close to the time span between 3147 BC and the last visit by Mars/Horus (the transfer of power from Kish to Uruk). The assigned dates (years) may thus have come from a much later period.

There is also a late tradition of five Tîs which includes two or three of the three nobles, two names from among the "legendary emperors" as listed above (plus one additional name?), and excludes Yao or Shun. James Legge additionally notes that:

"The earlier accounts open with a Phan-kû, in whose time 'heaven and earth were first separated.' To him succeeded the period of the San Hwang, or Three August Lines, consisting of twelve Celestial, eleven Terrestrial, and nine Human Sovereigns, who ruled together about 50,000 years. After them come a host of different Lines, till we arrive at the Wû Tî, or Five Emperors."

The date for when "heaven and earth were first separated" is likely the end of the manifestations of the southern ball plasmoids in 8347 BC or could be the end of the "Era of the Gods," 3147 BC, but it certainly is not followed by a 50,000-year period of rulers. It may also represent a failure of one of the periods of the southern ball plasmoids. Egyptian "mythological history" interestingly includes the same excessive time span for a large number of unnamed rulers, the "Followers of Horus." In both cases these may be asteroids on a path crossing Earth's orbit, what today would be called a meteor swarm. The 50,000-year period is likely the sum total of all their simultaneous appearances, or may represent the fact that these objects in the sky (which I will assume them to be) had appeared since ages immemorial.

The dates (in the table above) were arrived at in the 100-year period after the book burning of 213 BC, probably by Taoist scholars working from uncertain sources, and often by simply assigning reign lengths to lists of emperors of the various dynasties. The chronology which was determined at that time has the following time spans and dates for the dynasties preceding the Chin (quoting Legge):

- *Hsî [Xia] lasted for 439 years, from B.C. 2205 to 1767.*
- *Shang or Yin endured for 644 years, from B.C. 1766 to 1123.*
- *The Kâ [Chou] continued for 867 years, from B.C. 1122 to 256.*
- *founding of Khin [Chin] dynasty in B.C. 221.*

Legge, on the other hand, suggests a minimum of 500 years for each of the dynasties, based on Mencius (a follower of Confucius), as the Taoists writers might initially also have used. Either calculation places Yao in circa 2300 BC, or at the time of the "flood of Noah" of 2349 BC, and has Shun end his activities shortly before the worldwide climatic downturn of 2193 BC. Yao is Jupiter; Shun is the Moon. That much is certain.

The similarity to the list of the "kings after the flood" ends here. The complete time span of the three Dukes and five Emperors, from the accession of Fu Shi in 2953 BC (already one hundred years late) to the accession of Yü in 2205 BC, amounts to 748 years. This is much too long to represent the comings and goings of Mars/Horus between 3000 and 2700 BC. The celestial nature of these "Legendary Emperors" is assured, however, in the information supplied for them.

- *"Fu Xi is represented as a human being with the body of a snake." This is most likely the southern plasmoid and its electron beam extensions in the era after 10,900 BC.*
- *"San-huang is sometimes portrayed with the head of an ox." This recalls the celestial*

bull of Sumerian sources, and ought to be equated with Jupiter.

- "*Huang-di is credited with the creation of mankind; a dragon descended from heaven and carried him aloft.*"
- "*After the death of Yao, Shun seated himself on the throne. Ten suns appeared in the sky, threatening to scorch the earth to a cinder. The heavenly archer Shen Yi managed to shoot nine out of the sky with his magic bow.*" This will be recognized as the plasmoids delivered in 2349 BC by Venus.

The Tîs bestow the gifts of civilization to mankind -- the ordering of tribes, giving of family names, agriculture, irrigation, fishing nets, music, medicine, writing, pottery, silk worm breeding, and, amazingly, the creation of mankind itself. This is the same set of gifts received from the Gods in Mesopotamia during the "Era of the Gods."

What I think we are looking at is a recollection from the "Era of the Gods," not the celestial kings (or Gods) after 3147 BC. The period of the "Legendary Emperors" (and the three Dukes) is 748 years. My estimates from the Sumerian *King List* is that the "Era of the Gods" lasted 1072 years. I have no problem with the differences in these time spans, since it seems obvious that the Chinese records were displaced by a thousand years to mark the beginning of creation.

This involves not only a confusion of the descents of Mars during the "Era of the Gods" with the similar visits by Mars during the period after 3147 BC, but, as many people had done, a confusion of the flood of 3147 BC and the flood of 2349 BC. In effect the record, which originally ended in the flood of 3147 BC, was moved to an era also ending in a flood -- the "Noachian flood" of 2349 BC.

In the Chinese *Annals of Shu*, after 2349 BC, Yao sends his astronomers to the four borders of China to observe the stars and determine the calendar. But, as Chinese scholars have noted, Yao already knew the answers, and states them. He also proclaims that "a round year consists of three hundred, sixty, and six days" and that the year and the seasons are to be completed by the use of an "the intercalary month."

It is fairly certain that the *Shu* existed already in 700 BC. The chapter, however, which tells of Yao's calendar efforts, is noted, in its introduction, as a document not contemporaneous with the events that it recorded.

In fact, the text about a year of 366 days and the intercalary month proves that the documents were amended or corrected after 747 BC when the year changed to a value close to 366 days and an intercalary month would be needed to bring the months in tune with the length of the year. It certainly was not contemporaneous with Yao, when the year would have been 260 days long. The only thing I would feel confident about is that a calendar revision was made circa 2350 BC.

The first Chinese historical records were written after circa 2200 BC (the first

contemporaneous statement of the Shu is in 2197 BC by the son of Yu), but woven in are a confused recollection of a series of earlier Gods.

Yao and Shun can be identified with some certainty. Yao is Jupiter as the Midnight Sun, the later Re of the Egyptians. He appears before the "flood of 2350 BC" (which is mentioned twice in the *Annals of Shu*), and which matches my assumption that Jupiter developed a coma after exiting from the asteroid belt, perhaps at about the time of the 5th Egyptian dynasty (2550 to 2500 BC) when the Egyptian pharaohs add "Re" to their names. But the coma disappeared before 2349 BC.

The recreated chronology by Chinese scholars in about 200 BC holds that Yao died in 2257 BC, 30 years after having shared his throne with his follower, Shun. Shun first shows (is born) in about 2310 BC.

Shun is the Moon, which by my estimate first showed perhaps at the time of the fall of the Absu, which the *Annals of Shu* describe as waters "standing up to the heavens." The *Annals of Shu* also records activities for Shun, each one of which takes exactly a month, and which frequently start on the first day of the month. Shun spends a great deal of time traveling on inspection trips. We could not be told more plainly who Shun is. Both Yao and Shun are referred to as "Tis," that is, "Gods." The next ruler is Yu, a human selected by Shun. Yu is listed as a "king" (a potentate over an Earthly region) and not as an "emperor" (the sovereign over all of the world). An "emperor" does not again appear in China until 2000 years later.

Hindu Parallels

Hindu sources are overwhelmingly vast, encompassing thousands on thousands of pages of poetry, often in competing and contradictory tracts. Additionally, all the doings of the earlier Gods have been heavily anthropomorphized, so that much of the texts read as if events actually happened in recent antiquity and took place in the lands of India. In the poem *Mahabharata* the Bharata battle is essentially the War of the Gods, as I have noted elsewhere, and is by some dated as starting in 3037 BC.

Others, for example S.B. Roy and K.C. Varma in *Mahabharata and Astronomy*, a chapter of "Mahabharata, Myth and Reality" (1976), attempt to place the Bharata battle by calculating when the Pleiades would have stood at the horizon at the equinox heliacally with the Sun. They arrive at a date of circa 1432 BC by calculating backwards. This suggested date has led to extensive attempts to validate the battle through archaeological finds, with no results.

Other revealing information occurs in the *Bhagavad Gita*. Kelley Ross writes:

"The most important feature of the cult of Vis.n.u is the belief that he periodically causes himself to be born as a being in the world. He does this out of compassion, and this is probably responsible for his epithet as the 'Preserver.'"

"In the cycle of time within which we live, called a Mahâyuga (either 12 thousand or 4.3 million years), there are supposed to be ten Incarnations (or Avatars) of Vis.n.u. Nine have come already: (1) as the Fish, (2) the Tortoise, (3) the Boar, (4) the Man-Lion, (5) the Dwarf, (6) Parashurâma, (7) Rama (of the Ramayana), (8) Kr.s.n.a (Krishna, of the Mahabharata), and (9) the Buddha."

"As the Buddha, however, Vis.n.u is supposed to have taught a deliberately false doctrine (which is how Hinduism always sees Buddhism), to destroy demons. The tenth Avatar, Kalkin, will usher in the end of the world (or the end of the Mahayuga)."

-- Kelley Ross at www.friesian.com/gods.htm

Neglecting the long time spans (which Hindu texts are especially given to, often to correct for lapsed predictions of periods from older sources), you will note again the eight appearances of Vishnu, with Buddha added at a much later date, and the promise of a tenth appearance. This looks like a conflation (as with many other people) of the eight visits of Mars before 3147 BC, and the ten visits afterwards. Included in the appearances are the very early "fish" and "tortoise," likely dating to the era of the southern plasmoids.

The Calendar

The following table is a summary restatement of the days in the year during various periods, and the estimates of the days in a month (a lunar orbital rotation), if there was a Moon.

The text will explain how calendars varied over the ages, and how different people made adjustments to old calendars to meet new conditions. This information brings together data distributed over the texts of previous chapters and endnotes and adds some additional information. Hopefully, you will be able to make sense of the many calendars in use throughout the world, and why these changed.

The radius of the Earth's orbit has varied over time since 3147 BC. Additionally, the orbit was certainly more eccentric at earlier times (which does not change the orbital period). During most eras (except the last two) the orbit of Earth probably swung out to as much as 0.9 AU at aphelion. At perihelion Earth would have had to travel to well within one half AU in order to have the short average solar years listed below. Thus the "days per year" shown below cannot be translated exactly into an equivalent distance from the Sun based on a nearly circular orbit, as we have today. It would only be an average.

Solar Year Variables					
period (BC)	days per year	days per month	months per year	orbit (AU)	era and notes
10900 - 8347	?	--	--	?	First Creation
8347 - 3147	225	--	--	0.72	Second Creation
3147 - 2349	240	--	--	0.75	Old Kingdom

2349 - 2193	260	26	10?	0.79	Fall of the Absu
2193 - 1492	273	27, 28	10	0.83	Middle Kingdom
1492 - 747	360	30	12	0.99	New Kingdom
747 - today	365.24	29.5	12.38	1.00	Current Era

The "Kingdoms" refer to well-known Egyptian eras.

10900 - 8347 BC, the "first creation"

In the thousands of years before 3147 BC the Earth's orbit was determined by the path which Saturn took around the Sun. But apparently the Sumerians kept a count of days during this period. It is doubtful if either they or anyone else kept a calendar, or even felt the need to. The Sumerians (or their predecessors in Northern Mesopotamia) had been keeping accounts of agricultural products since 8000 BC, and would have been perfectly capable of a tabulation of this sort, even though it ran to a numerical value of 162,000 -- a numerical value held by some as representing years, judged to be nonsense by archaeologists, but thought by me to represent days.

The Olmecs were counting years since long before 10,900 BC, but called the event of the shadow of 10,900 the "first creation." They counted in years called Tuns, double decades called Katuns, and sets of 400 years, called Baktuns by us and "400" by them.

An isolated page of the *Chilam Balam* mentions conditions before 10,900 BC, possibly reaching back to 17,000 years ago, equivalent to the European Magdalenian period, and earlier to perhaps 41,000 BC. But of course nothing is identified by years, but only as very long periods of time.

If, as I suspect, Earth was carried away by Saturn a number of times in the last 40,000 years (as Tom Van Flandern's gravitational theory allows), then Earth would have experienced a series of variable years, with aphelion far from the Sun, and infrequent plasma stream contact with Saturn. This would explain the apparent long years before about 10,900 BC (see the Carbon-14 section further below), and the inexplicable series of glaciations.

8347 - 3147 BC, the "second creation"

A 225-day year is obvious from the "kings before the flood." It is the only close orbit that fits the data. It would have been in effect from 8347 BC to 3147 BC, and during all of the "Era of the Gods" (4077 BC to 3147 BC). The equivalent orbital distance from the Sun would have averaged 67.5 million miles (108.7 million km, 0.72 AU), but likely Earth was still traveling much further away as part of its elliptical orbit.

The Sumerian record was most likely recorded in days. Again, except for this record we have no data on any sort of calendar system in use anywhere, although the Egyptians have a record of the "lifetimes of the Gods" in years (but these, as also in China, often run simultaneously). The Maya *Chilam Balam* books record the interactions of planets for this period, and even

speak to the electric eruptions of Saturn (as does the *Popol Vuh*), but provide no tallies of year counts before 3147 BC.

3147 - 2349 BC, the Old Kingdom

The 240-day year was originally found by inspecting of the data of the "kings after the flood," but it can also be inferred from the remnants of calendars in use in the following era (as in China which divides the year up into four 60-day periods). The 240-day year would have been in effect from 3147 BC through 2349 BC. The equivalent orbital distance from the Sun would have averaged 70.3 million miles (113 million km, 0.75 AU).

This period starts with the massive flood from the South Pole. This was the most monumentally disruptive event in history. All the previous celestial displays had been well away from Earth, and could be neglected. The flood changed that. Here was a separation between "before" and "after," and it is little wonder that many people now show a concern with the passage of time, and start tallies of days and years.

Within fifty years the Egyptians start an annual record of Gods or God-pharaohs. The calendar is annual, and years are named after religious festivals or other accomplishments. The years are without notation of seasons or months (there was no Moon yet).

The city of Kish in Mesopotamia similarly keeps track of Gods or God-kings by "years" (or some indeterminate measure of time). In only one instance a "month" is indicated in the record, but it seems to be an error, or may have been meant to signify a fraction of a year and was added at a much later date.

The predecessors of the Maya were counting in Tuns ("stones"), which are years, and in Katuns, which are twenty-year periods, and in a larger measure of 400 Tuns, known (to us) as a Baktun. Certainly a record of years was kept, likely in terms of the larger blocks of 20 years and 400 years, for in the 16th century AD the Maya *Chilam Balam* will be able to correctly specify the Katun of almost all of the celestial events since 3147 BC which we know from the Eastern Mediterranean.

The Classical Maya sculptures at Palenque (circa AD 700) correctly date planetary incidents in the past -- 3000 years earlier -- from a record which must have been known as familiar history to the sponsor of the sculpture as well as the leaders of neighboring ceremonial centers. Similarly, when the Olmecs instituted the Long Count in 747 BC, they were aware that six Baktuns (2400 solar years) had already lapsed since the beginning of the current creation. See the chapter "The Maya Calendar," for more details.

The Olmecs, Maya, and their predecessors, kept a running calendar longer than any other people on Earth. Despite the Egyptian records of regal years dating from shortly after circa 3050 BC, we are not sure today how closely the "years" of the pharaohs matched actual solar

years, since the count of years was restarted with the accession of each pharaoh, and it is not clear when a new pharaoh was invested after the death of the previous one. Later Chinese kings (in the next era) similarly did not count the first three years of a reign, at the start of accession, until later in history.

The calendar of the Mesoamerican people was divorced from the personalities of leaders, had a solid base-5 and base-20 counting system, and was built around a modern conception of what an "interval" constituted, unlike the Sumerians whose early chronologies do not add up (and overlap) or even the much later Romans who still counted the passage of time as if it were a set of objects.

The initial Mesoamerican calendar divided the year into 12 seasons of 20 days. This may have constituted an agricultural calendar, allowing 20 days for seeding, weeding (a number of times), the breaking of corn stalks, and the eventual reaping. Each of the 20 days received a name, which continued in use for the next 5000 years. This is almost certain, because there is no logical transition to the Tzolkin calendar after 2349 BC except to suggest the very early establishment of the rotation of 20 named days.

From China we get a clearer indication of an archaic calendar system, but of course as remnants retained at later ages. China seems to have had a calendar based on dividing the 240-day year into four seasons of 60 days each. China, unlike Mesoamerica, Egypt, and Mesopotamia, had distinct seasons. This division of the year into 60-day periods remained a standard for 5000 years. Both the four seasons and the 60-day periods remained in use. Even after the Moon arrived in 2349 BC, the months were associated with the 60-day seasonal divisions.

2349 - 2193 BC, after the fall of the Absu

This period starts with the "flood of Noah," and the first appearance of the Moon. The Moon stabilized within an estimated period (by me) of 35 years. It is at this time that we see the first indications of calendars in widely separated regions of the world. The Earth is now 74 million miles (119 million km) from the Sun (0.797 AU), and the year had extended to 260 days.

The regular appearance of the Moon became the calendar, signaling to everyone the days for religious festivities. There were, during this first period after the fall of the Absu, ten months of 26 days each. At the end of ten months, the year and the cycle of religious observances started over.

The 260-day year is an acknowledged number which shows up in Mesoamerican sources as the Tzolkin calendar. The *Chilam Balam* makes specific mention of the addition of "days of the year" at this time. The earlier Mesoamerican calendar of 20 days was at this time augmented with the addition of a simultaneous rotation through 13 days, started in this

period. This is the Olmec and Maya Tzolkin calendar.

The rotation through 13 numbers represented the period from a new moon to a full moon, and from full moon to a new moon. A complete rotation through 20 and 13 also distinctly named and numbered each day of the 260-day year. The Mesoamerican Tzolkin calendar is still in use today in parts of Guatemala, the Yucatan, and Southern Mexico.

In China one of the last of the mythological emperors (Gods), and the first to enter recorded history, Yao (who is Jupiter), instituted the calendar which was used by the Xia and Shang dynasties. So says the historical record, the *Annals of Shu*. But the *Annals*, gathered together in the 8th century BC, speak of Yao establishing a 366-day year. This emendation to the historical record was thus made after 747 BC, but before 685 BC, since Yao also tells his astronomers that the Pleiades mark the equinox. After 685 BC, this last was no longer true.

The new Chinese calendar continued the 60-day periods, but added the day of the lunar month to specify actual dates.

In the Babylonian creation epic, the *Enuma Elish*, the God Marduk (Jupiter) also establishes the calendar after the demise of the Absu.

2193 - 1492 BC, the Middle Kingdom

A second change in the Earth's orbit happened in 2193 BC, when the Akkadian empire failed and the Old Kingdom of Egypt came to a close. Worldwide there was a lack of rain, or a lack of light, lasting years. Mesopotamia and Egypt (and other locations) took up to 200 years to recover.

The Earth was now 77 million miles (124 million km) from the Sun (0.83 AU). The year went to 270 or 280 days (probably 273 days). I suspect that the number of months in the year stayed at 10, each approximately 27 or 28 days long. Mesoamerican culture accommodated this easily by extending their 20 by 13 Tzolkin calendar by another cycle of 13 days, and just ignoring the fact that their annual calendar was now 13 days short. Other people apparently adopted 10 months of 27 and 28 days to fill the year.

Mesoamerica divides the visible south sky into "13 zodiac divisions" of 21 days each (totaling 273 days). The 13 divisions will remain and will surface again in Classical Maya times (as the *Paris Codex* shows), but the periods of each of the 13 constellations will lengthen to 28 days by the time we reach our era, adding up to 364 days.

During the Shang dynasty (1700 to 1100 BC) there are oracle bone records which record a 27- and 28-day lunar period. The Shang (apparently) also maintained a calendar based on multiples of 60 and 10. It seems to be a holdover from a previous era, when there were 240 days in the year, but not 10 months yet.

The Chinese also established "28 lunar mansions" across the dome of the stars to track the Moon. It may be an amazing coincidence (although it should not be) that the Vedic Indians (who had no contact with China during this period) do the same. The Indian notion of "28 lunar mansions" has lasted in Indian astrology to today.

1492 - 747 BC, the New Kingdom

After 1492 BC the Earth's orbit increases significantly, to 0.99 AU. The 360-day year is a clear certainty from many records, and in effect up to 747 BC. The equivalent orbital distance from the Sun would have averaged 92.1 million miles (148.3 million km). There were 12 months of 30 days.

The 360-day year is so well established from so many documents, that some researchers today just take it for granted, although students of antiquity have to apologetically add, "plus the five days," or make excuses for the people of this era with statements like, "they used an idealized year" or "they could not count." What an amazing statement! Counting would have been the highest science of the human intellect since the Paleolithic.

The Egyptians had apparently established a calendar after 2349 BC or 2193 BC. In this era (after 1492 BC) that they divide the dome of the stars into 36 segments to mark time (at night), which later became known as "decans" by the Greeks, because they are 10 degrees apart across a 360-degree sky. These are first shown in the tomb of Senmut, 1493 BC (circa 950 BC in new chronology), the Calendar Registrar and Vizier to Queen Hatshepsut. Senmut's tomb, however, still depicts the months as having 24 days -- in accord with the much older calendar after 2349 BC. (These divisions are not our "hours" since decans were used at night, and the day was divided into 10 equal portions.) Commentators on the sculpture of this tomb simply neglect to mention or explain the division of the 12 month circles into 24 parts. [\[note 21\]](#)

Babylonians establish 18 divisions of the ecliptic, of 20 degrees each, thus also 360 degrees - or 360 days. The passage of every three divisions of 20 degrees (days) represented two months of 30 days. The 360 degrees of circular measure that we use is based on a long period of time when there were 360 days for a complete circuit of the Sun. China apparently also divided the ecliptic into 360 degrees. These divisions of the sky reflect the fact that the year was 360 days, not 365.25 days. China changed its division of the sky to "365.25 degrees" some time after 747 BC, when the year became longer, and kept this in effect until about AD 1500.

"During the Shang Dynasty [1700 to 1125 BC], the Chinese had in place interlocking cycles of 10 days and 12 days; together, these made a cycle of 60 days. This 60-day cycle was kept, apparently continuously, for thousands of years. Astronomical events recorded by the Shang Dynasty people were noted by the place in the 60-day cycle, as well as the lunar month and reign year. With this information on several lunar eclipses,

there have been attempts to correlate the Shang calendar with our Christian calendar, but these attempts have not been successful."

-- <http://www.astro.virginia.edu/class/chevalier/astr341>

The Shang calendar records, mentioned above, date to after 1500 BC. The 60-day periods cannot be squared against the day count and month count of the previous period (the 273-day year), but it elegantly suited the configuration of the heavens which took effect after 1492 BC. It is likely that the Shang "60-day period" at that time reflected a double lunar month period, similar to the Babylonian division of the year. It is also likely that this represents a month-like division of the synodic period of Venus.

We cannot neglect Venus as a "marker" for calendar use, especially when it is noticed that many nations adopt an awkward "Venus calendar" as a means of resolving the new length of the month and the new length of the year after 747 BC. Venus would represent a stupendous sight at its heliacal rising or setting. Unlike any other planet or star, which all but disappears in the glare of the Sun or the haze of the horizon at heliacal rising or setting, Venus, at its heliacal rising (and in reverse order at the heliacal setting), would show the tail of its coma initially directed toward Earth, and thus as a bright light, and then, as soon as it cleared the Sun, the tail would expand to sweep straight up into the sky over the next few days. The "going up of Sothis," as described by Egyptian records, is not simply the appearance of Venus, but describes the spectacular levitation of its tail. It is a marker much easier to determine and much more visible than the equinox of the Sun or the periods of the Moon.

During the period of 1492 to 747 BC, the synodic period of Venus would have been exactly 600 days. The rising and setting of Venus would only fall back into sync every eight Earth years ($225 \times 5 - 360 \times 8 = 0$). Six hundred days is ten 60-day periods (equal to twenty lunar months). But it is unlikely that the start of, for example, the heliacal rising of Venus would have coincided with the lunar month. For this reason the Shang continued to keep track of the 60-day periods and months separately.

Calendars are very conservative, and they are not easily changed. Thus, although the number of months in the year during this era expand from 10 to 12, numerous people throughout the world steadfastly maintain a year of ten months into the 20th century AD (3500 years!), making adjustments to the solar year by, for example, expanding the last month to 90 days or repeating it twice.

Saner people adopted the lunar month as the calendar, although in some instances at the value of the previous era, 28 days. This then became a "calendar month," resulting in the need to intercalate additional months periodically if the calendar was to keep in sync with the apparent lunar months. The Babylonians elected, additionally, to start the year with the spring equinox of the Sun. I would suggest, in fact, that this coincided with a new Moon. (This was suggested by Velikovsky and seems correct for a number of reasons.) The new Moon might be a lot easier to spot than the rising of the Sun at the equinox.

The predecessors of the Romans, however, not only maintained the 10-month calendar, but probably rotated through the ten months twice to match the synodic period of Venus. The month count was not rectified until sometime in the era after 747 BC. Roman historians relate that one of the first kings of Rome shortly after its founding (before 747 BC) added two months to the calendar of 10 months. This would only have been needed if the Romans, as I have proposed above, still rotated through sets of 10 months.

If the historians recall the addition of two months to the ten, it would confirm the fact that prior to that time the earlier ten-month calendar was still in use. The two added months, January and February, were added after the last month of the year, December ("Ten") and, like all the other months, were set at 30 days. This must have happened before the length of the year changed again in 747 BC.

747 BC - 686 BC, The Era of Nabonassar

After 747 the Earth assumed today's orbit of 93.2 million miles (150 million km, 1.0 AU), and a year of 365.24 days. The Moon changed its period to 29-1/2 days. There were now slightly more than 12-1/3 lunar months in the year. This would cause no end of problems, for the lunar months no longer coincided comfortably with religious feast days in the solar year.

In other endnotes I have shown how the extra days of the year were elegantly distributed to the months of the year by the Romans. Also, in the chapter "The Maya Calendar" I have detailed the start of the Long Count of the Olmecs.

686 BC - present, The Current Era

The jolt by Mercury in 686 BC made no significant change to the year of Earth, but may have reduced the Moon's period to its present value.

In about AD 200 the Greek writer Plutarch, in *Concerning the Mysteries of Isis and Osiris*, to explain why the Egyptians had five intercalated days after the year (which celebrated the birthdays of the Gods), sets forth:

"Hermes ... playing at draughts with the moon, won from her the seventieth part of each of her periods of illumination, and from all the winnings he composed five days, and intercalated them as an addition to the 360 days".

This cannot be calculated by any method to produce the extra 5.25 days. As one 19th century translator, G.R.S. Mead, notes, "This is an exceedingly puzzling statement." However, Patten and Windsor, in *The Mars-Earth Wars* (2003), calculating backwards rather than forwards, offer the following:

"In that celestial crap shoot, the Moon lost 1/70th of her holdings, or its period, while

the winner, the Earth gained a similar 1/70th of its day count per orbit, an addition to its former orbit period."

"The Moon's modern period is 29.53 days. 30 days minus one part in 70 is 29.57. Plutarch was within .04 day of being exactly correct for the new lunar period."

"The Earth's new period, 365.256 days, less one part in 70, results in an earlier period of 360.038 days. Here again Plutarch's explanation was within .04 of a day of being exactly correct. Plutarch's ancient Greek sources were solid, and his explanation for the new conditions satisfied his Roman audiences."

Plutarch here deals with the Earth shock of 686 BC, but makes the comparison to the year before the Earth shock of 747 BC. Patten and Windsor claim that Plutarch confuses Mercury (Hermes) with Mars (Ares), but there is no confusion of Mars and Mercury by Plutarch. He clearly states that it was Mercury who made the last adjustment in the Earth's orbit.

I am not sure if the ancients dealt with orbital periods to the third decimal place. 1/70th seems like an awkward fraction of 360. But in that we do not really know what change in the orbit was made in 747 BC, it is difficult to judge how the 1/70th should really be applied.

I have no idea of the correct value for the length of the year during the 60-year period from 747 BC to 686 BC, except to suggest that it was perhaps slightly longer than 365.24 days. This is based only on a curious statement in the *Annals of Shu* which tells of Yao's calendar efforts, which involved the declaration that the year consisted of 366 days. I'm sure the statement (which has nothing to do with the actual length of the year in 2349 BC) was meant to bring ancient documents up to date. This was also done with regard to the location of the equinoxes. What this suggests is that these "corrections" were made to the texts of the *Annals of Shu* after 747 BC and before 686 BC. With the change in the heavens in 685 BC, the "corrections" were not again corrected. It was clear at that time that they would have to stand as the record of remote antiquity. The *Annals of Shu* were compiled, it is estimated, in 700 BC.

With the Moon on an odd interval of the year, religious festivals which had been signaled by visible aspects of the Moon, like the new Moon or the full Moon, now drifted around the year. Religious feast days fell 9 or 10 days behind with every following year. Calendars were changed again worldwide. The solutions varied immensely. I have detailed some of these changes in the chapter "Destructions by Mars."

Carbon-14 Radiometric Dating

A comparison is made below of real time (solar years) and Carbon-14 elapsed time (years of 365.24 days) after corrections. The table below is from the standard "date correction" tabulation currently in use (1998). Of interest is the table's "difference" between actual and

Carbon-14 dates, compared with "calculated" dates based on what I presume to be the actual number of days in a solar year.

Raw Carbon-14 dates are based on the exponential decline of residual radioactive Carbon-14 in samples of plant carbon (composed mostly of Carbon-12). The raw data thus generates "time" as "365.24-day years." It had been assumed at first that there was a direct relationship between lapsed time as determined by the Carbon-14 measurements and real time measured in current years. This assumed both that the amount of radioactive carbon produced in the atmosphere was constant over time, and that the year has always been of the same length.

The residual Carbon-14 in a gram of (mixed) Carbon can be measured by counting the number of electrons released per minute as the Carbon-14 decays to Nitrogen-14.

This relationship was shown to be somewhat in error in the 1950s. The uncorrected Carbon-14 results always gave dates later in time (that is, younger) than the actual dates for some well-known (dated) samples. It was concluded that there were periodic fluctuations in the C14/C12 mix of carbon dioxide in the atmosphere. The raw Carbon-14 results at first were corrected by a small percentage for dates prior to 700 BC when certain well-dated artifacts did not yield the correct Carbon-14 dates. Ultimately corrections were made on the basis of the Carbon-14 analysis of tree rings. That solved a lot of problems, for trees do not lie about their age. For dates before about 8000 BC (the oldest tree ring data available) the Carbon-14 tables are based on data from coral cores at Barbados.

The tree rings constitute an absolute and indisputable measure of time as a count of solar years, although it says nothing about the length of the year in days. Carbon-14 can be measured for tree rings, but varies with locations and local climatic conditions, of course, and thus yields a range of Carbon-14 measurements for any actual year. As a result we end up with a table where the "actual date" is the independent variable, as shown below, rather than the dependent variable.

In the past before 700 BC, all the Carbon-14 derived dates are earlier than chronological dates, that is, younger than the actual dates. This is attributed, as I have pointed out, to variations in atmospheric Carbon-14 levels. But it could also be because the years at various times were shorter, especially before 747 BC.

The tabulation below compares my estimates of the number of days in the solar year with the corrected Carbon-14 data. The calculated dates are on the same order as the corrected Carbon-14 dates for the time span of 4077 BC to 747 BC. That is, my calculated date corrections are in line with the fluctuations of the Carbon-14 dating technique. I am comparing my "calculated difference," which represents the complete shortfall in years, against the "Carbon-14 difference," which is only the difference in years between the uncorrected Carbon-14 time and the specific calendar year. The two columns are thus not exactly comparable.

For the time before 4077 BC, the calculated dates do not match the corrected Carbon-14 dates if it is assumed that a 225-day year was in use. I would have to conclude that for this prior period the year could not have been 225 days, but was perhaps twice as long.

The tabulation below is annotated with the changes in the length of the year.

The full "INTCAL98" Carbon-14 correction table lists data at 50-year intervals from AD 1955. I have only shown some selected years which coincide with changes in the length of the year. The original table also includes measures of the standard deviation, which I have neglected in the tabulation below.

* -- indicates estimates based on this chronology
The calculated difference in years, for example, for 4075 BC =
((1495 - 745) * 5.25
+ (2195 - 1495)* 92.25
+ (2345 - 2195)*105.25
+ (3145 - 2345)*125.25
+ (4075 - 3145)*140.25) / 365.25 = 862 years
BP -- before the present
-- estimated length of the year based on Carbon-14 dates
May 2009: revised for change to 3147 BC.
May 2015: revised for change to 4077 BC.

A few observations follow:

- Comparison is between the two columns "calculated difference" and "C-14 difference, years."
- The tables use AD 1955 as a base date, so that a conversion to "Solar BP" (Before the Present) from "BC/AD" requires adding 1955.
- I have shown the INTCAL98 table in reverse order.
- Note that for two selected dates, AD 1705 and AD 405, the error correction is plus and minus some 100 to 150 years. This type of variation is not unusual for most of the table up to about the 8th century BC. I have used the following as "near" dates:

year of orbital change	nearest INTCAL date
747 BC	745 BC

1492	1495
2193	2195
2349	2345
3147	3145
4077	4075

- My calculated dates for the period during which I have postulated differences in the length of the year are mostly in agreement with the corrections of the table, back to 4077 BC.
- We know of periods during which massive forest fires raged over parts of Europe. The table would account for these, so some of the variation could well be attributed to Carbon-14 variations. The actual table also shows the effects of the Industrial Revolution (not shown here).
- Similarly, the contacts (smells of perfumes) with Mercury between 806 and 686 BC could have altered the C-14 proportions of Earth's atmosphere at that time. This may be why the calculation by length of the year underestimates the C-14 year data after the 8th century BC.

Saturn in the Precambrian

I will assume that Earth orbited about Saturn, rather than the Sun, during all of the Precambrian (3.8 billion to 560 million years ago) and through the Permian (ending 250 million years ago), after which time Earth was captured by the Sun.

It is the chronology of the Precambrian I want to discuss here. Simply stated, it looks as if both the geological changes and the biological changes occurred at 600 million to 700 million year intervals. Assuming that the biological advances (increases in complexity) require the catalyst of a massive plasma contact, I'll assume that Saturn went nova at approximately 700 million year intervals. The first of these might have created the Earth in a mass expulsion 3.8 or 3.9 billion years ago (bya). A table follows. I am using dates for the Canadian Shield because it is the most studied.

Sedimentation and lava are first noticed in geological formations dated 3.8 to 3.2 billion years ago. This seems to indicate that the Earth possessed winds and water from a very early time (volcanoes produce water).

Geological Dates for the Canadian Shield (dates vary somewhat for Australian and African records)		
age of the Earth in billion years	geological events	biological events
-----	-----	-----
3.8 (3.9)	(mass expulsion)	earliest dated rocks
3.1 (3.4*)	Kenoran Orogeny	first microscopic prokaryotic cells
2.39 (*)	Diabase dikes	prokaryotes continue
(2.5 -2.4)	African Great dikes	
1.64 (*)	Hudsonian Orogeny	first eukaryotic
1.2 (*)	Duluth Grabbo (Fraser Range*)	(- alternately dated)
0.88 (0.85**)	Diabase dikes	first multicellular
0.56	Cambrian	life with solid parts

0.25	Permian	Permian extermination
0.00 (4077 BC)	"Creation"	low-level changes
* Australia also		
** Australia and Spitsbergen		

An interesting parameter is the spacing between major geological activities for the Precambrian. The following tabulation points that up:

3.8 (0.7) **3.1** (0.6) **2.39** (0.71) **1.64** (0.75) **1.2** (0.44) **0.88** (0.32) Cambrian: **0.56** (0.31)
Permian: **0.25** (0.25) "Creation" **0.00**

read this as, **date** (interval) **date**
[time in billions of years]

The numbers in parentheses, above, show the intervals between periods of geological activity or the start of biological periods. I have extended the tabulation to the era of "creation," 4077 BC.

The date of 3.9 or 3.8 billion years ago marks the "birth" of Earth. The end of the first interval of 0.7 billion years is marked by the first signs of prokaryotic cells appearing at about 3.1 billion years ago. The average interval through all of the Precambrian is 680 million years (counting the last two intervals before the Cambrian as a single interval of 0.76 billion years). After that the interval between mass expulsions (nova events) decreases, and in fact the shorter interval appears already before the Cambrian.

I may actually be misreading the interval, first because the creation of the Moon seems to be dated to 4.3 bya and thus 400 million years before the birth of the Earth at 3.8 or 3.9 bya, and not at the expected 700 million year interval. This would be significant if the Moon is a Saturnian planet. Secondly, I have excluded from the list above an event dated at 3.4 bya, which would also decrease the earlier interval to 400 million years.

The concluding date for the Precambrian is 0.57 bya (570 million years ago) -- the start of the Cambrian. This is a matter of nomenclature, although it is generally held that this date follows on another massive disturbance. Otherwise there is no sharp division between the two periods. The Cambrian is defined as the sudden appearance of organisms (fossils) with hard body parts.

When I first looked at the above table I suddenly had the realization that Saturn might be due for another nova event right about now. Then I realized that this had happened already -- in 4077 BC.

The extinction at the end of the Permian, 250 million years ago, has been well established for marine biology -- 99 percent of marine species were lost. More recent research has established that this was accompanied by seven land-based upheavals (during which 95 percent of land species went extinct). The data encompasses South Africa, China, and some other locations, and is spread over an estimated tens of thousands of years. This matches my

earlier proposal that it would take 15,000 years for Saturn to enter and again exit the Sun's plasmasphere (biologists suggest 10,000 years for the duration of extinction events).

This long land-based Permian extinction has all the marks of a nova event. From biological considerations, it is probable that Earth was still in orbit around Saturn through the Permian. The extinction at the end of the Permian also looks like it is the result of a series of equatorial strikes and perhaps a continuous immersion of Earth in plasma flows. The date of the Permian extinctions fits well with the decreasing intervals between nova events, which had halved (from 700 million years to 440 and 320 million years) already before the Cambrian.

1.2 (0.44) **0.88** (0.32) Cambrian: **0.56** (0.31)
Permian: **0.25** (0.25) "Creation" **0.00**

Meteorites

The meteorites identified as "Martian" (the SNC series) have a solidification date of 3.1 bya. Moon rocks are generally dated to 4.3 billion years ago (but also to 3.1 bya), which hints at the Moon's Saturnian origin by having an age displaced from the age of Earth or Mars by a multiple of 400 million years.

The separation dates of meteorites (as different from the "solidification dates") are based on a method of radiometric dating which depends on the supposition that meteorites have been subjected to a constant bombardment of high energy Gamma rays from outer space (which come from beyond the Solar System, and thus is constant) since their separation from a parent body, thus transmuting some of the elements, which can be measured. These tests yield "separation ages" -- the time when the parent body of a meteorite broke up.

There is an interesting coincidence of the separation ages with other events I have proposed. The separation ages of chondrite meteorites -- 3.2 million years ago (mya) and a tail to 40 mya -- coincide, or precede, the extinction (and glaciation) of 30 million years ago and the glaciation of 3 million years ago.

The Martian SNC meteorites have separation dates of 11, 2.6, and 0.5 million years ago. These would seem to correspond to the earliest evidence of northern glaciation (11 mya) and the well-defined start of northern glaciation (2.6 mya). The separation date of 0.5 million years ago may relate to the start of the most recent glaciation. It is of course uncertain how these separation dates of rocks from Mars relate to a history of the Earth, unless it were to be assumed that Mars had already been captured by Saturn as early as 11 mya.

I would thus have to suggest that the separation date of 0.5 mya might represent the capture of Mars by Saturn, and that the cup-and-tail markings of the Upper Paleolithic could have been extended much further back than 40,000 years in time -- 500,000 years into the Middle Paleolithic where only Homo erectus was the constant witness.

Iron meteorites are dated (depending on the sub-variety) at 100 to 200 mya, 100 to 300 mya, and at 500 to 700 mya. The first two dates coincide roughly with the Permian extinctions; the last set of dates corresponds to the extinction just before the Cambrian. Tom Van Flandern has noted that older meteorites will not be found, since they will have dispersed since their original breakup. Iron meteorites represent only a very small percentage of recovered meteorites. [\[note 22\]](#)

If we put together what we know of other planets and the creation and breakup dates of meteorites, we have the following tabulation:

- Neptune, Uranus: unknown
- Iron Meteorites: 4.4, 4.6 billion years ago
- Moon: 4.3 billion years ago
- Earth: 3.9 billion years ago
- Mars: 3.1 billion years ago
- Mercury: unknown
- Iron meteorite breakup: 500-700 mya (late Precambrian)
- Iron meteorite breakup: 100-300 mya (Permian?)
- Chondrite meteorite breakup: a tail to 40 mya (last extinction)
- Chondrite meteorite breakup: 3.2 mya (last glaciation)
- SNC meteorite breakup: 2.7 mya (start of northern glaciation)
- SNC meteorite breakup: 0.5 mya (start of last glaciation)
- Venus: 6,000 years ago (4077 BC)

I should add a few notes: By "gas retention" dating methods, some iron meteorites date to before the creation of the Solar System -- as it is held to be today (4.7 bya). But when this method is applied to stony (chondrite and achondrite) meteorites, dates range from 4.0 to 4.5 bya. From another source, iron meteorites peak also at 630 and 900 mya, others distribute from 150 mya to 2 bya. [\[note 23\]](#)

There are problems with dating, for it is held that the Solar System is 4.7 billion years old, and the dates of all meteorites and planets are arranged to asymptotically approach this figure, even when this is illegitimate. Older dates are preferred as representative of the age of a planet. For example, the age of the Moon is held to be 4.3 billion years, yet the rocks brought back and analyzed came in at 3.2, 3.7, 3.8, 4.2 and 4.6 billion years. At best this data would suggest that parts of the Moon's crust were still boiling out liquid magma more than a billion years after its creation, which is unlikely.

Endnotes

Note 1 --

Most of my text has blandly ignored the difference between astronomical years, Julian years, extended Gregorian years, and Eastern Mediterranean chronology. The following is how various year tallies relate:

- Astronomical years use the Julian calendar backwards from circa AD 1500, but use a year "zero" to fall before AD 1. Astronomical years in the previous era are thus equal to Julian calendar years less one year. For dates in the previous era the astronomical calendar uses signed years, like "-747" -- which would actually represent 748 BC on the Julian calendar.
- Julian years are based on the assumption that the solar year is 365.25 days long. It accounts for the 1/4 extra day per year by introducing a leap year every four years. There is some shuffling back and forth in placing dates at the exact time of the solar year because some years are longer or shorter by a single "leap day." The Julian calendar had been in use (as mandated by Julius Caesar) from about 40 BC (but correctly only since about 5 BC) to about AD 1500.
- Julian years are slightly longer than Gregorian years, and start to move a day or so further into the past every 400 years from about AD 1500 (from an initial divergence of 10 day). A Julian calendar is used in astronomy and, when used for the previous era, is based on a "Julian Day" count which was developed in the late 16th century AD.
- The Gregorian calendar has been in use since about AD 1500, and accurately places all dates in the proper season of the year, although with some displacement of dates like the Julian calendar due to leap days. To stay in sync with solar years, the Gregorian calendar neglects (skips) a leap day every 400 years.

- Julian years and dates, which tend to drift backwards in time, can be converted to equivalent (backward extended) Gregorian dates. This will place the dates in the proper season, which generally is my only concern.
- The Julian to Gregorian conversion routine which I am using recalculates the Gregorian year dates for every year in the remote past based on the extrapolation of various celestial parameters. The conversion should be very close to actual equivalent days in the solar year, as long as the seasons and the length of the year have not changed.
- Of course, the seasons changed after 685 BC and the length of the year changed in 747 BC (and at a number of other times in the past). Because the extended Gregorian years of the conversion program are recalculated each year, it is reasonably accurate as an indicator of where a day in the year would fall even when used for years in the past before 685 BC or 747 BC. The Gregorian year can be apportioned over a year with fewer days.
- The Eastern Mediterranean chronology is based mainly on the *Babylonian Chronicles* (the "Era of Nabonassar"), and used extensively by astronomers since the time of Ptolemy. But it is four years advanced over astronomical chronology. This is easy enough to correct most of the time by subtracting four years. This correction is apparently not needed before about 700 BC, or dates after the Roman era.
- Babylonian dates are based on calendar months of uncertain lengths, although historians assume some variation in calendar month lengths which would average to the lunar month. Extra months were intercalated since 747 BC. Most other nations in the surrounding region probably used either the Babylonian months (and certainly in the area-wide regionalization by the Assyrians after 740 BC) or attempted something very similar.
- I would expect that the Babylonians suddenly and inexplicably intercalated an additional month after the Venus nova event of 685 BC, to bring the start of spring (the vernal equinox) into the correct month. There are Jewish records also of doubling up on a month sometime in this era.
- The Egyptian calendar remained uncorrected, and after 747 BC three separate calendars were in use. One is a religious Venus calendar of 360 days. Another is an administrative calendar of 365 days. And the last was a lunar agricultural calendar. We know almost nothing about any of these. On the basis of statements found in the *Canopus Decree* of 291 BC it can be suggested when the Egyptians considered a change from a 360-day calendar to a 365-day calendar. See the "Canopus Decree," Appendix I.
- The Chinese used a series of 60-day periods, within which lunar months, and the day of a lunar month, are identified. Dates from these sources have been successfully converted to Julian or astronomical dates in the 19th century AD. Since 747 BC these would have been completely correct. During the 700 years before 747 BC the seasonal dates would have been off by under 2 days if it were erroneously assumed that the lunar months were 29.5 days.
- Dates based on the Maya Long Count (retrocalculated) are also correct to the Gregorian calendar, except for dates before 747 BC when derived by the Maya or by us today. But this last is easy to correct, since the error is an obvious incorrect assumption about the

length of the year in the past. If a "tun" is a year, held to be 360 days (by the Olmecs) before 747 BC, then the difference between our chronology based on extending the current Gregorian years back in time and the Olmec representation, is only a matter of a difference of 5.25 days per year for the period before 747 BC. This amounts to a difference of 34 years to 3114 BC. The correct date for the end of the "Era of the Gods" as retrocalculated under these assumptions is thus 3148 BC. But there is more.

- Besides the error in retrocalculated dates it seems clear that when the Long Count was established in 747 BC, the intent was to represent the past in 360-day Tun years. The five extra days of the revised Haab were not part of the tally. Additionally, if the Olmecs in 747 had meant to just count days in groups of 20s, then the Tun would have represented 20 Uinals (months). Instead, the Tuns are 18 Uinals -- 360 days. Thus the 6 Baktuns which were added to the count of 0.0.0.0 were meant to represent Tun years of 360 days, under the supposition that the Tuns had always been 360 days long.
- The erroneous assumption of 360-day years extending back infinitely can be bypassed by using an "indeterminate Tun" instead. A Tun is a Tun is a Tun, which is a solar year, and the number of days in a Tun does not matter as long as the record of the past used Tuns, not days. This was certainly the case before February of 747 BC (as it certainly was at the time of the Spanish invasion). If we then subtract 6 Baktuns of 400 Tuns (solar years) from 747 BC, we arrive at a true starting date of the current era of **747 BC - 6 * 400 = 3147 BC**. In April of 2009 I changed 400 instances of 3114 BC in these texts to 3147 BC.
- Exact dates, to the day of a year, are confusing in Mesoamerican chronology because of the notion that a day "does not exist" until it is completed, and because there were two chronologies in use, with a difference of two days in the Long Count. This is generally not a problem, except when attempting to correlate dates of the Long Count with dates reported by the Spanish, who were using the Julian calendar, especially when recent translations of these accounts attempt to be helpful by converting to Gregorian dates instead, but without notifying the reader. Note 2 --

There are some 6 copies. Following are notes for a copy illustrated at <http://www.nb.no/baser/schoyen/>

"MS in Sumerian on clay, Babylonia, 2000-1800 BC, 1 tablet, 8,1x6,5x2,7 cm, single column, 26 lines in cuneiform script."

"Context: 5 other copies of the Antediluvian king list are known only: MS 3175, 2 in Oxford: Ashmolean Museum, one is similar to this list, containing 10 kings and 6 cities, the other is a big clay cylinder of the Sumerian king list, on which the kings before the flood form the first section, and has the same 8 kings in the same 5 cities as the present. A 4th copy is in Berkeley: Museum of the University of California, and is a school tablet. A 5th tablet, a small fragment, is in Istanbul."

"Commentary: The list provides the beginnings of Sumerian and the world's history as the Sumerians knew it. The cities listed were all very old sites, and the names of the kings are names of old types within Sumerian name-giving. Thus it is possible that correct traditions are contained, though the sequence given need not be correct. The city dynasties may have overlapped. It is generally held that the Antediluvian king list is reflected in Genesis 5, which lists the 10 patriarchs from Adam to Noah, all living from 365 years (Enoch) to 969 years (Methuselah), altogether 8,575 years."

See the section "Parallel Histories" for my reading of the ten Biblical patriarchs.

[\[return to text\]](#)

Note 3 --

There is a comment by Suidas, a Greek lexicographer of the 10th century AD, who notes that "Saros" meant 222 lunar cycles of 30 days -- a period of 18 years and 6 months on a 360-day calendar and thus 6660 days. This is the cycle of repetitions for the location of the Moon.

Even if the "sars" in the original are taken to have the value of 6660 days suggested by Suidas, the reign years and totals fall into the same range of values as my calculations (see the text), although with double the values. It would change the reign of Alorus from 720 to 1332 years, and the total reign of the 8 kings on Earth from 1072 to 1983 years.

[\[return to text\]](#)

Note 4 --

Mars's northern hemisphere is marked with eight gigantic electric blisters (named "mons" or "tholus"), but no "meteor impacts." The blisters are the result of sustained lightning strikes. That the eight blisters correspond to eight kings before the flood is likely to be a coincidence. The largest blister, Olympus Mons (three times as high as the Himalayas), shows some five separate melting pools.

[\[return to text\]](#)

Note 5 --

The city names or patron gods are as follows:

- Eridug -- is the city of the water god Enki/Ea, probably Eri-dugga, "good city." This is (could be) the cloudbank at the northwest horizon.
- Bad-tibira -- Dumuzid was its tutelary deity. Dumuzid is known as the shepherd, Mars, who guides the dead up the stream of plasma.
- Larag -- dedicated to Pabilsag, the god of trees. This is the trunk of the tree (and occasionally looking like a leaved tree) between the cloud bank and Saturn at the top.
- Zimbir (Sippar) -- its tutelary deity was Utu (Semitic Shamash), the sun-god, Saturn ablaze at the top of the stalk.

- Curuppag (Shuruppak, Uruppak) -- The last king of Curuppag was the hero in the flood story, Ziusudra, the Sumerian Noah -- Shuruppak was dedicated to Ansud, the Goddess of grain. This not only represents the terminal event, the flood, but also the tufts of grain seen waving on the surface of Saturn.

The source of these readings is from L.C. Geerts, [\[www.earth-history.com\]](http://www.earth-history.com). I have added the references to the polar apparition. This suggests that the list of the "kings before the flood" is a later composite of information from diverse sources. The number of the kings probably holds true, for they match the "mythological" records of Mesoamerica, but the names of the cities were added from a description of the polar apparition. There is also "mythological" information from Sumer that Seven Ages expired before the flood (I can't source this, but Geerts mentions it). "Seven Ages" matches information from Mesoamerica, and probably represents much earlier ages dating back to 40,000 BC.

Note 7 --

The later exception is for the third dynasty of Kish:

"After kingship was brought back to Kish again, Ku-Bau, the innkeeper, she who made firm the foundations of Kish, ruled for 100 years as 'king' before Kish was defeated."

"She" is also listed (or translated) as a "barmaid" and as a "prostitute." "She" is probably the planet Venus, but cannot be dated with certainty to the destructive appearance of the planet in 2349 BC, Her "reign" seems to predate Sargon's conquest of Mesopotamia, which was started after that date.

The fact that she is associated with alcohol would date her to 2349 BC, for in both Canaan and Egypt the blood baths (the fall of the Absu) are associated with enraged Goddesses in association with alcohol. The "100 years" is probably 104 years -- two of the 52-year cycles of Venus.

After mention of Ku-Bau, the *King List* is interrupted with a list of kings of Akshak, who together reign 99 years, which is probably simultaneous with Kish, and then continues to the

fourth dynasty of Kish, with the son of Ku-Bau:

"In Kish, Puzur-Sin, son of Ku-Bau, reigned 25 years as king; Ur-Zababa, the son of Puzur-Sin, reigned 400 years."

Archaeologists date Ku-Bau at circa 2400 BC, and as the only representative of the third dynasty at Kish. Puzur-Sin, the son, however, is estimated by archaeologists at circa 2360-2340 BC, and Ur-Zababa, the grandson at circa 2340 BC. Inconclusive as this is, although suggestive of the celestial beings Venus and the Moon ("Sin"), her son, it would place the barmaid and alcoholic Ku-Bau at 2349 BC.

[\[return to text\]](#)

Note 8 --

There was no Moon until after 2349 BC. So, although there was a Moon at the time of the Isin compilation (after 2017 BC), there was no Moon during the earlier Dynasties. I do not know where the "3 months and 3 1/2 days" comes from. The 3 1/2 days seems like a reference to the reappearance of Jupiter after the fall equinox of 2349 BC (actually 2 and a half days), at which the 3 months could have represented the period before that when the plasma mountain outpouring of Jupiter was missing. This is speculation, although even the *Chilam Balam* reports that Jupiter (Bolon-ti-ku) was not "crying" when the Moon showed up -- in 2349 BC. Similarly, the Babylonian creation myth, the *Enuma Elish*, reports on the disappearance of the garment of Marduk (Jupiter) directly before he wars with Tiamat. This would not have been reported, I feel, unless there was very little time between its disappearance and its recovery. The garment is a skirt, the mountainous outpouring of plasma below Jupiter.

[\[return to text\]](#)

Note 9 --

The Sumerian numbering system was a place-value system like our decimal system, but using column values of powers of 60 (we use powers of 10). But since there was no symbol for empty columns until Babylonian times, it was impossible to differentiate, for example, the meaning of two adjacent wedge marks in cuneiform. It could have a value of 2, or $60 + 1$, or $3600 + 1$.

Cuneiform developed from an earlier pictographic script sometime circa 2500 BC. The numbering system in use at that time also used very similar symbols for units and values of 60.

[\[return to text\]](#)

Note 10 --

Mercury today circles the Sun at the Sun's equator, and its orbit is thus the furthest removed in inclination from the orbit of Earth. It is also on the most eccentric orbit, and with the shortest period. It is difficult to conceive of this planet ever coming anywhere near Earth. But it is certain that initially, after 3067 BC, its orbit was equal to that of Mars. In 686 BC, Mercury made an electric field contact with Earth. It got walloped with a repulsive electric shock, probably on an approach to Earth from the direction of the Sun. This bounced Mercury backward into a much smaller orbit, and at zero degrees inclination to the Sun's equator. The following year Mercury blazed along with Venus.

[\[return to text\]](#)

Note 12 --

There are perhaps other solutions to unraveling the King List of Kish. Wikipedia notes that the second entry, "Kullassina-bel," may actually be a sentence in Akkadian meaning "All of them were lord." Readings like this may apply to the next 9 names.

The names of the next nine kings of Kish (preceding Etana) are all Akkadian words for animals, e.g. Zuqaqip "scorpion" (says Wikipedia). There is an archaeological basis for En-me-barage-si, second to the last king in the list. Of Etana and the following kings many have names which appear in the earliest stories and myths. Archaeologists place the first king on the list at about 2900 BC, on the basis of no evidence except the need for normalcy. I would place the first king of the list at 3067 BC, not at 2900 BC.

It could be suggested that the nine "animal" names are equivalent to the Egyptian pre-dynastic kings with names like Scorpion, Crocodile, and Catfish Chisel. If these are discounted from the list, then, starting with Etana there are only 10 kings left (plus the last king, Aga). This would be fully in expectation of finding a list of ten appearances of Mars over a 300-year period.

[\[return to text\]](#)

Note 13 --

As another example, although this differs from interval counting: After 40 BC Julius Caesar instituted the Julian calendar, which included a provision for a leap day to be added every

four years. The Roman Senate, however, started to add a leap day every three years, a mistake which was not recognized for 36 years. The error came about from the Roman practice of counting years inclusively, so that the first year of a span of four years was the same as the last year of the previous span.

[\[return to text\]](#)

Note 14 --

Matthias Tomczak, in material for a course in "Science, Civilization and Society" at Flinders University in Australia, writes, with respect to the duodecimal counting system:

"A method still in use during the 20th century in the Middle East uses the thumb to point to different parts of each finger [the three finger bones]. Each finger can be used to indicate three numbers, so the four fingers of one hand cover the numbers 1 to 12. This produces the number 12 as an alternative base for a "natural" number system, known as the 'duodecimal system'."

"A logical extension of the duodecimal system is the 'sexagesimal system', which uses the base 60. It uses one hand to count from 1 to 12 and the other hand to indicate the multiples of 12."

If the thumb of the other hand is used to point first to the palm and then to the tips of fingers to tally the counts of 12s made by the other hand, then a total of 60 can be counted. Tomczak notes that this system, or something like it, is still used at stock exchanges.

The duodecimal counting system can also be derived from a method of counting which imagines each finger of a hand as falling in the space between objects to be counted. A single object is not counted. One finger represents two objects, two fingers counts three objects, etc. A dozen is represented by two hands.

A perusal of Maya glyphs immediately turned up the figure above, where a closed fist with **one extended finger** stands for the cardinal number "two" (Website of John Montgomery). I doubt if there will be others representing "three," "four," etc. An image of a thumb is used in some glyphs to represent the number one.

We teach our children the one-to-one correspondence of fingers and objects, and it is so ingrained from an early age that most of us cannot imagine any other method of tallying objects. Ask any two-year old how old she is and she will hold up two fingers. But at her age it is a symbol, not an enumeration. I have had three-year olds disagree with me when I held

up three fingers to denote their age because I included my thumb -- they were not the correct fingers.

Still in use in Pakistan (one of my neighbors tells me) is an almost identical method of counting to 16 on one hand, using the tip of each finger and the joints -- thus 4 counts per finger. This leads to a count of 32 on two hands. It is possible that the sets of 32 stones set up at Western European barrows represents such a counting base (like our base ten) or that it just meant "a lot."

The same can be derived by counting the tips of four fingers with the thumb, and then the base, for a total of 8. The counts of 8s can be tracked with the other hand in fingers: 4 fingers is a count of 32.

Note 15 --

I have earlier suggested that both the axe (or torch) in the head of Mars and the mirror on his forehead could easily date to the period of 800 to 685 BC. The axe in his head probably represents the lightning strike by Venus, which could be placed in 776 BC. The mirror, often depicted as a smoking mirror or a mirror inset with a torch, clearly is the northern ocean (or the remnant of the included deeper ocean, Deuteronilus) steaming water vapor into space. This would account for some of the strange Mesoamerican depictions of Mars. It seems likely that the sublimation of the last ocean of Mars continued into the current era.

Note 16 --

A reasonable attempt was published by Raúl Erlando López in 1998. López assumes a misreading as sexagesimal of figures originally listed in decimal notation. The assumption by López is that the list of Sumer is derived from the book of Genesis, or a common source, although this does not account for the long lives of the patriarchs. He writes:

"The initial section deals with kings before the flood and is significantly different from the rest. When the kingdom durations of the antediluvian section are expressed in an early sexagesimal numerical system, all durations except two are expressed as multiples of 60^2 . A simple tally of the ciphers used yields six 10×60^2 signs, six 60^2 signs and six 60 signs."

"The lives of the biblical patriarchs, however, have a precision of one year. If Adam and Noah are not included (as in the King List), and the lives of the patriarchs are similarly rounded to two digits, the sum of the lives has six 10^3 signs, six 10^2 signs and six 10 signs. In addition, if the number representing the sum of the ages was wrongly assumed as having been written in the sexagesimal system, the two totals become numerically equivalent."

-- Raúl Erlando López, "The antediluvian patriarchs and the Sumerian King List" *CEN Tech. J.* (1998)

Note 17 --

Rome recounts a similar history of seven kings -- eight, if Aeneus is counted. But the Roman historians then list their reign lengths at about 35 years. Wikipedia reports:

"This traditional account of Roman history, which has come down to us through Livy, Plutarch, Dionysius of Halicarnassus and others, is that in Rome's first centuries, it was ruled by a succession of seven kings [starting with Romulus]. The traditional chronology, as codified by Varro, allots 243 years for their reigns, an average of almost 35 years, which, since the work of Barthold Georg Niebuhr, has been generally discounted by modern scholarship."

"The Gauls destroyed Rome's historical records when they sacked the city after the Battle of the Allia in 390 BC (Varronian, according to Polybius the battle occurred in 387/6), and what was left was eventually lost to time or theft. With no contemporary records of the kingdom existing, all accounts of the kings must be carefully questioned. The list of kings is also of dubious historical value, though the last-named kings [two Etruscan names] may be historical figures. It is believed by some historians (again, this is disputed) that Rome was under the influence of the Etruscans for about a century."
[\[return to text\]](#)

Note 18 --

Ussher lists Abraham as born 352 years "after the flood"; Josephus has Abraham born 292 years after the flood. This last figure also seems to recapitulate the 300-year span of kings at Kish, neglecting the initial 80-year period after the flood when there were no kings. But I think that Abraham should be identified with Jupiter rather than Mars.

These calculations involve playing along with the inadvertent errors promulgated by the editors of the Bible in making *their* analysis.

Note 20 --

Dates for Peruvian pyramids are from Carbon-14 dates of baskets left behind with the fill material of rocks and pebbles. At Caral in Peru dirt pyramids are dated to 2627 BC. (San Marcos University, Peru; *CS Monitor*, Jan 3, 2002.) Caral is the oldest of some 25 sites in the Norte Chico region of Peru, where other pyramids were started after 2556 BC (Northern Illinois University, Dec 23, 2004; the date was listed as "4560 years ago.")

Occupancy of these sites dates to 3100 BC. Thus the pyramids start 400 to 500 years after the local people first start using the sites. This is no different from Egypt and Mesopotamia. In

all cases construction of pyramids does not happen before 2700 BC.

[\[return to text\]](#)

Note 21 --

Senmut is dated to about 940 BC in the revised chronology of Velikovsky.

[Image: A portion of the tomb of Senmut, circa 1500 BC, Thebes. Construction halted in 1493 BC. After Wikipedia, under GNU General Public License.]

For an analysis of the images see Ove Von Spaeth "Dating The Oldest Egyptian Star Map" *Centaurus* V42 (2000). Von Spaeth notes that the rock cut tomb was abandoned during construction in 1493 BC (what a coincidence!). The central portion depicts the circumpolar constellations. The circles represent 12 calendar months of 24 divisions each, for a total of 288 days -- 15 days longer than my estimate of 273 days for the length of the year after 2193 BC.

There are other possibilities. Redating to 940 BC is one option. Additionally, since calendars are very conservative, it is possible that the 24-day months are a holdover of an earlier calendar (when there also were 10 months, not 12). It would not be untypical for a religious calendar to retain an older outdated form. A portion of the decans and planets are shown on the bottom. Von Spaeth suggests the planets show a conjunction of all the planets (except

Mars) in 1534 BC (under uniformitarian conditions). Later tombs duplicate this arrangement when the conjunction is repeated (with Mars). The conjunction of all the planets marks the start of a "Great Year," although this is a notion dating to the 7th century BC.

"The main theories of astronomy are as
remote from experience as to be spooky."
-- Alfred de Grazia *The Divine Succession* (1983)

Celestial Mechanics

This appendix presents the celestial mechanics I have used as background to the narrative of this text for the events of 3147 BC and after. I will use the year 3147 BC for the end of the "Era of the Gods" throughout. This appendix presents likely orbits of the planets, which do not deviate from what would be expected under the influences of gravitational and occasional electric forces.

One reason for this discussion is to counter interpretations like, "Mars then left its regular position and almost collided with the earth in about 700 BC," as Stephen Jay Gould wrote in *Ever since Darwin* (1977). Planets do not leave their orbits.

But orbits change over time in relation to each other, enough to have caused interference in the remote past. It is unfortunate that Velikovsky titled his 1950 book *Worlds in Collision*, when there were no collisions, and could not be. The electric interaction between "colliding" planets happened at distances of tens of millions of miles, except in 800 to 650 BC, when Mars indeed came very "close."

Scavenging Planets

I have in previous text maintained that Saturn would have come in from the far reaches of

space with a large positive charge, larger than any of the planets of the Solar System. The Solar System planets would thus be at a negative potential with respect to Saturn.

First, this explains how in meeting up with Jupiter in 3147 BC, both the Saturnian planets and Jupiter were cast into orbits far removed from the Sun. I'll detail the likely geometry of this further below.

Second, it explains how Saturn could have reduced its orbital period from 27,000,000 years to what I estimate to be something on the order of 4000 years, and subsequently reduced it to a value close to a year. In both of these cases Saturn would have been pulled into the Solar System on meeting up with Jupiter on one of its excursions into the inner region of the Solar System. Saturn became a Solar System planet because of the attractive electric field forces between Jupiter and Saturn.

At an orbital period of 4000 years (just as an example) the radius of the orbit would still be an astounding 252 AU. This means Saturn would exit the Solar System on its orbit. A measure of 4000 years for the return of Saturn can be deduced from Book 11 of the *Chilam Balam* -- exceedingly long periods of no sightings of Saturn between appearances, "when there was infinite night." When Saturn made an appearance, it would have been seen for perhaps a decade before disappearing again, because within the Solar System Saturn would travel at the expected speed of a comet or any other celestial body.

It would normally be expected that Saturn and its companion planets would show in the sky as a giant meteor. But there is no recognition of a plasmasphere tail among any of the millions of Venus Figurines. Comets at times do not show a tail, and only infrequently show a bow shock. Comet Holmes in 2007 had only a slight, hazy, and short tail. Comet Holmes was also described as looking like a "bright yellow star." The reader might recollect a description of figurines from the Gravettian period of the Upper Paleolithic as being carved in buff or amber colored limestone (reflecting the buff color of the Absu).

That means that during the Upper Paleolithic, during the time of Cro-Magnon, Saturn was only seen periodically. The long periods between appearances accounts for the fact that the Venus Figurines apparently disappear from the archaeological record for periods of up to 10,000 years (4000 years on average). Only after about 10,900 BC are we certain that the period of Saturn had been reduced to something on the order of a year. This marks the start of the Younger Dryas, and marks the time when Earth was scavenged also. The change in the orbital period of Saturn may have happened earlier, at the beginning of the Neolithic, although nothing of the Venus Figurines show up before the middle of the Neolithic, circa 6000 BC.

Third, it is the greater positive charge on Saturn which accounts for how other Solar System planets could have been scavenged over a period of the last ten million years. Each of the smaller Solar System planets was drawn closer to Saturn, and each found a subpolar or suprapolar location.

At first sight, it would appear that a magnetic connection sustained the grouping of the five-planet stack, except that Mars has no magnetic field. This is also not a case for suggesting that, with the lack of a magnetic field, Mars might have wandered from its position directly below Mercury. But, except for the periodic lowering of Mars, we have no real record of wandering (However, Talbott does, in the imagery presented in *The Saturn Myth*). What is much more certain is that Mercury wandered left and right, which shows up in the fan- or shell-shapes of the plasma streams impinging on Mercury (as detailed by Talbott).

It is not the magnetic field that aligned the planets. They are aligned because that is how they are normally oriented in the space of the Solar System -- with north as up and south as down, and with a north-south magnetic dipole presented the same way. Jupiter, however, is the exception; its magnetic north pole is at its geographic south pole. Magnetic forces are not powerful enough to move planets around.

It thus might be a coincidence that we find the planets in the stack "as if" they are held together by magnetic forces. With all the south and north poles aligned -- even with Uranus on its side so that its south magnetic pole is above the north magnetic pole of Neptune.

They also violate the concept of magnetic attraction in that they remain separated from each other. We have to suggest that most likely the planets stayed separated because of their electric fields, but this also is negated. The obvious passage of plasma from Saturn to the other planets reveals that Saturn and its solar planets were not at the same charge level.

So what kept the planets apart? Van Flandern would say that the captured planets were just satellites traveling with Saturn. They would remain on an orbit around the Sun parallel to their primary. Apparently what might happen at close range is entirely different from what we would expect planets to experience at large separation distances. We can find other excuses: the magnetospheres of planets are very complex, with space charge sheaths and currents crossing at different locations. And the flow of plasma, in that it is an electric current, created additional local magnetic fields.

The Asteroid Belt

The asteroid belt of the Solar System is strewn end to end with rocks and grains of silicate dust. In the 1970's it was estimated that there might be 100,000 asteroids. Today 300,000 have been detected and plotted, and the estimate for additional smaller asteroids ranges into the millions.

A plot of locations and plots of orbital inclinations and orbital eccentricities of the asteroids reveals that these objects are on wildly chaotic orbits, and have been subjected repeatedly to unpredictable gravitational and electric forces as Saturn passed through the belt (and much later followed by Jupiter and the Titans after 3147 BC). The dispersion of the asteroids is probably mainly due to gravitational disturbances and electric repulsion. The ubiquitous cratering, however, is due to electric arcing.

The distribution of asteroids is mainly in the region from 2 to 3.5 AU, between the planets Mars at 1.5 AU and Jupiter at 5.2 AU (with more among the inner planets and at 40 to 50 AU). The eccentricity of the orbits and the great variety of orbital inclinations suggest additionally that the asteroids represent a very old history of cataclysmic interactions. The distinct groups of iron meteorites and 3 groups of distinct stony meteorites (distinct by chemical and crystalline makeup) would seem to constitute four separate rocky or dead planets which could have inhabited the space between 2 and 3 AU, but which were blown apart by Saturn entering the Solar System in the remote past, after a long absence, and more frequently in the last ten million years.

These outer planets would have been the first objects encountered by Saturn on entering the Solar System and the prime target for interplanetary thunderbolts of huge proportions. Jupiter, Neptune, and Uranus could absorb such lightning strokes, for they have gas and liquid envelopes. A rocky planet would not withstand a bolt -- the rush of electron to the surface would break the bonds of the silicates and blow the planet to smithereens, especially if it was similar in size to Mars or the Moon.

... source of the Asteroid Belt

In the 1960s and 1970s, on the basis that the asteroid belt represents the remnants of the dust which "coagulated" to form the Sun and planets, it was assumed that some objects (asteroids or comets) would be traveling on hyperbolic trajectories, representing objects which either had recently been subjected to "collisions" with other objects, or were entering the Solar System from outside of the region beyond any of the planets. On an "open hyperbolic trajectory" such objects would never return after once entering the inner reaches of the Solar System. If this was how stars and planets were created, then this should still be happening.

But no hyperbolic orbits have ever been found. All trajectories are closed elliptical orbits -- paths which bring the meteor or asteroid back. This suggests that the asteroids are not remnants of "planet formation dust," and that the asteroids are local residents (they did not enter from interstellar space). Additionally it indicates that the interactions which led to their wildly elliptical and greatly inclined orbits were local and had culminated a long time ago, rather than continuing to today.

I would suggest an alternate theory of planetary breakup and dispersal of the material over time. An estimate of the depletion of the asteroid belt could be made on the basis of the repeated passages of Saturn through the belt. If on a first breakup of a planet only 15 percent remained on closed orbits, and then, with each of 40 passages of Saturn (20 in each direction) through the broken rocks perhaps another 10 percent was lost each time -- in effect ejected from the Solar System -- then what would remain would be only 0.2 percent of the original mass (0.002).

$$0.15 \times 0.9^{40} = .002$$

Today it is estimated that all the asteroids together make up a mass of a sphere less than half the diameter of the Moon, and thus 1/8th its mass. The mass of the moon is:

$$7.35 \times 10^{22} \text{ kg.}$$

One eighth of this is about:

$$1 \times 10^{22} \text{ kg.}$$

If today the remnants add up to only $1 \times 10^{22} \text{ kg}$, then the original planets could have amounted to a half dozen moon-sized to mars-sized bodies -- totaling $500 \times 10^{22} \text{ kg}$.

[\[note 1\]](#)

- The Earth has a mass of $600 \times 10^{22} \text{ kg}$.
- Mars has a mass of $64.1 \times 10^{22} \text{ kg}$.

- The Moon is 7.3×10^{22} kg.

... gaps in the Asteroid Belt

What is left today is an array of objects widely dispersed, mostly located in a region spanning some 200 million to 350 million miles (320 million to 565 million km) from the Sun, but all on stable orbits. One element of this stability is the existence of some ten distinct gaps where no asteroids (or few) are found. All these gaps are at locations where the orbital period is a fraction of Jupiter's period today, 2:1, 3:1, etc., up to 5:1 (and a few odd ones).

It is assumed that the gaps were created as asteroids at the gap locations passed the radial location of Jupiter (objects closer to the Sun travel faster than objects further away) and were thus subjected repeatedly by the gravitational tug of Jupiter with each passage past the location of Jupiter, even though this amounts to only a fraction of a percent of the gravitational effect of the Sun.

[Image: "Histogram of the semi-major axis of asteroid objects; gaps in the belt are marked on the abscissa." (Data: <ftp://lowell.edu/pub/elgb/astorb.html>. Plotted at case.edu/sjr16/; additional graphics added.)]

This would certainly be true if Jupiter had been at its present location for billions of years. But this would not be true, or would represent only an incomplete process, if, as I have maintained, Jupiter had only arrived at its present location since about 2200 BC. Yet many of the gaps, especially those far from Jupiter's current location are well established, although admittedly many gaps represent only approximations to the current orbital period of Jupiter (some of which is due to the difficulty in making observations). [\[note 2\]](#)

If Jupiter had been at its present location for over 4 billion years, then the gaps in the asteroid belt, even though resulting from gravitational tugging amounting to a fraction of a percent of

what an asteroid experiences from the Sun, would have to be more clearly defined than they are now, especially closer to the current location of Jupiter. Over the course of 4 billion years the belt would have segregated into very clearly defined rings and the gaps closest to Jupiter would have been the most clearly defined. Astronomers have wondered why the asteroid belts are not uniformly segregated into rings. And there have been questions on why inward gaps (nearer to the Sun) are better defined.

[Image: Kirkwood gaps in the asteroid belt; detail.]

In fact, we might expect that all of the material would have dispersed by now. Four billion years is a very long time. Asteroids at the 2:1 resonance location would have passed Jupiter 8 billion times; asteroids at the 5:1 resonance location would have passed Jupiter 20 billion times.

If Jupiter actually had spent all of its time, since the earliest creation of the asteroids, at a much closer distance to the Sun, rather than 5.2 AU, could the same gaps be accounted for? In fact, if Jupiter were located at 0.7 AU the same gaps would result from resonance with the period of an inner location, 1:4, 1:5, etc., up to 1:10 (and a few odd ones).

This is not entirely a coincidence, since any inner location of an orbit of Jupiter would also establish resonances throughout the asteroid belt. I checked for resonances at other distances, but 0.7 AU looks most likely. [\[note 3\]](#)

From my perspective, this answers the question of how close Jupiter was to the Sun before 3147 BC. I had earlier suggested, "at one or two AU." Now Jupiter can be placed at 0.7 AU with fair certainty and probably on a fairly circular orbit. (0.9 AU is another good possibility.) Saturn and its planets would have to be on an elliptical orbit which came closer to the Sun at perihelion and extended past 0.7 AU in its aphelion. That is also the only way

Jupiter and Saturn could have "collided" in 3147 BC.

Resonance of Asteroid belt gaps for current and previous location of Jupiter				
approximate asteroid gap [AU]	Jupiter at 5.19 AU		Jupiter at 0.7 AU	
	value	resonance	value	resonance
1.78	1:0.201	5:1	1:4.05	1:4
1.91	1:0.223	9:2	1:4.51	2:9
2.06	1:0.250	4:1	1:5.05	1:5
2.26	1:0.287	7:2	1:5.80	1:6
2.50	1:0.334	3:1	1:6.75	1:7
2.70	1:0.375	8:3	1:7.56	3:4
2.82	1:0.401	5:2	1:8.09	1:8
2.96	1:0.431	7:3	1:8.70	?
3.03	1:0.446	9:4	1:9.01	1:9
3.28	1:0.502	2:1	1:10.14	1:10

If Saturn were on an eccentric orbit with a period of 225 days as experienced by its companion Earth (as suggested in Appendix A, "Chronology") then the average orbit of Saturn would have to be 0.72 AU. Assuming an eccentricity of 0.25, perihelion would have been at 0.54 AU and aphelion at 0.9 AU. This would certainly not fry the Earth to a crisp. It would keep the northern hemisphere at a reasonable climate (although warm).

An eccentricity of 0.25 is large compared to that of the planets today, but not unrealistic. Mercury today has an eccentricity of 0.20, and Mars still has an eccentricity of nearly 0.10. In 670 BC Venus had an eccentricity of 0.15. One reason for selecting an eccentricity of 0.25, is to keep the Earth at least a reasonable distance from the Sun. A perihelion of 0.54 AU is halfway between the current orbits of Venus and Mercury.

3147 BC, the End of Paradise

In 3147 BC everything came apart. I imagine a scenario like the following, although other arrangements could as well have been the cause.

We begin with Saturn and the planets traveling with Saturn, while on their elliptical orbit. Jupiter caught up, traveling faster on an inner orbit. This corresponds also with the imagery from antiquity: that the city of the Gods -- Saturn and its satellites standing above Earth -- was destroyed by the bull of heaven. Back lighted by the Sun, and traveling on an orbit inclined above Earth, the bull's Aurochs-like horns were seen.

[Image: 3147 BC, an electric field interaction between Jupiter and the Saturnian planets. Illustration by J. Cook.]

I would presume that the interaction of 3147 BC was based on something of this sort, or a close parallel. When the plasmaspheres of Jupiter and the Saturnian planets made contact they were subjected to electric forces of unbelievable magnitude, for the distances separating them was relatively small -- my estimate is 6 to 14 million miles (10 to 23 million km).

Although it is possible that the plasmaspheres of the two planets made contact at a maximum separation (17 million miles, 27 million km), from what scant information we have of the results, it seems much more likely that the contact was made at relatively close quarters.

I was not happy with my earlier attempts at moving the four large planets out to huge distances with repulsive forces, as would normally have happened between electrically negative planets. Then I realized that an interaction with Saturn would have had to involve an attractive force. This is accounted for by realizing that Saturn came from outside the Solar System, and would have had a very considerable positive charge, larger than that any of the Solar System planets.

Having Saturn much more positive than any of the other planets makes Jupiter negative with respect to Saturn. This defines an attractive force between the two. This would result in a serious impulse at an angle to the orbital direction. The result would be to place the planets on elliptical orbits which, at the extreme, would have cast them out of the Solar System.

This is how Earth's artificial satellites change from one orbit to another, except that the Earth-satellites receive a second impulse to inject them into a destination orbit. One cannot have a satellite travel endlessly on a spiral away from the Sun. At some point the further advance has to be curbed.

If then Saturn were to meet Jupiter while outside of Jupiter's orbit, Jupiter would have been yanked away from the Sun, assigning it to a far distant location from the Sun. The Saturnian planets would similarly have been yanked backward, onto trajectories at an angle to their

original orbits.

The forward speed is determined by the orbit. Slow speed, far out; high speed, close in. From Kepler's "third law" you can find the speed, or at least the period:

$$(\text{orbital period})^2 = (\text{orbital radius})^3$$

How then, did Jupiter, Saturn, Uranus, and Neptune all stay within the Solar System, although at very distant orbits, and even circularized? It just does not make any sense if we only think in terms of elliptical orbits. The only solution is to suggest a spiral path. This is not discussed in orbital dynamics, since it leads nowhere useful in terms of altering Earth-satellite orbits.

But each of these planets had to pass through the asteroid belt. A suggestion that I can therefore offer is that each of these planets was retarded in passing through the mass of the asteroid belt. Could this be? The mass of the asteroid belt does not amount to much, although each of the outer planets would have been in intimate contact with a considerable portion of the asteroids. It might be that there were many more asteroids at one time. This is not unreasonable, since when the asteroid belt was last disturbed it was at a time when four giant planets made their way through, 5000 years ago. The only other alternative would be to suggest some force which is not in the purview of accepted physics. I'm not about to do that.

Venus and Earth were excluded from the electric forces which moved Jupiter, Saturn, and the Titans. Both Venus and Earth were some considerable distance away from (below) Saturn. A reformed plasmasphere of Saturn most likely resulted in their exclusion.

Tom Van Flandern would suggest, instead of reformed plasmaspheres, that the gravitational sphere of influence decreased with the addition of the nearby mass of Jupiter. Under this concept, too, the Earth and Venus would have been released from their duties as satellites.

Having Jupiter approach Saturn because of an attractive electric field force also clearly delineates the blame. The Palette of Narmer shows the "Bull of Heaven" wrecking the city of the Gods. The *Chilam Balam* is also clear about an immediate contact:

"Then Oxlahun-ti-ku [Saturn] was seized by Bolon-ti-ku [Jupiter]."

"Then [when] Oxlahun-ti-ku [Saturn] was seized, his head was wounded, his face was buffeted, he was spit upon, and he was (thrown) on his back as well."

Obviously, starting with attractive forces, there would have been an immediate charge imbalance, not induced as in all the other situations, and as a result the immediate start of a continuous lightning bolt. That too is what the *Chilam Balam* says.

There was no intermediate agent, as in the plasmoid of Venus in 2349 BC, which was

variously presented as a dragon or an angry goddess. In this case it was Jupiter who was the agent, and clearly identified in Egypt, Mesopotamia, and Mesoamerica. The graphic and verbal descriptions suggest considerable violence. Jupiter was understood as a celestial bull not simply from its looks, but from the apparent impact it had in wrecking the city of the Gods. Jupiter would have looked like an approaching bull with its huge broad-shouldered shape of its lower coma and with a coma as the head (complete with eyes) with horns on top, formed of the chalice-like plumes above the upper magnetic pole.

An estimate of the size of the plasmaspheres of Jupiter and Saturn, of about 40 planet diameters for each, will suggest how close the two planets came to each other. (Jupiter's plasmasphere today extends some 40 to 100 planet radii from the planet's center -- 2.5 to 4.5 million miles, 4 to 7 million km.) This amounts to about 3 million miles for each on average, and thus a total horizontal separation of about 6 million miles (10 million km) minimum.

The other estimate of a separation distance can be had from the Bible and Vedic references to a bright light flooding Earth day and night for seven days -- which Velikovsky thinks preceded the flood, correctly so, but it was the flood of 3147 BC, not Noah's flood. Isaiah, in a prophetic mood, describes a cataclysm to come as:

"the light of the moon shall be as the light of the sun, and the light of the sun shall be sevenfold, as the light of the seven days...."

Ronald Knox, however, translates the last line as, "as if the light of seven days were joined in one." Jan Sammer and Velikovsky point to Vedic sources, possibly more accurate Talmudic sources, and the Sumerian *Epic of Gilgamesh*. (<http://www.varchive.org/eclight.htm>). Genesis 7:4 also makes reference to a seven-day delay before the flood.

Notwithstanding the particular translation by Knox and the illusive quality of some of the other sources, the concept of seven days of a very brilliant light before the flood (the flood of 3147 BC), makes sense.

A model immediately comes to mind: on sensing Saturn and the other two large planets electrically, Jupiter would have started to relocate away from the Sun, mostly in the forward direction of its travels. The very act of relocating would cause it to start shedding charge to match the changed electric condition of being at a different distance from the Sun. Jupiter would have lit up in glow mode. The coma that developed was three times the diameter of the Sun (it still is today, but in dark mode). As we know from comets, a glow mode coma, even for a very small object, can light up the night skies as brightly as the Sun.

Jupiter would have relocated and would have remained brilliant far past the original location of Saturn (as we know). But for humans it was over as soon as Earth was released from below Saturn. That brought the flood. So to this point in time we can count seven days of travel for Jupiter. Or perhaps less, since the flood might have taken a few days to arrive from

the south.

If, as I suggested earlier, Jupiter were located at 0.7 AU, then its orbit would be $\pi * 2 * 0.7 * \text{AU} = 409,000,000 \text{ miles (659,000,000 km)}$, and its year would be 214 days (from $365.24 * \sqrt{.7^3} = 213.9$). The orbital speed would thus be 1,920,187 miles per day (3,090,000 km per day). Assuming a travel velocity no greater than Jupiter's forward orbital speed, in seven days it could have traveled about 14,000,000 miles. The initial attractive force, which changed the direction of travel to some value above a tangent to the original orbit, would have to overcome Jupiter's forward momentum, and would not likely last all that long, and certainly not seven days. As the plasmaspheres reformed, the electric fields of the planets would again isolate them from each other.

Is the interaction distance reasonable? We can't argue with the time it took to yank Saturn away from Earth. First, 14,000,000 miles (22,500,000 km) is twice what I had suggested earlier in the text above as the separation based only on estimates of the sizes of the plasmaspheres of the two planets.

Second, I will assume that both Jupiter and the Saturnian planets would have been subjected to an initial impulse force which probably lasted no longer than minutes.

Third, what we have here is markedly different from the descriptions of other electric field interactions, in that there was no restraining force -- something that in all other cases kept planets from continuing onward after the initial repulsive shock. The restraining effect for a repulsive electric force was always provided by the induced charge, which would provide an attractive force to counter the initial repulsion.

So, in this case, Jupiter, Saturn, Neptune, and Uranus were destined to travel forever outward from the Solar System. I would suggest that the eventual restraining effect was provided by the material of the asteroid belt.

Earth stayed behind when Saturn started to move away. At the end of the flood Jupiter was seen with a crescent of sunlight on the planet, seen through its coma, and placed as Noah's ship on top of a green mountain. It was thus located outside of the orbit of Earth. There is more than one image of Jupiter like this as seen by humans and reported on.

Earth was loosened from the grip of Saturn, for the presence of a planet with more than three times the mass of Saturn would have reduced the gravitational sphere of influence of Saturn (as defined by Van Flandern). Not only was Earth outside of Saturn's new sphere of influence, but with Saturn moving away, the Earth's orbital speed no longer matched. Mercury and Mars remained with Saturn.

The Earth at this time was already on a new path about the Sun, and was experiencing the worldwide flood. Jupiter might have been seen in the daytime, but certainly not for long. As the flood came to an end, in a week or two, Jupiter had already relocated to the south skies,

and was receding from Earth and from the Sun. The light of seven days came to an end as Earth moved past Jupiter's lower plasma plume -- its mountain.

This type of "collision" would have had a very low probability of ever happening, for although Jupiter and Saturn were on nearly the same average orbit, they had likely fallen into a synchronous relationship which would vary only slowly. The variation in the relationship of the orbits of Jupiter and Saturn would probably be on cycles spanning tens of thousands of years. But at some point in time there was going to be a close call, where the distance between Jupiter and Saturn would become critical. That happened in 3147 BC.

All four of the large planets relocated to a distance from the Sun approximately inversely proportional to their mass, with the exception of Uranus. Nearly the same electric field force was experienced by all the planets (as a diagram of relative positions will indicate), and thus the increase of the orbital distance from the Sun would have been proportional to the inverse of their mass. The exception is Uranus, which should have been relocated to an orbit beyond Neptune, but was not. Uranus's orbit was relocated to an orbit nearer to the Sun than the orbit of Neptune. I'm not sure what might explain that, except perhaps the direction in which the stack of the Saturnian planets was leaning.

If the stack leaned away from the approaching direction of Jupiter, then Uranus would be the most distant from Jupiter when all three planets received their initial attractive shocks, and Uranus would have received a lesser shock (which falls off with the distance). I am assuming here that the force of the electric impulse would have been proportional to the coulomb charge of the planets, and that these in turn would have been a function of their mass, or at least their surface area. This is not quite sufficient to explain the much larger orbit of Neptune -- an additional 1000 million miles beyond Uranus at 1,700 million miles (2,700 million km).

Considering the enormous charge carried by the giant planets, it will become obvious that reforming of the enclosing plasmasphere for the large planets would lock out the smaller planets, so that the smaller planets, enclosed in their own newly configured plasmaspheres, never experienced the electric field force of Jupiter or Saturn and the Titans. Otherwise Earth would have been tossed out of the Solar System.

The tiny planet Earth, the furthest from the Saturnian group, remained on an inner orbit. Venus was torn away (escaped) somehow from Saturn and Neptune. Venus may have been excluded simply because Venus was on an orbit far above and outside of the rings of Saturn, and possibly not located between Jupiter and Neptune at the moment the plasmaspheres touched. From "reports" from Greece, Venus seems to have rounded the globe of Jupiter ("his skull"), still located on the night side of Earth, before heading into an orbit around the Sun with a period nearly identical to the orbit of Earth (as would be expected).

Mercury and Mars were carried along by Saturn as if they were satellites, which in effect they were. Mars and Mercury remained with Saturn and were not released until some 80

years later, when Saturn entered the asteroid belt and reconfigured its plasmasphere, making it much smaller. [\[note 4\]](#)

Axial Inclination of Earth

Earth would relocate immediately to a new elliptical orbit which would have the Sun as one of its centers (nodal points). The start of this orbit -- the location of the release -- would constitute the aphelion of the orbit (on the seasonal equivalent day of May 28th, according to the Maya "blowgunner" pot) and is the location Earth would return to during its circuit around the Sun until the orbit changed again in 2349 BC.

Today the aphelion falls in early July, somewhere around July 4th to July 6th (the dates vary on our calendar). A change of 10 or 15 degrees in the location of the aphelion (as happened in 685 BC) was suggested by Rose and Vaughan in 1994. That is the 15 day advance in the equinox, as I have determined also, counting a degree as very close to a day.

In terms of today's calendar, the aphelion moved a total of 36 days: 3 in May, 30 in June, and 5 in July. On the basis of the changes in 685 BC, the original aphelion in 686 BC can be placed at June 20th, on today's calendar (15 days earlier). This is the solstice, to within a day (it varies with leap year adjustments). The remaining difference of 23 days (May 28th to June 20th, inclusive) represents changes in the number of days in the year. Changes in the days of the year, using $225/365$ as a factor, would account for 14.8 days. That still leaves 8 days unaccounted for.

This is likely accounted for from a change in the axial inclination -- this would account for a sudden advancing or retarding of the calendar. Thus in 685 BC, when the inclination went from 30 degrees to 23.5 degrees, the solstice advanced 15 days in the calendar. This event is previously established, and already taken into account (above).

On the other hand, the eight days might represent the completion of the removal of Saturn, but cast in terms of the last of the World Flood. The 2000 to 3000 foot deep deposits of fossils at the Siwalik hills (the foothills to the Himalayas), interleaved with layers of mud, looks like the work of repeated tsunamis of astounding magnitude.

[Image: "Done by Hun-Ahau; on 1-Ahau 3-Kankin he entered the sky, Itzam-Yeh." After David Freidel and Linda Schele "Maya Cosmos" (1993).]

The seasonal date of May 28th is how both the classical era Maya as well as archaeologists calculated from an unadjusted Long Count. The year of 3148 BC might be a coincidence (although I doubt that). What is important is that 1-Ahau 3-Kankin can be translated to a sunset location of 23 degrees above west if we assume this was determined for a latitude of 19 degrees north which is sort of the midpoint of Maya occupation.

The question then becomes, what would be the latitude for a solstice sunset location of 23 degrees north of west? Today's solstice of June 21 can safely be used to calculate this, but it would have to be set for a different axial inclination of the Earth. Elsewhere I have determined that a value of 25.2 degrees for an earlier axial inclination would be reasonable, after the Australian astronomer G.F. Dodwell.

The axial inclination of 25.2, however, is Dodwell's weakest data point, and it would be acceptable to modify this somewhat. Dodwell assumes that the Earth was jolted in 2550 BC or so, and corrected itself over time. His measure was taken from a pylon at Karnac, built after 2549 BC. My take is that until 1492 BC the initial inclination of the Earth's axis remained the same.

I am suggesting 25.0 degrees rather than 25.2 degrees. At 25.0 degrees, the solstitial sunset would be 23 degrees north of west for a latitude of 1 degree north. It could be south also; but at any rate it is a location near the equator. This could be inland Venezuela as the earlier location for the Olmecs (as I have suggested), or Columbia or Ecuador. [\[note 5\]](#)

Outer Planet Orbits

The current inclinations of the orbits of Jupiter and the other outer planets, in degrees above or below the equator of the Sun, should reflect their interaction in 3147 BC. The current inclinations are the retained history of the starting point of the "collision" of 3147 BC at 0.70 AU from the Sun. This is a very simple and obvious consideration which has not been

broached by any researcher in 60 years.

There would be no reason for the inclination of the orbits to change, although it remains to be suggested that the orbits might "flatten" over a long period of time under the gravitational influence of the other planets. But the angle of the eventual orbit would mainly have been determined by the angle each of the larger planets made with the equatorial of the Sun at the location where they were all coincident in 3147 BC. We should thus be able to get a glimpse of the vertical separation distances between the larger (outer) planets in 3147 BC.

Although I have confidence in determining the vertical separation of the outer planets, I have somewhat less confidence that we could extract relevant information about the inner planets, for they have been released from the grip of Saturn at different times and would thus have established their new orbits (with the Sun at one of the centers of the ellipses of the new orbits) at an unknown location other than 0.70 AU.

object	inclination of orbit to ecliptic [degrees]	inclination of orbit to Sun's equator [degrees]	vertical separation of adjacent planets [million miles] as shown
Uranus	0.77	6.23	1.95 (above Saturn)
Jupiter	1.31	5.67	1.34 (above Saturn)
Neptune	1.77	5.23	0.82 (above Saturn)
Saturn	2.49	4.51	-1.34 (below Jupiter)

The chart above shows the vertical distances between the four large planets in 3147 BC. The vertical separation between planets assumes all were located at 0.7 AU from the Sun. The inner planets will be considered separately, below. [\[note 6\]](#)

Predictably, Uranus is at a considerable distance above Saturn, nearly two million miles. Saturn in turn is below the "level" of Jupiter, by over a million miles. Thus Earth would have been even lower and Jupiter would initially have been seen from Earth from a low angle. As described in the various flood legends, the crescent of the Sun's light would have been seen on the lower portion of Jupiter, understood as a "ship" moored to a "mountain" of plasma discharging from the south pole of Jupiter and green.

Neptune, which definitely is a Saturnian planet, can be fit into this configuration. We do not know anything of this planet from mythology (except for references in the Quiche *Popol Vuh*). The name for the planet was selected in AD 1846 to match classical mythology as being one of the Titans banished by Zeus (Jupiter), as related by Hesiod. (Uranus was similarly named, but the planet certainly is not the Uranus "Father Sky" who was the father of Kronos, Saturn.)

Although it might turn out that Neptune could be associated with one of the Gods or Goddesses of antiquity, it is unlikely that Neptune was ever seen (although recounted by the *Popol Vuh*), since it would have been directly above Saturn and certainly was close enough,

0.8 million miles (1.3 million km). Saturn is twice the diameter of Neptune. Saturn and its rings would have easily obscured Neptune.

The reason for considering the possibility that Neptune had hovered above Saturn before 3147 BC is that Neptune is today found in the extreme reaches of space, in fact, at 32 AU. Additionally, both in the earlier Gravettian period of the Upper Paleolithic (28,000 to 24,000 ya) and again after about 5600 BC, the figurines display distinct breasts above the large belly and rump. With Uranus forming the head, and Saturn the belly or body, the location of an additional planet directly above Saturn would be required to form the breasts, probably as an outline of its equatorial toroidal plasma belt. Neptune is larger than Uranus.

The most convincing evidence comes from the Magdalenian period of the Upper Paleolithic, 17,000 to 14,000 years ago, when the Venus Figurines, from a period 10,000 years earlier, become strangely elongated and hardly realistic looking. Elsewhere I have postulated that at about this time Earth had visually risen in its orbital latitude (or Saturn was on a part of its orbit more inclined to the Sun), so that the figure of the Saturnian planets was no longer foreshortened into the typically squat Venus Figurines of the Aurignacian and Gravettian periods of 30,000 to 24,000 year ago. Rather than dismiss the sculptors of this era as incompetent, as many archaeologists do, I suggest that we are being presented with a realistic depiction from a point of view where the orbit of Earth is at nearly the same level as the Saturnian planets. Without too much effort the sculptures reveal four or five separate globes connected with an enclosing plasma. The sculptures are being forced to appear as an image of a woman, because that had been the long-standing tradition.

... outer planet spin rates

I have assumed (earlier) that the electric and gravitational interaction in 3147 BC slowed the travel of each of the large planets to a value which would correspond to the new (slower) orbital speed of each of these planets at their eventual location far from the Sun.

Of course we have to ask, if both Jupiter and Saturn slowed to a orbital speed which they would have at their remote locations, what happened to the kinetic energy and rotational momentum?

The repulsive electric interaction, which altered the forward speed of the planets, was short lived. Likewise the electric arcing which was involved in the near collision must have been enormous, but these simply cannot account for the energy exchanges which were involved. Plasma exchanges, even in arc mode, are always constrained by time and are self-limiting.

What then happened to the kinetic energy and the potential energy in the collision of 3147 BC? The simplest answer might be to suggest that the orbital rotational momentum which was lost by each of the planets was translated to spin rotational momentum. In fact, both Jupiter and Saturn spin at inordinately high rates for their size (9 and 10 hours).

What I have suggested earlier is that Saturn revolved at about 24 hours before 3147 BC, so that from Earth, below its south pole, Saturn would have stood still. This suggestion could be extended to the other outer planets also, that is, that each of them in relocating to a larger orbit (which reduced orbital rotational momentum) increased their spin rate (which increased the rotational momentum of spin).

On strictly mechanical terms, the conservation of rotational momentum will not allow this unless the planet somehow gained mass, increased in size, or a force was applied. That force was due to an electric field. I suspect, therefore, that, before the collision, Jupiter, Saturn, Neptune, and Uranus, rotated about their individual axes at a lower rate than they do today.

[\[note 7\]](#)

New Inner Planet Orbits

The inner planets Venus and Earth, released from the gravitational grip of Saturn, immediately started on new orbits with the Sun as one of the centers. The orbital inclinations shown in the chart below are calculated as before. It shows that Mercury and Venus started from above Saturn. Mars and Earth, however, started from below Saturn. Earth started from 2.8 million miles (4.5 million km) below Saturn. Mars started from 730 thousand miles (1,175 thousand km) below Saturn. Both as expected. But see the caveat below.

object	inclination of orbit to the ecliptic [degrees]	inclination of orbit to Sun's equator [degrees]	vertical separation from Saturn [million miles]
Mercury	7.0	0.00	-5.13 (sb below)
Venus	3.4	3.60	-1.03 (above)
Saturn	2.49	4.51	---
Mars	1.85	5.15	0.73 (below) **
Earth	0.0	7.00	2.83 (below)

What the chart shows is that Venus would have had a location well above Saturn, and in fact close to the inclination of Jupiter (as also confirmed by "mythology"). The data for Mercury is suspect. It looks to be very far above Saturn, although I have suggested that Mercury was located directly below Saturn. That means the compressive shock between Earth and Mercury in 686 BC not only radically changed the orbit of Mercury, but must have changed the orbital inclination to the equator of the Sun as well. [\[note 8\]](#)

The terms "above" and "below," in the chart above, were selected on the basis of today's angular separation. The location of Mercury is incorrect; it should have been below Saturn. Details for the Earth's contact with Mercury are shown further below.

The seven-degree angle which the Earth's orbit has (today) to the Sun's equator, the largest of any planet, speaks to the fact that Earth was furthest removed from the vertical location of the other planets. Were we lucky?

The distance of 2,830,000 miles (4,557,000 km), shown in the chart above, between Earth and Saturn differs significantly from my first estimate (not shown in these texts) which placed Earth a half million miles below Saturn, so that the disk of Saturn would subtend ten degrees, although with a coma the "disk" might have been larger. The earlier estimate was based on the slimmest of data. It should be expected, however, as I have also mentioned earlier, that Earth should have slowly distanced itself from Saturn as the coulomb charge of Earth increased.

For Earth, perhaps a distance of 2.8 million miles below Saturn is not unexpected. The White Crown of Upper Egypt seems to depict this situation. The bulb at the top of the bowling-pin shape, which would be Saturn (but could also be Mercury), has been reduced to a size smaller than Mars (where I suspect Mars is depicted as the pharaoh's head).

At a distance of 2.8 million miles, Saturn would look three times as large as the Moon does today. Mercury, located one quarter to a half million miles (400 thousand to 800 thousand km) below Saturn, would have looked considerably larger with its atmosphere and coma. Mars was much further from Saturn and would have remained a speck except when it lowered to earth. We cannot tell too much from the depiction of the Red and White Crowns, however, because these images probably depict Mars at its closest approach to Earth in the period well before 3147 BC. [\[note 9\]](#)

The location of Earth with respect to Jupiter can also be verified from the description of Noah's Ark. The crescent seen on the bottom of Jupiter looked like a boat or ship, probably equal to the first quarter of the Moon (but at the bottom of the sphere). For this the Earth would have to be a considerable distance vertically below and at an inclination of perhaps 45 degrees. Thus Earth might have very well have been located some 3 million miles (5 million

km) below Jupiter and 3 million miles away horizontally.

The distance between Saturn and Mars, listed in the chart above, also is not correct. If Mars and Mercury were carried off by Saturn from the "collision" location of 3147 BC, then the vertical separation should be calculated for a distance from the Sun greater than 0.7 AU. If we assume that these two planets were not released until the edge of the Asteroid Belt was reached, then a distance to the Sun of maybe 2.0 AU would be more appropriate. That would place Mars about 2 million miles (3.25 million km) below Saturn at the time of the delayed release. The same calculation for Mercury does not result in a sensible figure. [\[note 10\]](#)

... coincident orbits

As Saturn approached Jupiter, with Venus in orbit above Saturn, and with Mercury, Mars, and Earth some distance below, the small planets might have experienced an electric repulsion or attraction from Jupiter (when the plasmaspheres touched). The resulting interactions would have been somewhat unpredictable, and any number of things might have happened. But in fact it seems that the electric field of Jupiter was never experienced by the four small planets. It would, at any rate, have completely destroyed the Earth. The gravitational attraction of the Sun prevailed for both Earth and Venus; both at once assumed new orbits around the Sun; Mars and Mercury followed 80 years later.

This suggests that Saturn's plasmasphere almost instantaneously reshaped to account for the contact with Jupiter's plasmasphere, leaving the distant planets Venus and Earth free from the electric fields and the electric interactions, and thus subject only to the gravitational force of the Sun.

Mars and Mercury, closer to Saturn, seem to have remained within Saturn's plasmasphere, to be released at a later date, probably when Saturn entered the asteroid belt some 80 years later. At which time its plasmasphere would have contracted, or, if you like, the "gravitational sphere of influence" reduced in size. Isis hides the newborn Horus among the bulrushes of

the swamp. The swamp is the Absu. [\[note 11\]](#)

Uranus moved to a larger orbit immediately, initially moving to behind Jupiter. On the second orbit of Earth around the Sun after the flood, the raven is seen behind Jupiter, seeming to move closer to Jupiter's "mountain" as the Earth approached the location of the planet (in the night sky), and then seen moving away again as Earth passed Jupiter. *"And he [Noah] sent forth a raven, which went to and fro, until the waters were dried up from off the earth."* The raven is also mentioned in the Sumerian flood story. [\[note 12\]](#)

Having shot past the point of the collision, the Earth (and Venus) moved up from its previous orbit below the Sun's equator, making the Sun again one of the focal points of its elliptical orbit, in effect changing the inclination of its orbit with the Sun's equatorial. Venus would settle on an orbit nearly duplicating the prior orbit of Saturn, and thus end up with a perihelion close to the Sun, probably as close as Saturn had come in the previous era.

Earth and Venus both would have had their aphelion at the location of the "collision" between Saturn and Jupiter -- 0.72 AU or 0.79 AU -- with Venus, because it started above and away from Saturn, having its furthest location from the Sun at a somewhat greater distance than Earth. This would result in having the orbit of Venus extend beyond the orbit of Earth in the future.

Mars and Mercury ended up with orbits of the greatest aphelion, perhaps two AU or more, since apparently they were released later, when Saturn had moved into the asteroid belt, and probably within a short time of each other. I suspect, however, that the planets were released simultaneously. Thus Mars assumed the largest orbit, and, apparently overran the orbit of Earth, periodically coming very close to Earth, likely at 30 or 40 degrees north. Mercury also crossed over Earth's orbit, but I suspect it never got close to the Earth's surface.

Mercury, originally some million miles or more above Mars, would progressively shorten the separation between Mars and Mercury as it neared the Sun. At the location of Earth, Mercury intersected the Earth's orbit perhaps at a location only a few ten-thousand miles further north along Earth's surface.

We have what seems like records of the sightings of these two planets near Earth in the Palermo Stone, and in the lists of the names of the pharaohs of two dynasties in Egypt, and the list of Kings at Kish in Mesopotamia, but nothing much of a record of destructive interactions by Mars, except for some casual mention by Manetho. This is certainly also true for the periods of 1100 years into the future, at the time of the destruction of Sodom and Gomorrah, and 2200 years in the future, the destructions of the 8th and 7th century BC. Even for the destructions of the 8th century BC we know more from archaeology than from any contemporaneous records. There were few people left alive to record the destructions.

It seems likely that Mercury showed up repeatedly near Earth, as the precession of the orbits of these two planets completed an 1100-year turn around the Sun. Nabu (Mercury) became a

very popular name in about 2000 BC.

What is being described here is based on later interactions of the inner planets, observations which have come down to us from remote antiquity, plus the facts we currently have at hand, which include the present conditions of the Solar System.

"He also sent forth a dove from him, to see if the waters were abated from the face of the ground." Venus nearly followed the old orbit of Saturn around the Sun, but from a location somewhat above Saturn in 3147 BC. The orbit of Venus is today inclined about 3.61 degrees to the equatorial of the Sun, the second least inclination (after Mercury at zero degrees). Saturn's orbit is inclined at 4.51 degrees to the Sun's equator, the third least in orbital inclination.

The mythology of Greece holds that Venus was "born" from the "skull" of Zeus (Jupiter). This was seen on the first circuit of the Earth on its new orbit around the Sun. To the Greeks the first sight of Venus was as it first appeared from behind the globe (the skull) of Jupiter -- rather than from behind the mountainous outpouring of plasma at its south pole which was understood as his body or garment. [\[note 13\]](#)

The dove returned to the ark on the mountain, as seen from Earth. After the second circuit around the Sun the dove returned with a green branch -- Venus had developed a green cometary tail of ionized Hydrogen gas. On the third orbit the dove flew out again but did not return. Earth and Venus had relocated on their orbits so that Venus could no longer be seen as an outer planet. At least, that is my opinion as to what happened.

Mesopotamian "flood mythology" mentions that a swallow was also released to test the waters. My first thought was that this might have been Mercury, but Mercury was not available directly after the flood of 3147 BC. Mercury was traveling with Saturn, and only appeared 80 years later. Mercury was available from 80 years after the flood, and also again after 1100 years later, that is, at the time of the fall of the Absu and the blood seen in the sky. It would have just started to approach a periodic intersection with Earth's orbit a few hundred years before 1936 BC -- the destruction of Sodom and Gomorrah.

Earth would start to orbit the Sun with an inclination of seven degrees to the equator of the Sun. This was determined by how far below the other planets Earth was located in 3147 BC. As I have demonstrated, the separation between Earth and the other planets can be determined from the current orbital inclination to the equator of the Sun. Once a planet starts to circle the Sun there is no urgency to change its inclination, except through the minute periodic gravitational attraction of other planets.

Plasmasphere Interactions

A plasmasphere tail has to "strike" the plasmasphere of another planet to make electric field

contact. With the planets all orbiting at different periods and at different inclinations to the ecliptic, this would be a very infrequent event, and would only happen when two planets were both in line with the Sun -- thus at the equinox location of both planets.

The interior of the plasmasphere tail is the medium for electric forces, but the edges (the double layer) of the tubular tail are more likely to be the conduit in a contact involving an arc.

Gravitational effects increase and decrease with the distance between planets, and are sensed past plasmasphere boundaries. Electric forces are experienced only within two plasmaspheres after they touch and merge, and there is a line of sight between the two planets. It is these sudden forces which were recorded as planet shocks of antiquity. Examples of shock damage below.

Planet Plasmaspheres

Since all Solar System planets present themselves as electrically negative, the force would be repulsive. The start of the interaction would be followed by a rapid decline -- as one of the planets induced an opposite charge in the facing surface of the other. With the added induced charge the voltage difference between the two planets would increase rapidly, and it is this which will cause electric arcs to travel from one to the other.

Planet Plasmaspheres

The difference in the electric potential between the planets would cause attempts at charge equalization -- an electric arc (lightning) would strike from one planet to the other. The lightning strikes, however, would be a secondary action compared to the initial repulsive forces. Also, the lightning would take time to travel, for it is a physical transfer of charged

particles. When traveling millions of miles it might be seen approaching Earth.

All interaction would eventually stop because both planets continue in their travel around the Sun and would pass each other -- the inner planet traveling faster. The electric field interactions would end as the individual plasmaspheres of the two planets would separate and reform.

Gyroscopic Reaction

The Earth's axis would twist if the initial jolt were delivered off-center to the center of the Earth (above or below the equator). The wrenching of a planetary axis would exhibit a sudden onset in response to the shock, and then start to swing in a circle as the torque of a gyroscopic reaction sets in as a response. (This is explained further below.) The twisting motion of the reaction torque would decline as the applied force decreased and then would slow but would continue to twist the polar axis in the direction of a correction.

The axis would be twisted, but the inclination of the axis would return to where it started from, for the reaction torque would decrease and cease as the axis again approached its initial location (where it initially pointed to in the dome of the stars). The order of the seasons might change, but only temporarily. The energy of the impact would be dissipated in heat, in the relocation of the planet to a new orbit, and in a change in rotational speed.

One would wonder why electric field interactions between the inner planets were not more frequent. It depends on a number of factors which are listed below. I'll use this listing also to suggest the mechanics of the interactions, and explain the reaction torques.

1 -- Although the tails of the plasmaspheres of planets extend millions of miles away from the Sun (30,000,000 miles for Venus today, 40,000,000 miles for Earth), they are in effect blind. They remain blind to the electric charge of any other planets, and do not even "see" the plasmaspheres of other planets they may be nearing.

2--Plasmasphere tails extend away from the Sun, in the direction of the decreasing electric field, and in the past were seen in glow mode (as most comet tails are still seen so). Today the plasmaspheres of all the planets are in dark mode. Only if two planets are directly in line with the Sun could the plasmasphere of an inner planet reach the plasmasphere of an outer planet.

Venus, because it has an atmosphere, would have had a large and bright coma, and two distinct tails. One consisting of ejected (repelled) particulate matter, the other composed only of ions in glow mode at the edge of a plasmasphere tube. The first tail (of ejected material) might curve because the material is left behind after being repelled from Venus. It would also likely split as the charged particles are repelled from each other.

The other tail is defined by the electric field of Venus and the Sun, and is straight, like a

shadow. The ion plasma tail can redefine itself in seconds, even as Venus curves away on its orbital travels around the Sun.

Mars, without an atmosphere, had a very closely held coma, perhaps composed only of dust, with a tail composed of ions and electrons borrowed from the Solar Wind. The records of Mesoamerica, that twice (out of four close approaches) Mars was seen approaching Earth as a "mighty demon bat" (after 747 BC), suggests that perhaps the dust-envelope extended into space away from the planet and was warped by the Earth's magnetic field as Mars entered the Earth's plasmasphere.

Velikovsky, in *Worlds in Collision*, has collected similar images from many sources, depicting Mars as a sword, a wolf, and other shapes, also for the 8th and 7th centuries BC.

The plasmaspheres of planets on adjacent orbits will not make contact very frequently. Today the Earth and Venus line up exactly with the disk of the Sun only four times every 243 years (technically known as a "transit event"). These four transits are grouped in two pairs (with each pair separated by 8 years), at 129.5- and 113.5-year intervals.

The reason for this should be obvious: since all the planetary orbits are tilted at diverse angles to the equatorial of the Sun (the orbital inclination), and planets travel at different speeds, the likelihood of an alignment of two planets and the Sun is low.

In antiquity, the period at which Earth and Venus lined up with the Sun seems to have been 52 solar years from 2349 BC through 2193 BC, and near 48 or 50 years at other times. The so-called "52-year period" is discussed separately below.

This suggests that the orbit of Venus changed very little over the complete span of all the interactions -- during the course of some 3000 solar years. In fact, from various estimates of the orbital period of Venus derived from Mesoamerican calendrical sources, it seems the period of the orbit of Venus changed by only two days. I'll address this peculiarity below.

3 -- The plasmasphere tail of a planet would completely bypass another planet if the line of sight from the Sun passed above or below the other planet, even though the plasmaspheres of the two planets come relatively close to each other. For Earth the "closeness" would be measured at about 30 planet diameters, 240,000 miles (386,000 km).

4 -- If the edge of the plasmasphere tail brushed the plasmasphere of another planet it would probably have little effect, although there might be an exchange of the ions constituting the double layer, which might be detected by either planet. A direct hit of repulsive electric field force might be avoided, but lightning strikes could still happen via the double layer of the plasmaspheres. [\[note 14\]](#)

5 -- If the portion of the main body of the plasmasphere tail runs into the plasmasphere of another planet there will be a sudden realignment of the two plasmasphere surfaces so that

the two planets become enclosed within a single plasmasphere. Of course "sudden" is relative, for it involves the selective separation of ionized particles. It may take a minute.

After two plasmaspheres have merged, and there is a line of sight between the surfaces of the two planets, each planet becomes aware of the electric field of the other planet and both will experience the physical shock of a sudden repulsive electric force. (All planets experience each other as negatively charged, except Saturn.)

This electric force is not to be neglected, especially since it will be experienced suddenly and at full force. The two shocks experienced by Earth in 747 BC and 686 BC were of this nature. It could jog a planet to a new orbit (as in 747 BC), for it would always be experienced at a right angle to the orbital path. The two planets would be physically propelled away from each other. (But this is not always the case; see "686 BC" below.)

A stupendous seismic shock would be experienced which would travel around the Earth. At the location facing the other planet, the crust would be depressed, uplifting adjacent surrounding areas. This can be seen at the Caloris basin of Mercury, which extends over

about one third of a hemisphere (see image, further below). As the Earth continued to rotate, the depression would move toward the southwest as the Earth tilted away from the impact (for the northern hemisphere) and continued to rotate to the east. The force of the impact would cease as a change in the charge was accomplished through induction. The force on the crust (on one hemisphere) would transmit to the mass of the Earth, moving it to a different orbit away from the Sun.

Gravity acts throughout the whole of a mass. The effects can be modeled as if the force of gravity acts through a single point at the center of the Earth. An external force can similarly be modeled as if it acts through the center of the earth, but located along the central spin axis away from the center. This force, even if it moves a planet, will have no effect on the Earth's spin.

The actual electric field force is applied to the crust of the Earth (not to the interior), and on the portion facing the other planet. The other hemisphere of the Earth would be in the shadow of the electric field of the Earth and would not experience an electric field force from an exterior object. The impacting surface force would, of course, be transmitted physically to the whole Earth.

The Caloris basin of Mercury and the Orientale basin of the Moon are both circular because Mercury and the Moon did not rotate very fast when they were hit, although another likely cause for the circularity of the impact basins is that the duration of the forces was very brief.

The depressions on Earth, if they are found, would exhibit a semicircle of raised mountains on the western or southwestern side and flat region on the other side. The flat region would indicate the direction of travel of the Earth's surface at the moment the repulsive force was applied or directly after. The application of the exterior force would have traveled in the opposite direction -- in the direction of the semicircle of shoved-over mountains. The lack of mountains at the eastern edge is the result of the Earth's surface moving away from the location of the impact, due to the rotation of the Earth and the tilting of the Earth's spin axis away from the point of impact -- a combination of the external force, the gyroscopic reaction, and the rotation of the Earth. I'll detail the reaction torque below.

There should be four of these semi-circular areas dating from the last 4000 years. These should be recognized as being recent, that is, represent surface scarring which shows none of the marks of millions of years of weathering. There should be two very large impact basins from the passage of Venus in 2349 and 2193 BC. The contact of 1492 BC was made in the Pacific and left no mark on the land. [\[note 15\]](#)

[Image: View over Alabama. Courtesy of Dennis Cox,
<http://sites.google.com/site/dragonstormproject/>]

A second set of marks would represent the contact with Mars in 747 BC and with Mercury in 686 BC. The events by Mars and Mercury would cause much smaller impressions. The impact of 686 BC by Mercury can be generally located from "legendary" observations of North American Indians, and placed with considerable certainty in Northern Alabama. There will be no tribes indigenous to this area which would be able to tell tales of such events. There will be much later earthquakes just west of this area.

At first I suspected the mark of the 747 BC event to be located in Northern Mexico, just south of the Mexico-US border, south of Manuel Benavides, as suggested by Dennis Cox. The location of the semi-circle of raised mountains in this case points away in the "wrong" direction from the center of the impact basin -- in an arc from north to east. The "wrong location" of the crushed and shoved-over mountains is difficult to justify as an impact location. Additionally, the size of the basin seems far too small (the circle in this image is only 17 miles, 27 km, in diameter).

Cox attributes the burn damage to a "comet" exploding above the surface, as is proper to do among mainstream academics, and a lead followed by Cox. I would suggest arcing from Mars during the 8th and 7th century BC. The burn damage looks to be a cathode burn mark from a massive electric arc. The mountain ridges which show up at the northeast edge of the 17-mile-diameter circular mark are more or less coincidental. They are not shoved-over, but

only molten.

There is additional similar large scale burn damage further north of this location, pointed up by Michael Steinbacher in a paper "A new Approach to Mountain Formation" (in *Proceedings of the Natural Philosophy Alliance* Volume 8, 2011), which is not about mountain building as much as it is about the melting and burn damage of canyon edges in the southwest of the USA. The latitude is the same as that of the passages of Mars over the Middle East. This does not, however, constitute an impact area like what we are looking for.

At this point I do not know where the impact of 747 BC ought to be placed.

6 -- The force acting on one hemisphere would represent an unbalanced force if there was any misalignment with the other planet, and the force was experienced above or below the equator, that is, either in the northern or in the southern hemisphere.

This will be recognized as an externally applied torque to the spinning Earth. The reaction to an external torque is a twist (a reaction torque) with an axis at a right angles to both the spin axis and axis of the applied external torque. This is thus an interaction between **three** vectors.

First: The spin axis of the Earth may be considered the first of the three rotational vectors. It points in the "up" direction, and the spin is counterclockwise around this axis.

Second: An off-center force (shown as applied above the equator in the sketch) applied from the direction of the Sun (the direction of an inner planet) would present a rotation about an axis defining the forward motion of Earth on its orbit. This is the second vector. In this example, it would attempt to rotate the top of the spin axis away from the direction of the Sun.

Third: The third vector is the resultant gyroscopic reaction, and is defined as a rotational

axis at a right angle to the other two vectors, and thus (in this example) pointing away from the Sun. The rotation about this axis is also in the counterclockwise direction so that it will initially attempt to move the Earth's spin axis away from the forward direction of orbital travel.

7 -- Seen from above the Earth, the axis will thus dip (tilt) away from the Sun and away from the forward travel of the Earth (in the first example). Seen from above, the tip of the axis will seem to be rotating in a counterclockwise direction. Seen from Earth (looking up toward the north) the rotational axis will seem to describe a clockwise path through the dome of the stars (facing north). The stars at the pole will rotate through the sky in the opposite direction from normal.

B -- Torque Applied Below Equator

An unbalanced force applied to the southern hemisphere would result in a tilt of the spin axis of the Earth in the direction of the Sun. The reaction torque is the opposite -- it will attempt to tilt the axis in the direction toward the travel path along the orbit.

Note that in the diagrams above, the Earth's spin axis is shown perpendicular to the plane of the orbit. This is never the case. It is shown in this manner here for the sake of graphic simplicity.

Note also that I have neglected any possible longitudinal misalignment. If the compressive force first appears in the northeast, for example, there will be the additional twist of the Earth's axis away from the southwest. This would also likely pile up shoved-over mountains on the southwest side of the circular compression mark.

The spin axis of the Earth, and the Earth with it, would swing its axis through a loop -- at least as long as the spin axis remained in motion. In the case of a force applied above the equator, the axis will swing through a loop because it is being forced simultaneously to tilt away from the Sun and at a right angle away from the forward direction of the planet's travel

-- "backward," if you like. (The strange result of this is to have the region in the northern hemisphere and below the axis turn faster toward the east.)

The reaction torque will start up instantaneously and will continue to exert its force to counter the motion bending the spin axis away from its initial direction in space. The result is a precession of the axis -- a wobble, like a spinning top which is slowing down in rotation, except that the wobble will not continue, for the Earth, after all, is not a top placed on a table.

[\[note 16\]](#)

The start of movement of the spin axis after a shock starts quickly but smoothly, for inertia has to be overcome. Inertia is the resistance of objects to a change in movement. Anything loose from the Earth, like the oceans and the atmosphere, might resist the start of the changed motion of the crust, and move in the opposite geographic direction, although mostly the motion will be limited to a reaction to the initial shock. The start and progress of the reaction torque will consist of a smooth transition.

Once the motion is started, the same resistance to a change would guarantee that Earth's axis would continue its circular wobble, but the rate of movement would drop rapidly as the external torque is removed. The reaction torque would shift value continuously to bring the Earth's spin axis back to the location it started from.

This, by the way, is how a gimballed navigational gyrocompass works. It is a device which can be twisted, turned, flipped, and the axis of the spinning gyroscope will continue to point to the same location in space, because it is free to move on all three axes. The fact that the spin axes of all the planets still align either within a few degrees with the Sun's spin axis or are inclined 31 to 32 degrees away from the Sun's axis, confirms the fact that the gyroscopic reaction -- the wobble -- will return the axis to the location it started from.

8 -- When the plasmaspheres merge, the planets will also recognize the charge difference between them and will attempt to equalize charge, first by inducing a change in the charge of the facing hemispheres. This changes the repulsive electric field force to an attractive force, mostly felt by the crust. The oppositely induced charge increases the voltage difference between the planets and an electric arc might strike between the planets to equalize charge -- a lightning strike which could travel millions of miles within the highly conductive interior of the plasmasphere (or, as likely, along the double layer of the outer edges). Once struck, an arc will continue even as distance increases. The bolt could sweep around the planet if it struck laterally, for Earth would continue to rotate.

The 8 items considered above explain why "collisions" were so infrequent. But also point up that the actual interaction could be absolutely devastating. Between 3147 BC and 685 BC Venus passed the location of Earth some 3500 times, yet in only a few instances was there any recorded interaction with Earth, even though Venus may have "come close" many times.

Seven instances are noted (for Venus) in Mesoamerican sources (four of which probably in the period of 2349 BC through 2193 BC). Egyptian sources (as the cow of Hathor) also suggest seven events. Overall, in only three instances was the orbit of the Earth changed significantly enough to have been recorded as calendar changes.

As presented above, the method whereby Earth changed its orbit always involved a displacement radially away from the Sun. Earth apparently never moved toward the Sun. The inclination of the planet's orbit would remain the same. From this follows what I proposed earlier, that the inclination of the orbits of the planets has not changed significantly in 5000 years since 3147 BC. There was a change in the axial inclination of the Earth in 685 BC, but this was likely due to a giant 40-day coronal mass ejection.

It could be suggested that two planets might be off from being exactly in line with the Sun by the diameters of their plasmaspheres. Then the thrust to a new orbit would be at a slight angle to the original orbital inclination. But for the combination of Earth and Venus this difference in alignment would not be much more than about 30 planet diameters, thus about 240,000 miles (386,000 km). This displacement is totally insignificant compared to the radius of Earth's orbit -- 93,000,000 miles. I do not think, therefore, that even under these possible unusual conditions the inclination of the orbit would change by even a fraction of a degree.

Lastly, it should be noted that Venus would react quite differently to a plasmasphere contact. Venus has an extremely heavy atmosphere, nearly 100 times the density of the Earth's atmosphere. It is like an ocean. Because of its density and the 700 degree Fahrenheit surface temperature, the atmosphere is the location of Venus's exterior electric charge.

The dense atmosphere would therefore be the location of the electric forces impinging on Venus in meeting another planet. But rather than being transmitted to the surface of one hemisphere, the forces would be absorbed by the atmosphere and distributed around the planet, buffeting the crust with a compression wave from all directions. The planet would not likely relocate to a new orbit, and in fact it looks like the orbital period of Venus has not changed significantly since 3147 BC, except for becoming circular at some point after 685 BC.

Lightning Strikes

About the absolute devastation of extraterrestrial lightning strikes, Dennis Cox, who has investigated altered landforms, has pointed out that the results of the initial lightning strike would have been absolutely stupendous. I have quoted from his website in Chapter 23 ("Destruction by Mars").

Cox writes from the experience of having seen the landscape. He is a welder and welding inspector, and can recognize the molten forms, even though they are rock instead of steel. But his causes are constructs from the limited imagination of the scientific community -- a

dreamland of comets and meteors which doesn't exist.

We have, additionally the data from the Chicago Fire of AD 1871. This was not an electric arc from a planet, but a very similar blast from the heavens, not unlike the secondary effects of a planetary arc. Quoting from contemporary sources of the 19th century, the link to the Chicago Fire at [\[thunderbolts.info/tpod/2006/arch06/060206chicagofire.html\]](http://thunderbolts.info/tpod/2006/arch06/060206chicagofire.html), reads:

"[the flames] absolutely melted the hardest building-stone, which had previously been considered fire-proof. Iron, glass, granite, were fused and run together into grotesque conglomerates, as if they had been put through a blast-furnace."

"The huge stone and brick structures melted before the fierceness of the flames as a snow-flake melts and disappears in water, and almost as quickly. Six-story buildings would take fire and disappear forever from sight in five minutes by the watch."

These are reports from Chicago. Conditions in the rural town (and region) of Peshtigo, Wisconsin, in the same year (AD 1871) and at the same time on the same date, describe giant balloons of fire dropping from the sky. Balloons in the 19th century were not the foot-diameter toys of today, but gigantic spheres the size of houses. A second entry at thunderbolts.info continues with:

"Most, if not all [of comets], are as rocky as asteroids. The result of their fragmentation will be a meteoric shower of granulated silicates, or sand, mixed with flammable gases and electric discharge phenomena - a 'biblical' rain of fire and sand."

If I recall correctly, there is some reference in Isaiah or Jeremiah about hot sand blowing in the windows of houses, or under the doors. But this sand is not due to fragmentation, but is the result of the complete disintegration of the silicates. It is a fine powder, with the particle sizes of clays. It is the result of cathodic lightning bolts playing on the rocky comet. Thus "flammable gases" or atmospheric Oxygen are not needed. The silicates will be incandescent from their electrification: electrons in glow mode will envelop the grains as a "space charge."

A continuation of this partially quoted essay by Cox likewise suggests that: "Comets discharge carbon compounds that would be flammable in the Earth's oxygen atmosphere." Again, none of this is needed. The fire will be there -- as burning incandescent dust.

I would object also to the "detonation shock." Cox here assumes a replay of the 1908 Tunguska detonation in Siberia. But, except for the wind, the events would have been nearly silent. The eyewitness reports from the Chicago Fire and the Peshtigo Fire report that the fire was silent except for a roar of a tornado-like wind.

The charge equalization might have involved repeated single lightning strokes, or involved a lightning strike which did not let up, but continued to blast and travel mile after mile. For Mars between 806 BC and 687 BC, we should expect the arc to be tens of miles wide and fall

like a sheet of fire. But this is at the eye of the hurricane. The effects at the edges would have extended maybe hundreds of miles. This would be a rotating whirlpool of soil, dust, molten rock, and flaming incinerated forests.

As the planets start to distance from each other the plasma would turn to glow mode and dissipate at the atmosphere. Even a number of full days of arcing will not equalize the charge between planets, as Juergens has pointed out. A lightning strike which would carve the Grand Canyon (a bolt which is suspected to have arrived from Saturn) would only reduce the charge of the striking planet by a fraction of a percent.

Compression Marks

If, as I have suggested, the Earth has experienced massive compressive forces a number of times due to the line-up with another planet, we should be able to search the Earth's surface for compression marks. Two stand out clearly, a crescent of mountains in the Himalayas, and a smaller similar semi-circle in Northern Alabama (US).

"Documented," as used here, means that we can follow a trail of what was seen and was recorded in legends and myths worldwide. "Suspected" means that there is a trail of destruction which points to an inception somewhere east of the string of destruction sites.

Before setting out some details, let me list what little we know of the impacts. The following lists the compression marks since 3147 BC:

There are other suspect locations, marked by crescents of mountains -- Northern Mongolia south of Lake Baikal, and the Elburz mountains south of the Caspian (edging on Northern Iran). In all cases (including the land contacts in the list above) the crescent is in the south or southwest of what would be the contact area for the northern hemisphere. This shows that the Earth immediately tilted away at a rate much greater than the normal displacement of the Earth's surface due to rotation. This is to be expected, for if the shock moved mountains, it must have been stupendous.

year of impact	agent	suspected location	comments
10,900 BC	Saturn	Hudson Bay	obvious
2349 BC	Venus	Tibet	obvious
2193 BC	Venus	Central Asia ?	only suspected
1492 BC	Venus	Central Pacific	good evidence
1440 BC	Venus	unknown land ?	undocumented
747 BC	Mars	Central Asia ?	suspected
686 BC	Mercury	North Alabama	documented

What I will do in the following is to describe the likely sequence of an impact. The reader should realize that although the "impacts" were local, these were induced from afar -- for Venus at distances of 20 million and 10 million miles (32 million and 16 million km). In three diagrams below I'll relate what seemed to have happened at the locations where we

have some evidence. But first there is a need to look at two other "impact craters," the Moon's Mare Orientale basin and Mercury's Caloris Basin.

First of all, we could expect these two impact marks to be circular. If a planet remained standing still, that is, not rotating (or nearly so), the reaction torque would not send the planet into a spin which changed the location of the impact. This seems to be the case for the two very large circular marks on the Moon and Mercury.

Additionally, if the compressive force was applied at the equator of a planet, there would be no applied torque, and thus no gyroscopic reaction torque. A circular mark would be made. This might be suggested for the Caloris Basin of Mercury.

Going by the record of Mesoamerica, the Moon's Mare Orientale was likely formed shortly after 2349 BC. Mercury's Caloris Basin was probably created in 686 BC. (Mercury's Caloris basin will be described further below.) Both consist of rings of mountains and circular flat planes, surrounding a flat central depression.

The ring of mountains of Mercury's Caloris Basin is 963 miles (1,550 km) in diameter. The Moon's Orientale Basin is 578 miles (930 km) in diameter.

[Image: Mare Orientale basin of the Moon. After NASA.]

Orientale Basin is located at the extreme lower left edge of the Moon, as seen from Earth. The Orientale Basin is overlaid with younger craters, although it is thought to be one of the "youngest" craters or basins. Although lacking any evidence, it is held to be 3.9 billion years old by Establishment Astronomers.

The Mare Orientale, unlike the other circular depressions on the Moon (the Mare basins), is not a flat field of flood basalts, that is, melted rock resulting from an extended electric arc. The Orientale ejecta extends beyond the 600-mile (966-km) diameter of the rings for another 300 miles (483 km), and "contains linear patterns that point back to the center of Orientale" (Wikipedia).

The peculiar overall shape of both the basin and its ringed structure was likely created with an initial repulsive impulse which depressed the central area, causing the outer edges to lift in response. The outer ring of mountains was caused by fracturing of the crust which was pushed away from the center (overthrust). Stone and rock will fracture at a 60-degree angle from the point of impact of a blow. With both the surface of the small planet and the applied force angling away from the center of the impact area, the breaking of surface rock would happen at a low angle to the surface. Together with forces directed away from the center, this would shove a ring of crust onto the adjacent exterior surface. The drag encountered by the moving material would crumple the displaced crust into mountains.

The interior basin, on the other hand, stretched in subsiding from compression and fractured in shear (faulting, a process whereby a section of land drops down). The Caloris Basin of Mercury is noted for "lava plains," and "radial troughs." "The exact cause of this pattern of troughs is not currently known" (Wikipedia).

Within seconds of the onset of "seeing" the exterior negative voltage, electrons of the planet with a lesser charge would be chased away from the region, and the crust of the planet facing the other would assume a positive charge. That would rapidly dissipate the repulsive electric field force, and change it to an attractive force instead. The sudden withdrawal of the repulsive force would allow the depressed center to relax and raise itself again, with the result that the raised outer rings would then start to subside. The following lifting force will have the same effect.

Because the lifting force (or the negation of compressive force) builds in magnitude over a period of time (although this could be short), it will not cause the shock-induced damage of the initial compressive force. The initial shock is not to be neglected, however. It is this which probably makes the central depression look like a relatively smooth lava field, as it may also have done to the smooth outer ring. Rock melted and flowed like wet clay from the heat generated by compression.

As the subsequent force provided a lift, it would have seriously aided the recovery, making the two regions of the Moon and Mercury look more like car dents which have been hammered out.

Both Mercury and the Moon show crustal damage at the antipodal locations from the impact marks. Astronomers have identified these as being the result of shock waves traveling from the Orientale Basin of the Moon and the Caloris Basin of Mercury to meet at the location directly opposite -- all the way around the Moon and Mercury.

... Hudson Bay impact

The Hudson Bay impact has been described in an earlier chapter.

... Himalayan crescent

The crescent of mountains representing the Himalayas is a prime representation of a massive compression contact. The Himalayas were shoved from the north and northeast onto older mountains. I have not made much of this in the analysis presented in the text earlier, but it becomes obvious in looking at the Himalayas.

*[Image: Himalayan crescent and Tibetan plateau.
From NASA satellite image.]*

The Tibetan Plateau is nearly flat compared to the Himalayas. A satellite image is shown above. Actually, the Tibetan Plateau is a rugged elevated terrain consisting of what looks like buried mountaintops peering through. In the upper left is the Tarim Basin. In this image, India's lowlands appear below the Himalayas.

[Image: Himalayan mountains. Source public domain.]

If a compressive impact leaves a circular mark on a planet which does not significantly rotate, like Mercury and the Moon, the result is entirely different for Earth, which rotates through 360 degrees in 24 hours. The surface at mid-latitudes moves at 500 miles per hour.

A planet standing still will not respond with a gyroscopic reaction, for no other rotation is affected. The fast rotation of Earth, however, would cause an immediate gyroscopic reaction, a movement at right angles both to the torques of the applied repulsive electric field force and to the spin.

The initial reaction of the crust would be the same as for a planet which was not rotating. The center would be compressed and would subside. The edges would rise in response, but also be subjected to compressive forces. Because these impinge at an angle, the shear, which normally breaks rock (the crust) at a 60-degree angle from the direction of impact (as any bricklayer knows), would break the crust at an angle greater than 60 degrees to the normal of the surface, in effect "shoving" the crust ahead of the compressive forces.

The forces drop off unexpectedly rapidly from the center of the contact area. This is the result of combining the nearly parallel electric field due to the foreign planet and the spherical orientation of the electric field due to the Earth. In addition, the curvature of the Earth (or the Moon, or Mercury) is such that the effect of an exterior force lessens rapidly away from the center. The shock becomes directed to a nearly horizontal angle with distance from the center of the impact location.

planet	compression area	area Diameter	planet Diameter	planet Circumf	degrees subtended
Moon	Oriente Basin	578 mi	2159 mi	6783 mi	31 deg
Mercury	Caloris Basin	963	3030	9518	36
Earth	Himalayas	1700	7923	24891	24

What happens subsequently is that the Earth continues to rotate, thus the external force is applied to a region away from the initial contact. The direction the Earth moves, however, does not follow its normal rotation (to the east), but a direction determined by the impact forces and the gyroscopic reaction, which starts up immediately. For an impact to the northern hemisphere, the new direction to which the Earth's surface would move (with respect to an exterior reference) is toward the northeast, thus bringing the southwest under the external impinging forces. [\[note 17\]](#)

Thus we can define a lagging edge of the circle of impact (northeast) and a leading edge (southwest). The lagging edge now experiences reduced forces. The relaxation of the originally uplifted crust will be aided by this. Although I have shown the leading edge as uplifting or consolidating in the diagram above, this is not certain. What has happened at this juncture is that the compressive force has diminished as the external electric field induces a change of charge in this section of the crust. Electrons are chased away, and the surface becomes more positively charged.

At this point in time (and this could take only minutes), the compressive (repulsive) forces are failing and perhaps have become attractive, that is, the exterior planet now will attempt to lift the crust. This will aid the region of the initial depression, helping it back up, and causing the lift at the lagging edge to subside. But at the leading edge of the contact region the portion of the crust, which initially rose in response to the central depression, will rise even further (and cause an additional subsidence beyond the leading edge). The results of this are shown in the following diagram.

With the reversal of the value of the electric field between Earth and the exterior planet, an attempt would be made at charge equalization -- an electric arc would pass between the planets. In fact, the equalization arc might start up from the planet with the greater charge at the moment a voltage difference between the two is sensed (even with both planets at a negative charge).

Now we reach a problem. The compressive scar shows a sudden letup, but the cause for this is not at all obvious. The sudden cessation of the compressive forces cannot be due to an arc between the planets, for this would take much more time to be felt by Earth, in that the arc would have to travel from some remote distance.

For example, in 2349 BC, it looks like the arc from Venus traveled for approximately 6 hours, and was, in fact, a disconnected plasmoid bolt. From "mythological" sources, the bolt would have been enormous, and could have fried the Earth (at least, the Eastern Mediterranean region) if the initial shock had not tilted the Absu up to face the approaching plasmoid bolt. The initial release of the plasmoid from Venus would also have suddenly dropped the electric field of Venus, and it is this which suggests another cause for the sudden cessation of the compressive forces (long before the plasmoid arrived).

I am not entirely comfortable with this electrostatic simplification, especially the change of a portion of the Earth's surface to a positive value. We are here not considering a local thunderstorm, which will chase away surface electrons, but something immensely larger and

of a potential measured in billions of volts.

Obviously the initial repulsive shock was limited, and in fact, it fell off as suddenly as it had first started (or we wouldn't be here at all). It is the crescent of shoved-over mountains which shows that the repulsive forces stopped rather suddenly. Otherwise we would see the Himalayas spread across India and Pakistan like frosting on a cake. The same goes for the mountain ring surrounding Huntsville, Alabama, or the US Rocky Mountains.

I have covered the look of a "shoved over" mountain range, the Rocky Mountains, in the analysis of the "impact" of 10,900 BC in an earlier chapter. I realize that it seems almost inconceivable that an exterior repulsive electric field force would have been so stupendous that it would shear mountains off at their base and shove them over hundreds of miles, to be piled up in a crescent surrounding the center of impact. Yet this is what is indicated by the geological evidence. For the North American impact all plant and animal life was incinerated by that impact force.

The 52-Year Cycle of Venus

The interval between approaches of Venus was known by the people of Mesoamerica to be 52 years. This would initially have been derived from observation in the era of 2349 BC to 2193 BC. The 52-year period can be verified, or strongly suggested, if it is found that the synodic period for Venus is a near integral division of 52 Earth years. Assuming, initially, that the period for Venus was 225 days, as it is today, and the Earth's year was 260 days, the synodic period is:

$$260 * 225 / (260 - 225) = 1671.43 \text{ days}$$

This period divides into 52 Earth years as a near even integer value, or reasonable fraction, as follows:

$$52 * 260 / 1671.428 = 8.088$$

If it could be assumed that the period of repetition of approaches of Venus was an even 8 years, then the synodic period of Venus could be calculated as:

$$8 * 260 = 2080 \text{ days}$$

From this a more reasonable (believable) orbital period of Venus could be found to be 231.1 days.

$$260 * 231.1 / (260 - 231.1) = 2079.10 \text{ days}$$

I realize that this sort of math give some people cold shivers and may induce convulsions, yet is is perfectly reasonable, and the results from this reasoning fall into place with

unprecedented ease.

Period of 2193 BC to 1492 BC

For the period between 2193 BC and 1492 BC I have assumed an orbital period of 273 days for Earth, but the period of Venus has to be estimated. This is so because there is no data available, except what might be guessed after from calendar implementations. Since the Mesoamerican Haab calendar was not instituted until after 1492 BC, the 52-year coincidence of the Haab and Tzolkin calendars does not apply to this era. The Haab was meant to account for the longer 360-day year after 1492 BC.

If I was to estimate a time period when the 52-year coincidence might have been initiated from observation, I would suggest the period of 2349 BC to 2193 BC. Certainly after 1492 BC this was no longer true, both because of the very large increase in the Earth's orbit (at that time) and because the incident of the Sun standing still in the sky at the time of Joshua cannot be dated to 52 years after 1492 BC (as Velikovsky has pointed out).

The following table calculates the synodic period of Venus for values of orbital periods from 231 days to 225 days. The first value of the table (231) is the likely orbital period before 2193 BC; the last value of the table (225) is the most likely orbital period after 1492 BC. Thus synodic periods at either of these extremes are not legitimate values for this time period, but will be the limits in any calculations (as shown below).

----- Venus interval for the period of 2193 BC - 1492 BC -----									
Venus period	Synodic period	----- interval * 273 / synod -----							
		52 yr	51 yr	50 yr	49 yr	48 yr	47 yr	46 yr	45 yr
231	1501.50	9.45	9.27	9.09*	8.91	8.27	8.54	8.36	8.18
230	1460.23	9.72	9.53	9.34	9.16	8.97*	8.78	8.60	8.41
229	1420.84	9.99*	9.80	9.60	9.41	9.22	9.03*	8.83	8.64
228	1383.20	10.26	10.06	9.86	9.67	9.47	9.27	9.07*	8.88
227	1347.19	10.53	10.33	10.13	9.93*	9.76	9.52	9.32	9.11
226	1312.72	10.81	10.60	10.39	10.19	9.98*	9.77	9.56	9.35
225	1279.68	11.09*	10.88	10.66	10.45	10.24	10.02*	9.81	9.60
* - near whole values									

There is no continuity of dates at regular 52-year intervals between the four contacts by Venus after 2193 BC, and the first contact in 1492 BC. I suspect that in this intervening period (2193 BC to 1492 BC) the Venus cycle might have been something other than 52 solar years. The coincidence of the 52-year period between the Mesoamerican Tzolkin and Haab calendar is a mathematical construct which is independent of the actual seasonal calendar. We have no guarantee of what the "Venus cycle" was in actuality, but the synodic period for Venus can be tested against various values of the Venus cycle, using 52 years through 45 years.

I would reject orbital values nearer 225 days (today's value), since the catastrophe of 1492 BC caused a very large change in the Earth's orbit, and would have caused a proportional change in the orbit of Venus. It is thus more likely that a value closer to an orbital value of 231 days is a likely candidate. That suggests an orbital period for Venus of either 229 days or 230 days. I am selecting 229 days.

From information detailed in the chapter "The Day of Kan," it looks like there were 11 "sightings" of Venus in the 520-year period (called a "may") ending shortly after 1440 BC. From the above table, for an orbital period of 229 days, a reduction to 48 or 47 years would be suggested. Of these two, a 47-year cycle comes closest to filling the time interval from 2193 BC to 1492 BC with a nearly even number of intervals -- it comes to within 4 years of 2193 BC.

$$520 / 11 = 47.2$$

$$2193 - 1492 = 701 \text{ years}$$

$$701 / 47 = 14.91$$

$$47 * 15 - (2193 - 1492) = 4$$

Period of 1492 BC to 747 BC

It would seem that the Venus period would be firmly established, even though based on slim data, for the period of 1492 BC to 747 BC. The catastrophe of 1492 BC was followed by another contact in 1440 BC, "52 years later" -- suggested Velikovsky. However, the date of

1440 BC is very uncertain. Velikovsky settled on 1440 BC by applying the well-known Mesoamerican interval of 52 years. This was certainly the interval when Mesoamerica expected the end of the world, but it was based on the fact that the Haab and the Tzolkin calendar come again to the same day-name and day-number combination after an interval of "about 52 years." In actuality these were Tun years of 360 days, and fell 273 days short. In Mesoamerica it was thought that the Tzolkin calendar regulated the movements of the planets.

The Venus period therefore ought to be investigated in a manner similar to the chart above. The Earth's period was 360 days; the period of Venus should be less than 229 days and more than 225 days. There were no further contacts between Earth and Venus after 1492 BC (or 1440 BC). The possible contact of Venus with Mars in 776 BC is not likely to have changed the orbit of Venus significantly, since Mars is only 1/8th of the mass of Venus. Again, in the table below, we are looking for whole numbers or reasonable fractions.

----- Venus interval for the period of 1492 BC - 747 BC -----									
Venus period	Synodic period	----- interval * 360 / synod -----							
		52 yr	51 yr	50 yr	49 yr	48 yr	47 yr	46 yr	45 yr
229	629.31	29.7	29.1	28.6	28.0	27.4	26.9*	26.3	25.7
228	621.81	30.1*	29.5	28.9*	28.3	27.8	27.2	26.6	26.0*
227	614.44	30.4	29.9*	29.3	28.7	28.1*	27.5	26.9*	26.3
226	607.16	30.8	30.2	29.6	29.0*	28.4	27.8	27.2	26.7
225	600.00	31.2	30.6	30.0*	29.4	28.8	28.2	27.6	27.0*
* - near whole values									

For two reasons I would select a period of 225 days for Venus (which is nearly today's value). First, because the synodical period of 600 days shows up in calendars dating from this period as a whole number product of the period of the Moon ($20 \times 30 = 600$) and the period of the Earth ($5 \times 360 - 3 \times 600 = 0$.) Second, because it is most likely that the contact with Venus in 1492 BC reduced its orbit in proportion to the 100-day increase in the Earth's orbit. (The later change of the Earth's orbit in 747 BC was due to Mars, not due to Venus.)

Selecting a Venus cycle of 50 years moves the event of the Sun standing still for Joshua from 1440 BC to 1442 BC. This resolves the difficulty Velikovsky had in justifying a date of 1440 BC. I have not corrected this elsewhere in this text. A 50-year Jubilee of the Jews was instituted after 1492 BC. I do not know if this was the actual interval, or how it was counted, but it is suggestive.

Period of 747 BC to today

After 1440 BC there were no further "close calls" by Venus. The orbit of the Earth rounded later in 670 BC, which may have completely voided the condition. Mesoamerica, however, continued to celebrate "world endings," based entirely on the Haab and Tzolkin calendars, as it had always been. The period for this is 52 years of 365 days (18,980 days), which is

somewhat shy of 52 Gregorian years, but not enough to make much of a difference during this time.

Venus Crosses Earth's Orbit

From the above we have the following estimates of the orbital period of Venus for various eras. From this it can be found if Venus crossed Earth's orbit at any time.

----- Venus interval for the various periods -----				
time period	Earth period	----- Venus ----- period	synodical	Maya cycle
3147 BC - 2349 BC	240 days	up to 240	unknown	unknown
2349 BC - 2193 BC	260	231.1 days	2080 days	52 years
2193 BC - 1492 BC	273	229	1420.8	47
1492 BC - 747 BC	360	225	600	50
747 BC - today	365.24	224.7	583.9	52

Following below are some estimates of the orbit of Venus and Earth in terms of their perihelion and aphelion. This is of interest if it is held that planets "collide" when their orbits cross. The orbits of Earth and Venus were probably nearly the same at first (but not in the same plane), as would be expected, and likely crossed, but none of all the possible orbital crossings ever resulted in physical interference with each other. We certainly know that for certain; we are here to testify to this.

It should be realized that electric contacts would only happen when both planets crossed the equator of the Sun. The two planets have to be in a direct line with the Sun for the plasmasphere tail of an inner planet to be sensed by the outer of the two planets. The geometry of that condition defines an equinox for both orbits. A look at past electric contacts between Earth and other planets places each of them at or very near an equinox.

Using Kepler's Third Law, the average orbits can be found from $(T_{\text{Venus}} / T_{\text{Earth}})^2 = (r_{\text{Venus}} / r_{\text{Earth}})^3$, which is most easiest accomplished by setting the radius of Earth's orbit to 1, that is, 1 AU.

----- Venus interval for the various periods -----				
time period	Venus period	Venus orbit	Earth period	Earth orbit
after 3147 BC	unknown	unknown	240 days	0.75 AU *
after 2349 BC	231.1 days	0.737 AU	260	0.79 *
after 2193 BC	229	0.733	273	0.83
after 1492 BC	225	0.724	360	0.99
after 747 BC	224.7	0.723	365.24	1.00
* data from calendar analysis, Appendix A, "Chronology"				

In 2349 BC Venus and Earth might have approached no closer than 12 million miles, and more likely at a distance on the order of 17.5 million miles (28 million km). This was the estimate derived earlier based on the time of travel of a plasmoid from Venus to Earth and the

timing of eyewitness accounts around the world.

We can be fairly certain of the separation distance of about 12 or 17.5 million miles, for if Venus had approached Earth as close as (perhaps) a million miles, then, as many others have suggested, Earth would have been devastated by repulsive electric forces.

If in 2349 BC, Venus struck from a distance of 12 million miles, then we would expect the "contact" of 1492 BC to mostly repeat at the same separation distance. The orbits of Venus and Earth changed, but not all that much, and it would be reasonable to suggest that the planets would again meet under nearly the same conditions. In 1492 BC, if Earth and Venus were on circular orbits (which they were not), then they would have approached no closer than 9 million miles (14 million km).

$$(0.83 - 0.733) * \text{AU} = 9,021,000 \text{ miles.}$$

Yet, as we know, catastrophic interactions took place in 2349 BC and 1492 BC despite these immense distances. It would have to be suggested that the initial orbits of all the inner planets were eccentric, moving on part of their orbit much further from the Sun than estimates of the average radius of the orbits would suggest (the orbital period remains the same for eccentric orbits). We know virtually nothing about the eccentricity of the orbits of Mars and Mercury, except the suggestion that their orbits remained the same into the 7th century BC. We do know some things about the orbits of Venus and Earth, although the information is late -- also dating from the 7th century BC.

An investigation by Lynn Rose and Raymond Vaughan in 1974, of the 7th century BC *Venus Tablets of Ammizaduga*, found in the library of Assurbanipal, determined that the eccentricity of the orbits of Venus and Earth were still at 0.15 and 0.10 respectively before 670 BC, but Earth's orbit became nearly circular (0.01) in 670 BC. The eccentricity of Venus changed to today's value of 0.006 at an unknown later date.

I have suggested above that the period of Venus probably did not change significantly in remote antiquity. Using the eccentricity of 0.15 found by Rose and Vaughan, the perihelion and aphelion of Venus can be determined from the average orbital radius, the semimajor axis.

The eccentricity multiplied by the semimajor axis (the average radius of an orbit) will yield the amount by which the perihelion or the aphelion of the orbit (the closest and furthest distance from the Sun) differs from the "average radius" of the orbit. The perihelion of Venus, for example, in 685 BC, will be found to be:

$$(1 - 0.15) * 0.723 \text{ AU} = 0.614 \text{ AU}$$

The aphelion would be:

$$(1 + 0.15) * 0.723 \text{ AU} = 0.831 \text{ AU}$$

Assuming that the eccentricities found by Rose and Vaughan are indicative of earlier conditions, we could calculate the perihelion and aphelion of both Venus and Earth for various time periods and compare these to see if the orbits potentially crossed. First, for Venus:

Perihelion and Aphelion of Venus before 685 BC, 0.15 eccentricity			
time period	semimajor axis	perihelion	aphelion
after 2349 BC	0.737 AU	0.626 AU	0.847 AU
after 2193 BC	0.733	0.623	0.843
after 1492 BC	0.724	0.615	0.832
after 747 BC	0.723	0.614	0.831

Similarly the perihelion and aphelion of Earth can be found for various estimated orbits in antiquity as follows.

These numbers define orbits which potentially cross, since until 1492 BC the perihelion for Earth was less than the aphelion for Venus. (That they actually crossed would depend on the relationship of the two orbits.) What is certainly shown from the above table, is the possibility that the two planets were on genuine "collision paths" until 1492 BC. Since Earth was three times displaced to a larger orbit by Venus, then Venus would have to be inside the orbit of Earth at the moment an electric contact was made. Coming close to each other would be insufficient reason for interaction. To interact electrically the plasmaspheres of the planets have to touch. This only happens if two planets are in line with the Sun while "passing" each other, because the tails of the plasmaspheres of planets all point away from the Sun. [\[note 18\]](#)

Perihelion and Aphelion of Earth in antiquity, 0.10 eccentricity			
time period	semimajor axis	perihelion	aphelion
after 3147 BC	0.75 AU	0.675 AU *	0.825 AU
after 2349 BC	0.79	0.711 *	0.869
after 2193 BC	0.83	0.747 *	0.913
after 1492 BC	0.99	0.891	1.089
after 747 BC	1.00	0.990	1.010

* -- Earth perihelion falls within Venus aphelion

What I have shown above is the possibility of "collision" courses for Venus and Earth. This is a favored proposition of catastrophic analysis, despite the fact that crossing orbits will not likely do anything bad. But these crossings certainly bear on the Mesoamerican concept of the possibility of disaster based on 52-Tun year intervals, which was the condition between 2349 BC and 2193 BC. During this 150-year period Venus was seen to cross Earth's orbit, with disasters in 2349 BC and 2193 BC, and perhaps (likely) at other 52 year intervals.

But these events probably had nothing to do with Venus crossing Earth's orbital path. It was just that the crossing of orbits remained visible until 1492 BC. The Olmecs were right in instituting whatever ceremonies were required to prevent any further catastrophes. It worked, too.

The Orbit of Venus

Shown in the diagram above, Venus's elliptical orbit falls partially outside the Earth's orbit. The planet Venus would be seen between the Sun and Earth every two years or so, and would line up directly between Earth and the Sun at intervals of 700 or 800 years. These "meetings" would depend, among other things, on the slow rotation of the second nodal points of the orbits of Earth and Venus.

The orbit of any planet is an ellipse, with one "focus" (nodal point) at the Sun, and the other some distance away from the Sun. The second focus of an elliptical orbit slowly rotates (precesses) around the Sun. There will therefore be periods of hundreds or thousands of years where two planets would never line up. Precession of orbits is gravitationally induced and thus depends on how close the orbits of various other planets are, and the sizes of the planets.

Precession of orbits should not be confused with precession of the equinox (the intersection of the equatorial of the sky and the ecliptic). The equinox currently moves 50 seconds of a degree west per year. This is determined by the precession of the rotational (polar) axis. The complete precession of the rotational axis takes 27,000 years currently.

The second nodal point of Earth's orbit currently moves 10 seconds of a degree east per year in a counterclockwise direction as seen from above. Today the Earth's orbital precession takes 112,000 year to complete a full swing around the Sun. The location of the aphelion of the Earth's orbit (the part of the orbit where Earth is furthest away from the Sun, which corresponds to the location of the second nodal point) slowly moves in a circle around the Sun. Aphelion of Earth's orbit is today reached at about July 4th. The orbital precession of Mars is 43,000 years today. [\[note 19\]](#)

In the case of Earth and Venus, there would be a series of "close calls" when the precession of the orbits caused the two planets to reach the same radial location around the Sun at the same time. The close calls would be spaced widely apart in time, for it would depend on the ratio of the lengths of the orbits of the two planets, and additionally would only occur when

both planets crossed the equatorial of the Sun at the same time and at the same radial location (angle) with respect to the Sun. Four approaches (or what, to humans, looked like approaches), happened between 2349 BC to 2193 BC and twice between 1492 BC and 1440 BC, at intervals of 52 and 50 years, three (or four) of which resulted in plasma contacts between Venus and Earth. [\[note 20\]](#)

Venus in 2349 and 2193 BC

An approach of Venus with Earth happened in 2349 BC. It had been waiting to happen for 700 years. As Venus passed between Earth and the Sun, the plasmaspheres of the two planets touched and merged, a sudden electric repulsive impulse from a distance of about 20,000,000 miles shoved Earth away from the Sun and a giant plasmoid electric arc traveled from Venus to Earth, followed by lesser plasmoids. The orbit of Earth enlarged by 5 percent. The Absu was severely disturbed and disappeared. The orbital period of Venus seemed to have remained almost the same.

Because of the spectacular nature of the event, we know a considerable amount about this. It includes the "flood of Noah," the flood of Yao in China, the fall of the Absu, the return of Jupiter from death, the appearance of the Pleiades, the placement of the southern stars, and the appearance of the Moon. There are retellings from Babylonian, Bible, Canaan, Chinese, Egyptian, Vedic, and Maya sources. The Gregorian equivalent calendar day for the event is noted in chapter 21, and can be verified from Olmec site alignments, discussed in the chapter "Olmec Alignments." The orbit of the Earth enlarged to 260 days (from 240 days). The Moon appeared as the Earth moved to a larger orbit. It is uncertain how long it took the Moon to regularize.

The electric contact with Venus in 2349 BC was the first of four such events during this era (I suspect). All can be dated (or at least, estimated) from the records of the first histories. The details are reported in chapter 20. For the last event (of 2193 BC) we have considerable climatic and historical evidence, but no spectacular tales. Akkad collapsed and the Old Kingdom of Egypt came to a sudden end. The Earth's orbit enlarged to 273 days. This last contact happened 156 years after 2349 BC, in 2193 BC -- three times 52 solar years. The 52-year interval, I should note, was only in effect during this period. At later times it was 47 and 50 years.

Venus in 1492 and 1440 BC

A second series of approaches between Venus and Earth started in the year 1492 BC, with the second some 50 years later in 1442 BC (originally thought to be 52 years, and 1440 BC). Venus, on an inner orbital path, aligned with the Earth and Sun. This approach was apparently much closer (about 10 million miles, 16 million km) than the previous contact of 800 years earlier (about 20 million miles, 32 million km). Following a massive compressive

impact in the Pacific Ocean below the equator by a few degrees at most, an arc from Venus to Earth was delivered laterally, traveling (perhaps) a number of times around the globe.

[\[note 21\]](#)

Genesis details two more contacts, one 6 days later, and one 6 weeks later. Even if these intervals were written to conform to a required completion before the Sabbatical seventh day or seventh week of the new era, it does not matter. It would, as I have pointed out, take about 6 days for the plasmasphere tail of Venus to pass by the plasmasphere of Earth.

The climatic and historical record of the events stands out clearly. The immediate effect of the circumferential arc was a cloud cover lasting decades, resulting from the arc traveling through the Pacific, Indian, Mediterranean, and Atlantic oceans. But more likely the cloud cover was due to the compressive force which landed in the Pacific Ocean, which was followed directly by a lifting force. And then an arc. The cloud cover is described in Genesis and in Mesoamerican records. The Israelites "walked in darkness" for 40 years; in Mexico "the people grew up in darkness."

I would blame this "darkness" on water vapor clouds, since the downturn was fairly short. This was unlike the longer climatic downturn of 2193 BC, which was due to nanometer-sized dust particles. Yet, the most drastic and permanent change was a severe decline in temperature. Much of this can be attributed to a radical change in the orbit of the Earth, a sudden jump from 273 days per year to 360 days, which moved Earth 30 percent further from the Sun.

Afterwards, Venus would frequently have been seen in the daytime skies, and perhaps periodically at close range ("close" being defined as 10,000,000 miles or so, 16,000,000 km). This is the image of the Goddess Isis or Inanna, generally benevolent but with a mean streak recalled from earlier encounters.

The Orbit of Mars

Mars did not escape from Saturn until after Saturn had receded some distance from the Sun. As established in Appendix A, "Chronology," Mars probably was released 80 years after 3147 BC, and thus was first seen in 3067 BC.

By that time the planets Jupiter and Saturn would already have relocated 50 or 100 million miles further away from the Sun. By the time Mars was released it would have started with an aphelion much further away from the Sun than Earth or Venus, probably at two AU, the edge of the asteroid belt.

The orbit of Mars overrode the orbit of Earth during the first 300 years after 3067 BC, and repeatedly crossed Earth's orbit close to Earth. Mars came close enough (with Mars beyond or above Earth), for Mars to make electric contact (via a plasma stream) to Earth -- recalled

from the text of spells on coffins and pyramids, and eventually recorded in the Egyptian *Book of the Dead*. The Egyptians understood this as Horus taking on the leadership of Egypt (similar interpretations obtain in Sumer).

Any dates at all would qualify for a contact between Earth and Mars, because Earth and Mars would not need to be in line with the Sun, unlike the condition of an electric field force between Earth and Venus.

But Earth and Mars would near each other only on rare occasions. In the 300-year period after 3067 BC this apparently happened at 30-year intervals -- the sequence of kings at Kish, pharaohs in Egypt, and the birth of first sons in the Bible all happen at various intervals of 25 to 35 years. Mars would appear close to Earth, possibly above the northern hemisphere, seen at first on the night side, then seen rotating around the sky, and finally entering the day skies (or the reverse of this). The movement and rotation of Mars is, of course, caused by the rotation of Earth. When close to Earth, a conical plasma connection was established between Earth and Mars -- from the Earth's ionosphere to the lower hemisphere of Mars. Because the edges of this cone were the most dense, it looked as if the "mountain" had distinct edges and flat sides, like a pyramid. Mars would lose its plasma connection with Earth as soon as some distance was achieved. Strange as the suggestion for this condition seems, it is the only explanation of the sudden start of building pyramids worldwide when Mars no longer appeared after about 2750 or 2700 BC.

This sequence of events probably lasted only a few days at the most. Then Mars was off again into deep space (or toward the Sun), repeating this performance approximately 30 years later. The event of sitting on a throne, with what looked like a race around the skies of Earth possibly established some elements of the "Sed festival" of the Egyptians, celebrated at 30-year intervals.

[Image: Rotation of second nodal point of an orbit (apsidal precession). Illustration after Wikipedia, public domain.]

We don't know when it stopped, but after about 300 years the Earth and Mars did not close in on each other again, at least, not until 1000 years later in 1900 BC, or 2000 years later in the 8th century BC.

It is likely that the elliptical orbits of Mars and Mercury rotated away from the orbit of Earth -- precessed away. It would take very little precession of the orbits to entirely remove any "close calls" and it would take a full rotation of the elliptical orbits to bring back the condition where Earth and Mars would again come close to each other.

If we go by Horus names taken by pharaohs, and the kings of Sumer with God status, it looks like the orbit of Mars fell completely away from the orbit of Earth after 2700 BC, for the references to God-like kings in the Mesopotamian *King List* cease at that time. By 2600 BC humans started to build mountains of chalk and pyramids of stone to invite a return of the God, something which happened worldwide. The constructions were an indication that the primary image had disappeared, and typically, the humans felt that it was up to them to induce the return of the God.

Using an Ephemeris

Throughout this text I have checked the heavens with an ephemeris program named "SkyGlobe 3.6," written by Mark Haney in the early 1990s and issued by KlassM SoftWare. It shows the Moon and planets, the ecliptic, and the constellations. It can be set for different geographic locations and different dates. As locations I mostly used Cairo, Baghdad (for Babylon), Beijing, and Mexico City. From my perspective, the program will be in error at dates earlier than 685 BC. More on that below.

SkyGlobe makes allowance for the precession of the equinox, skips the year zero, and switches from Gregorian to Julian in October of AD 1582 (based on Julian days). Correction from a Julian calendar to a backward extension of the Gregorian calendar can be

(approximately) accomplished by adding 1.5 days for every 400 years before AD 1582, starting with a 10 day difference. [\[note 22\]](#)

Locations on the dome of the stars are identified by elevation and azimuth, and Right Ascension. Right Ascension (in hours) is calculated from the spring equinox for the date being viewed, which is a drawback at times (even though it is the standard today). Because the motions of the planets are based on calculated approximation, there is some slippage in moving far into the remote past.

The program also allows seeing the Solar System in rotation from above. This feature is of great value in checking for locations and conjunctions of the planets as a function of time. Single keys will allow rotating the system in hours, days, months, etc.

As with any ephemeris calculations, some corrections have to be made. All the dates from before the Roman era should be corrected by four years for the error introduced in our reckoning by Dionysius Exiguus in AD 532. Thus for any known date in the Eastern Mediterranean, the ephemeris should be pointed to a date four years earlier -- further back in time (and on occasion, five years). An additional error of one year, for the passage from AD to BC, needs to be kept in mind. The SkyGlobe ephemeris program, however, properly skips the year zero between the eras, although this takes it out of phase with "astronomical" dates by one year.

Patten and Windsor write the following about Exiguus:

"Dionysius Exiguus was a medieval monk, who was given the task of resolving a calendar dispute as to the proper date for Easter. Later research revealed Dionysius had missed four years in assessing the year of Christ's birth. Many centuries before this error was identified, his dating system for history had come to be accepted."

"His error was not revised, in order to minimize confusion. By the time his error was realized, the sequencing of historical dates for the Roman Empire and for early Christianity had long ago become too widely accepted. So Dionysius's dates were kept, and mankind was left with a quixotic system. The accepted system cites that Christ was born in 4 B.C.E., seemingly an impossibility."

-- Donald W. Patten and Samuel R. Windsor *The Mars-Earth Wars* (1996).

The correction of 4 years applies to dates for the Eastern Mediterranean region, where all dates are tied to the Babylonian king list developed by Ptolemy, extending from 747 BC until the second century AD. It does not apply to dates from China where Western researchers of the 19th century have correctly converted dates to an absolute Western chronology. All celestial dates from China which I have inspected via an ephemeris were correct for the listed date.

I need to add one more caveat. An ephemeris program based on today's orbits cannot be correct for dates before the 7th century BC, for the orbits of Venus, Earth, Mars, and Mercury all changed in the eighth and seventh century. In addition the whole dome of the stars rotated some 15 degrees in 685 BC, in effect shifting the equinox by two weeks.

But it is unlikely that the changes in orbits in the 8th and 7th century BC would make any significant difference when it comes to using an ephemeris for slightly earlier dates. Conjunctions might be off by a few days at most. This is because most of the changes I have proposed involve orbital eccentricity, of which we know, admittedly, almost next to nothing. If a planet's orbit changes shape, the planet will slow down on the portion of the orbit further away from the Sun and speed up on the portion closer to the Sun. The net effect is that the period does not change.

This is not true for Mercury, which changed its orbit and period radically in 686 BC. Otherwise, the sky before 685 can be simulated by setting the ephemeris to about 2000 or 2300 BC.

For the changes in 685 BC we have little to go on except what we know about Venus from the Mesopotamian Tablets of Ammizaduga and the Maya canonical values of the appearances and disappearances of Venus (from the *Dresden Codex*). The Maya values (last recopied in AD 1200 from earlier sources of about AD 700) total to 584 days, as they do today, even though the appearances of Venus in the skies and its disappearance behind the Sun differ from today's values by as much as 40 days.

This suggests that the orbit of Earth or Venus would make a difference in the synodic period of Venus only if we insist that a change in the shape of the orbit would in effect constitute a new orbit. But the synodic period of 584 days of Venus remained the same before 685 BC as after, even if portions of the time of the appearances and disappearances of Venus in the skies changed considerably. This last relates to the changes in the eccentricity of the orbit of Venus, which has subsequently become nearly circular. The ratio of the synodic period of Venus to Earth in 670 BC is nearly the same as today (1.63, today it is 1.625).

The change in the Earth's orbit, which added 5 1/4 days to the year in 747 BC, is only a 1 1/2 percent change from a 360-day orbital period. Thus the ephemeris would be "off" by only approximately 1.5 degrees before 747 BC. Lastly, the relationship between the Earth and its Moon and the Sun is radial. A change in the shape or size of the orbit does not change eclipses of the Sun or Moon significantly.

What this means is that, first of all, an ephemeris can be used, with some caution (and if obvious adjustments are kept in mind), for the period before 685 BC or even before 747 BC, and it can probably be used back to 1492 BC. And, secondly, this also means that nothing will be proven from an ephemeris about changes in the Earth's orbit, its ellipticity, or the timing of the equinox, or from earlier records of eclipses of the Moon or the Sun.

The Eighth and Seventh Century

The orbits of Mars and Earth crossed, after 1492 BC, but differences in inclination of the orbits and the location of their respective aphelion kept the two planets apart most of the time. If nothing else, these interactions kept alive the images of the Gods and their incomprehensible activities. It would take a long time before the slow alterations in the orbits would bring Mars close enough to Earth to cause any damage.

That started to happen in the eight century BC. The details can be gleaned from a number of sources, including Mesoamerican annals, and Chinese records. There are a number of dates marked with celestial events during these two centuries, which are discussed below, including the following:

- -- 776 BC, the suspected date when Mars and Venus both show up on the day side of Earth, and are involved in a "ballgame" with the Moon or Mercury. The eastern Mediterranean understood this to be a race.
- -- 747 BC, the date of an Earth shock, a change in the orbit of Earth, and the start of "the era of Nabonassar."
- -- 686 BC, the date of a second Earth shock, due to Mercury.
- -- 685 BC, the nova event of Venus and Mercury, and a change in the aphelion of Earth, which moves the orbit away from Mars's orbit.

What I will do below is to present mostly ephemeris information for these events. All the other evidence is presented in detail on the narrative pages of the main text. All the dates shown below are on the Julian calendar.

The Ballgame of 776 BC

The date of the ballgame of 776 BC was inferred (by others) from the date of the first Olympic Games (772 BC). The question to be asked of an ephemeris program for the year of 776 BC is if Mars and Venus could simultaneously appear on the day side of Earth in 776 BC. [\[note 23\]](#)

Of course using an ephemeris based on today's orbits will place Mars outside of Earth's orbit. I will have to suggest the existence of eccentricities which no longer show today and assume that in actuality Mars crossed the orbit of Earth at an earlier time. Venus, still on an eccentric orbit, would come near Earth but remain inside the orbit of Earth. The only requirement for an ephemeris program is to show that Venus, Mars, and Earth might have been in (or near) inferior conjunction at some date during that year.

Earth, Mars, Venus conjunction of 776 BC

An inspection of the orbits of the planets between the years 800 BC to 700 BC show any number of these near conjunctions of Mars, Earth, and Venus during this period, at six and seven year intervals. The following endnote lists these, along with the angle between the three planets, as measured from the Sun.

Mars is at inferior conjunction in February of 776 BC (thus passing close to Earth), with Venus passing Earth (or certainly seen) at the same time on the day side. Between February 24th and 25th, the Moon passes by Venus in the day sky. [\[note 24\]](#)

Mars in the 8th Century

It seems that only after the simultaneous appearance of Venus and Mars inside the orbit of Earth in 776 BC -- which became the starting point for the Olympiads -- did Mars repeatedly start cruising close to Earth. (In the chapter "Destruction by Mars" I propose, however, that the contacts started in 806 BC.)

In the diagram above I have noted two possible locations where Mars might have made a near contact with Earth. This is based on the model developed by Patten and Windsor. It should be expected that these would be separated by years -- that is, after Mars made an approach at the location in the lower left quadrant of the diagram above, the following close approach would happen at the location in the upper left quadrant 15 years later.

747 BC, the First Earth Shock

Patten and Windsor, in *The Mars-Earth Wars* (1996), propose that the length of the year changed in 701 BC. Considering the extensive evidence of calendar changes following on 747 BC, I will hold with the date of 747 BC. The starting year 747 BC (-747) and the date of February 27 is used for the compilation of the "Era of Nabonassar" by Babylonian astronomers. [\[note 25\]](#)

Patten and Windsor, for reasons of the celestial mechanics of their model, suggest a close approach of Mars and Earth and a change in the length of the year in 701 BC, and place this at the time of a full Moon. In their model, Mars travels between Earth and the Moon on the night side, and disturbs both orbits. This scenario is demanded if only gravitational interaction is used to change the orbit of the Earth. My suggestion is that Mars traveled past Earth on the day side.

[Image: Mars in the 8th century BC; after Patten and Windsor. Similar to prior image. Mercury not shown.]

The year 747 BC can be inspected with an ephemeris program. It will be the first year for which an ephemeris program should be nearly correct. Mars is in inferior conjunction (on the assumption that its travel took it inside the Earth's orbit) on about mid-March of the year 748 BC, Julian (-747) (which is 8 days earlier on the Gregorian calendar, but not exactly on February 26th). March 2 or 3 is the day of a new Moon, the second new Moon after the winter solstice. [\[note 26\]](#)

"The present definition of the Chinese New Year, as the second New Moon after the Winter Solstice, dates from the inception of the T'ai-ch'u Era in 103 BC."

-- Kelley L. Ross (2004)

On this day (February 28th) of the Maya Long Count, the count of days since August 11, 3114 BC, reaches a "zero position" at Baktun 6, with all the other cycles at zero (6.0.0.0.0). A change in Baktun happens only at about 400 year intervals. Baktun 6 was reached on February 28, -747, Gregorian.

687 or 686 BC, the Second Earth Shock

The second Earth shock can also be searched for. This event was suspected to have happened in 686 BC (-686), on March 23. There have been suggestions that 701 BC should be used, but we have a parallel record from China, with the suggestion for a date of March 23. Mercury is the agent for the Earth shock of 686 BC.

What is certain about this event is that none of the numerous people, including Immanuel Velikovsky, who have attempted to establish the year and date have come up with anything conclusive. A perusal of *Worlds in Collision* (1950) and the unpublished manuscript "The Assyrian Conquest" (1978), will show that no agreement was ever reached. The only certain date is from two Chinese sources, and both equate to March 23, 686 BC (Julian). The confusion encountered by Velikovsky may simply be due to the mismatch of astronomical chronology for China and the chronology of the Eastern Mediterranean. The Chinese dates were retrocalculated in the 19th century, and are listed as astronomical dates. These dates should be numerically reduced by four years to match dates in the chronology of the Eastern Mediterranean.

The event itself can be established by accessing an ephemeris for the date of March 23, 686 BC. The year of 686 BC is correct. It is specifically noted by Legge in *The Ch'un Ts'ew and The Tso Chuen (The Spring and Autumn Annals* translated AD 1872). The other source is from the *Annals of the Bamboo Books*, and was calculated by Jean-Baptiste Biot in the 19th century as 687 BC and is correct if this date was meant to be in astronomical notation, in which case it is equal to 686 BC in Julian notation.

To further confuse the issue, all the researchers were looking for Mars as an agent. It turns out that it clearly is Mercury instead. Mercury was almost directly between the Sun and Earth on March 23, 686 BC (Julian). As expected, this only happens when the Earth's orbit crosses the equatorial plane of the Sun -- thus at or near the equinox, on March 29, Julian. On March 23 the Sun and Mercury are displaced 7 degrees in azimuth, but only 2 degrees in altitude.

Additionally, I should point out that the shock from Mercury happened a year before the dome of the stars shifted in 685 BC, so that at this time the Sun stood directly below the Pleiades (rather than at the beginning of Pisces). Polynesian myths deal with a rat God who chewed through the nets of the Pleiades. In the afternoon, Mars stood in the sky, below the altitude of the Sun and to the east. The Pleiades were high in the south sky, but could not be seen. Mars should be understood as being within the orbit of Earth at this portion of Mars's orbit. This places Mars much closer to the Sun in the sky as seen from Earth than an ephemeris program will show.

With the placement of these three planets (Venus is the third) all in the same quarter of the sky with the Sun, the American Plains Indian tale of the snaring of the Sun by Coyote, and

the rescue by a mouse, starts to make sense.

Certainly it would seem that a plasmasphere tail from Mercury extending 57 million miles (92 million km) to Earth is an uncommon anomaly for a small rocky planet, which, however, it was not: the appearance of Mercury as the Mouse God "Smintheus" in 686 BC suggests that it still had a plasmasphere tail at that time.

But Mercury may have been much closer. If, as North American Indians hold, Mercury blotted out the Sun, it would have been between a half million and one-quarter million miles from Earth to be the right size at the time it eclipsed the Sun. Mercury is about the size of the Moon. However, with an atmosphere and a coma in glow mode, it would have been much larger in diameter, and thus the distance between Earth and Mercury could have been much greater. At any rate, it would mean that Mercury's orbit was radically different at that time from today, as I have maintained in earlier text.

I should also point out that the "look of a mouse" has to be due to a visible tail pointing away from Mercury after it no longer blocked the Sun. This was seen in the sky by North American Indians as the Sun started to rise up in the sky again -- presumably on the same day and the same afternoon. The tail of the mouse would only show up as Mercury moved out of alignment with the Sun.

The shock felt by Earth was also experienced by Mercury. At a mass of only 1/20th that of Earth, the repulsive electric impulse would have bolted Mercury away from Earth, and displaced Mercury to the much smaller orbit. Today the orbit of Mercury falls entirely within the orbit of Venus, and has the greatest orbital eccentricity of any of the planets. The ephemeris program, which can reasonably (and cautiously) be used in era before 685 BC, might produce a considerable error for the orbit of Mercury. In fact, four days in this case.

Let me recap the drama. Mercury was headed, I presume, outward bound from perihelion closer to the Sun, when its plasmasphere intersected Earth's plasmasphere. The Sun, Mercury, and Earth all lined up. This lineup had been avoided for a long time. Although Mars crossed Earth's orbit at the level of Earth, and thus came within Earth's plasmasphere, I suspect Mercury had always passed above Earth, clearing it by perhaps 300,000 miles (483,000 km), the size of Earth's plasmasphere.

Mercury was whacked with a repulsive shock and shoved in the direction of the Sun. Since Mercury crossed Earth's orbit at the level of the Sun's equator, it may have been forced into a completely changed orbit -- with a zero inclination to the Sun's equator, which is its inclination today. Only the forward motion of its original orbit kept it from falling into the Sun. I have in the text detailed that this event probably constituted the burning tower remembered throughout the world. American Indians recall that prairies and plains also burned in the southwest. The Polynesians saw a rat. A few hours later Sennacherib's army met with disaster.

If we go by Mercury's present orbit, which at aphelion is 51,000,000 miles (82,000,000 km) from Earth, then it could be suggested that this was the separation when electric contact was made. Mercury not only shocked Earth, but also may have changed the Earth's orbit some small amount, reducing it to 365.24 days -- the current value. Since this should have shown up in the Mesoamerican Tzolkin calendar, but did not, it would seem that the change made to Earth's orbit was limited to changing the shape (the eccentricity) of the orbit. This would not change the orbital period.

The Caloris Basin of Mercury

At first, on seeing the Caloris Basin of Mercury, I wondered if in 686 BC Mercury might already have been standing still, that is, rotating the Sun like a moon, always showing the same face to the Sun, or at best rotating very slowly. Like almost all the satellites of the planets, its spin may have already been reduced to synchronous rotation about the parent planet, in this case, the Sun. Today Venus has achieved that status also. The Earth is slowing its spin at a rate of one second per year, and will be the next to come to a standstill.

[Image: Caloris Basin, on Mercury. After JPL, 1975.]

I then realized that the Caloris Basin is located at the equator of the planet. As I mentioned earlier, a shock to the equator only shoves a planet over in space. This is motion "in translation" and thus there is no gyroscopic reaction torque induced, and no corrective motion is started. So the impact mark would be circular, and not have the typical leading and lagging edge markings that impact marks on Earth have.

The Caloris Basin of Mercury is located at the equator and occupies somewhat over 30 percent of Mercury's diameter. Thought to be 800 miles (1,300 km) in diameter in 1975, it was measured at 963 miles (1,550 km) in January, 2008. Caloris is mostly a flat plain with what looks like circular lava fields. Caloris is additionally ringed with circular sets of mountains, and there is an antipodal location where the shock waves converged to break up the crust.

If this is the mark of a collision with an asteroid, then it is the largest impact crater in the Solar System. If this had been due to an asteroid, the impact should have obliterated Mercury and removed the fragments entirely from the Solar System. If it was caused by electric force between Mercury and Earth in 686 BC, then the marked circles seem almost too small.

In addition to the fact that the surface of Mercury falls away rapidly from the center of the impact, thus causing only sliding damage at the periphery (mountains), the electric field at Mercury would have been radial, and thus similarly would fall away from the center. At the edges of the basin only a shoving movement of the crust would have been experienced.

A year later, in 685 BC, the Sun went into high activity, and Venus and Mercury blazed like suns. Every surface feature of Mercury was overlaid with cathode burn marks -- or "meteor impacts" as astronomers call them.

Endnotes

Note 1 --

A frequency plot of orbital inclinations (see below), which hides the information of the ten gaps where there are no asteroids, suggests that five planets may have been destroyed. The plot seems to consist of five superimposed Gaussian distributions. A distribution of orbital inclination is the most likely graphical representation which would more or less preserve the original *in-situ* locations of the parent bodies. Considering the sparsity of objects in the asteroid belt, I feel comfortable in plotting these Gaussian distributions on top of each other.

[Image: "Histogram of the orbital inclination of objects in the asteroid belt." (Data: <ftp.lowell.edu/pub/elgb/astorb.html>. Plotted at case.edu/sjr16/) Additional graphics added.]

Tom Van Flandern has suggested that the meteorites fallen to Earth (constituting a sample of the contents of the Asteroid belt) represent at least 3 or 4 planets.

Note the extent of the orbital inclinations. Planetary orbits vary only seven degrees from the ecliptic. The *mode* of the distribution of the asteroids is about 4 degrees, the *mean* is about 8 degrees. There are secondary peaks at 9, 12, and 23 degrees. It is, at any rate, not a single Gaussian distribution.

Note 2 --

[Image: Asteroid distribution with distance from the Sun in AUs. After Zdenek Kopal "The Realm of the Terrestrial Planets" (1979).]

Another graph of the distribution of asteroids, above, based on some 4000 objects known by 1950. Please note that the vertical axis is not linear. This exaggerates the asteroids closer to Mars. The horizontal axis shows the number of known objects at the respective location. The gaps can be clearly seen. [\[return to text\]](#)

Note 3 --

The resonances may be calculated from Kepler's third law which defines the relationship between the period of an orbit and the radius of an orbit, as follows:

$$(T_{\text{Asteroid}} / T_{\text{Jupiter}})^2 = (r_{\text{Asteroid}} / r_{\text{Jupiter}})^3$$

The asteroid belt period, as a fraction of multiples of the period of Jupiter is found by using 1 for the period of Jupiter and unit AUs for the orbital radiuses:

$$T\{\text{Asteroid}\} = \sqrt{(r\{\text{Asteroid}\} / r\{\text{Jupiter}\})^3}.$$

orbital resonances for various locations of Jupiter								
approx asteroid orbit [AU]	0.50 AU orbit	0.70 AU orbit	0.90 AU orbit	1.10 AU orbit	1.30 AU orbit	1.50 AU orbit	1.70 AU orbit	1.90 AU orbit

Note 4 --

That Earth was not kicked out of the domain of Solar System remains somewhat of a mystery. All life on Earth would have come to an end. In addition to suggesting that the Earth was simply locked out of the reformed plasmaspheres when Saturn and Jupiter met, we could also follow Tom Van Flandern, who makes the claim, in *Dark Matter, Missing Planets and New Comets* (1999), for a "sphere of gravitational influence" for planets and objects in space, which under normal circumstances extends to about 100 planet diameters from the primary. Objects which are within this sphere (and which do not exceed escape velocity with respect to their primary) will remain (and travel) with the primary. Garbage jettisoned from space ships reacts this way, it just floats along with the ships. A number of conditions are able to change and negate this; the primary condition being the presence of another nearby large mass.

The point of release of Earth would constitute the aphelion of its (new) orbit around the Sun - the location furthest away from the Sun.

[\[return to text\]](#)

Note 5 --

See the Appendix "Change in the Axis" for notes on Dodwell's 25.2 degree inclination. See the Chapter "The Popol Vuh" for additional discussion on the Blowgunner Pot.

[\[return to text\]](#)

Note 6 --

The separation distances are from the tangent of the differences in the angles, multiplied by the assumed distance to the Sun, where the tangent is defined as $\sin () / \cos ()$:

$$\text{vertical distance} = 0.7 * \text{AU} * \sin (\text{angle}) / \cos (\text{angle}),$$

Here we are using 0.7 AU as the location and 93 million miles for one AU. To obtain the distance, for example, between Uranus and Saturn:

$$0.7 * \text{AU} * \sin (2.49-0.77) / \cos (2.49-0.77) = 1,954,865 \text{ [mi]} (3,146,000 \text{ km})$$

Adding 10 million miles to 0.7*AU makes little difference in the vertical separation distances, as I have mentioned earlier. The reader will also note that the calculations include a shortcut in that it is assumed that the repulsive forces are directed on a radius line from the Sun, instead of being directed from Jupiter. This also will make almost no difference.

[\[return to text\]](#)

Note 7 --

I have not done the calculations for an exchange of KE (kinetic energy) involved, or for an exchange of momentum. Electric energy could be at cause also, and there are some hints from recent measurements, as follows: Since 1973 it has been repeatedly noticed that whenever Earth experiences a massive coronal mass ejection from the Sun, the Earth's rotation suddenly decreases, although only by nanoseconds. The speed of rotation increases again over the following few days, at a slower rate than the initial decrease in rotational speed, and returns to normal.

The process of slowing down and regaining speed thus seems to result from a sudden change in the coulomb charge of Earth (intercepting solar protons), followed by a reduction of the surplus charge over the following days through the normal leakage out to space away from the Sun along the Earth's plasmasphere tail.

The spin of the Earth is decreasing currently. The international atomic clock, which determines the length of the day for Earth, has been adjusted by thirty seconds since 1972. The Earth's rate of rotation thus has slowed 30 seconds in 32 years -- about a second per year. This is certainly much more than the nanosecond deviations experienced with the occasional coronal mass ejection. Extrapolating one second per year to the time since 3147 BC, results in a calculated loss of 1.4 hours. Although this represents an extreme and probably illegitimate extension of the data, it confirms my supposition that Earth (and also Mars) today spin at the same rate, or nearly the same rate, as before the breakup of 3147 BC, and also suggests that Earth and Mars both rotated at about 24 hours per day before 3147 BC. The average orbital distance from the Sun for Earth and Mars has not changed all that much.

Tim Thompson contests this as a young-earth-creationist argument (<http://www.tim-thompson.com/young-earth.html>), although I have no idea what he is talking about.

In the last 25 years, Saturn has changed its rotational period from 10 hours and 39.3 minutes (1982) to 10 hours and 45.5 minutes (2004) -- about six minutes, or an average of 17 seconds

per year. This data is based not on the rotation of its cloud cover, but on the rotation of its magnetic field. This is an astoundingly large amount, and difficult to comprehend and explain in astrophysical terms.

[\[return to text\]](#)

Note 8 --

I am at a loss to explain how the inclination of Mercury's orbit could have changed in 686 BC.

[\[return to text\]](#)

Note 9 --

The White (and Red Crown) of Egypt depict Mars in the stream of a plasma connection in glow mode from Saturn, probably at a late date in the "Era of the Gods" -- after Saturn had ceased its initial nova condition in arc mode. The White Crown shows the plasma stream frontally lighted by the Sun and thus hiding Mars. The Red Crown shows the same stream at night, back lighted by the Sun (and casting a partial shadow) with the red surface of Mars showing through the plasma stream.

If we assume that the White or Red Crown of Egypt represents approximately the size of a human head and seen at arm's length (which is, of course, very subjective), then it might have subtended about 2.5 to 3.0 degrees (the angle subtended by a hand at arm's length).

On the basis of the above conjecture, it could be suggested that the upper bulb of the White Crown, representing Saturn, would be about 1.5 degrees wide visually (half the width of the larger Horus bulb). That clearly places Saturn 2.8 million miles (4.5 million km) from Earth.

$$72000 * (\cos (1.5) / \sin (1.5)) = 2.75 \text{ million miles}$$

The same reasoning, applied to Mars in its lowered position, reveals a distance of about 80,000 miles (129,000 km) between Earth and Mars at the closest approach:

$$\arctangent (4200/80000) = 3.0 \text{ degrees.}$$

[\[return to text\]](#)

Note 10 --

At two AU the distance would amount to...

$$2 * \text{au} * \sin (2.49-1.85) / \cos (2.49-1.85) = 2.1 \text{ million miles (3.4 million km).}$$

Mars would have been much closer to Earth. This might, in fact, be suggested from the *King List*, where the last descent to Earth of Mars was only 80 years prior to 3147 BC, half of the average of 141 years of the previous seven "reign lengths."

[\[return to text\]](#)

Note 11 --

Electrons in the Van Allen belts of the Earth, a toroidal ring of plasma a few hundred miles to a thousand miles above the equatorial regions, will move to different locations over distances of a thousand miles in only a few seconds when a lightning strike is experienced far below in the atmosphere of the Earth (the last few miles above the surface). We could expect the same rapid reconfiguration when two planetary plasmaspheres intersect. A thousand miles in two seconds ("a few") represents a speed on the order of 2 million miles per hour. This is actually equal to the speed of the Solar Wind in the region of space near Earth today.

Mars and Mercury may have remained within the plasmasphere of Saturn after 3147 BC because Mars, having been in periodic violent discharge from Saturn at least since the Gravettian, 40,000 years ago, must have been at a potential partially equal to that of Saturn. I can also place Mercury in the polar configuration late in the Gravettian (circa 24,000 ya) or in the Magdalenian (17,000 to 14,000 ya), but certainly long ago.

The plasmasphere which reformed around Saturn would have no cause to exclude Mars from its enclosing bubble. Only on arriving at the asteroid belt, would the plasmasphere of Saturn have radically reconfigured itself to match conditions of the conducting dust and rocks nearby, resulting in the exclusion of Mars and Mercury from Saturn's electric influence.

This scenario seems reasonable in accounting for the release of Mars (and Mercury) 80 years after 3147 BC, as well as accounting for the swarm of dust and asteroids which accompanied Mars for the next 3000 years. It would mean that Mars's initial orbit (as also for Mercury) was very elliptical, with aphelion beyond the initial edge of the asteroid belt. The scenario proposed by Patten and Windsor also suggests aphelion within the asteroid belt.

[\[return to text\]](#)

Note 12 --

The raven might have been Saturn, with its rings as wings. But I doubt it.

[\[return to text\]](#)

Note 13 --

There are other "births" in Greek mythology. One records the birth of a God (planet) from Zeus's thigh -- thus the planet was first noticed as it appeared from behind the lower mountain shaped coma. This likely is the image of the mummy of Osiris with his erect penis. In Greek mythology the erect penis will turn out to be Dionysus. Dionysus belongs to the class of Gods who are "twice born" -- where the second birth for Mercury happens in the seventh century BC. In this case the second birth is the fiery appearance in 685 BC as if Venus gave birth to Mercury.

[\[return to text\]](#)

Note 14 --

The reader should take this statement as an admission that, first, we know only a little of the interactions of plasmaspheres, and second, that the effects are neither as clear-cut nor as discrete as presented here.

[\[return to text\]](#)

Note 15 --

I initially placed the event of 2349 BC in Central Asia. A map inspection reveals two semicircular configurations of mountains, both with the open (flat) side pointing north or northeast. One is identified at the lower edge by the rim of mountains of the Himalayas, with Tibet as the flat area of the basin. The Tibetan plateau is known to be of "recent" origin. In fact, it is held today by geologists that both the "uplift" of the Himalayas and the Tibetan plateau are as recent as "after the end of the last ice age," thus more recent than 14,000 years ago. This largely argues against the plate tectonics notion of the Indian subcontinent colliding with Asia some sixty million (60,000,000) years ago, although the current Himalayas do constitute the raising of a previous set of more modest mountains.

The other large impact basin is further north, with Lake Baikal included in the curvature. I would suggest that this might be the impact of 2193 BC. Since we are aware of a long period of reduced light (reduced agricultural production) starting in 2193 BC, this seems like a most likely location which would provide a path for a continental lightning strike and extensive forest fires.

Since the lightning strikes in 2349 BC were plasmoids which apparently dissipated at the equatorial rings or the ionosphere, there might have been few forest fires at that time.

I should point to an article by Donald W. Patten and Samuel R. Windsor, "Catastrophic Theory of Mountain Uplifts" in *Catastrophism and Ancient History* (1991), which assigns the uplift of the Himalayas and other mountain ranges to close passes of Mars in the 8th century BC. I'll reluctantly assent to some mountain ranges, but not the Himalayas (nor the Andes), since the overall structure of these mountains and the adjacent areas do not easily conform to the geological mechanics envisioned by Patten and Windsor.

The Indian bar-headed goose (*Anser indicus*) flies over the Himalayas to nest at the Tibetan Plateau and in Mongolia. There are no low passes through the Himalayas. The geese regularly fly at 20,000 feet.

[\[return to text\]](#)

Note 16 --

The Earth as a gyroscope is not equivalent to a toy top set on a table, and does not react the same way to an impulse. (An "impulse" is the momentary application of a force.) There is absolutely no comparison between a toy top or toy gyroscope and a sphere spinning in space without any support.

The top set on a table is subject to a "normal force" directed up from the bottom, and the force of gravity directed down along the same axis. As it is nudged, the force acting through its center of gravity is offset from the point of contact at the bottom. This constitutes a "couple" (a torque) acting permanently around the horizontal center of the top. The reaction torque resulting from this will set the top into precession. And it will be permanent, for the leaning of the top is permanent. Nudge it more and it will turn upside down instead. The top will do this when the force of sliding friction (about 20 percent of the normal force) has been overcome.

Until a top is removed away from the effect of gravity, and off the table, it will not act like Earth under the influence of an impulse. The notion of the Earth turning upside down -- expressed repeatedly by Velikovskian researchers and savants who apparently have never taken elementary physics or mechanics in high school -- is based on false analogies. I cannot believe that some of these articles were ever printed in the Velikovskian journals.

[\[return to text\]](#)

Note 17 --

Because the contact in 2349 BC happened at the fall equinox, it is amenable to a simple analysis. At the fall equinox the axis of the Earth was tilted 30 degrees "forward" along the orbit. The center of impact may be estimated to be about 40 degrees north of the equator. The hit occurred when the impact point faced the Sun. Thus the impact was not directed through the center of Earth, but on a line 30 degrees above the center and through the Earth. Thus the first reaction was a tilt of the Earth to the northeast.

The gyroscopic reaction would immediately change to a movement of the Earth's axis away from the first tilt. The two motions would describe a counterclockwise circle of the Earth's axis as seen from above. This moved the exterior force geographically toward the southwest.

[\[return to text\]](#)

Note 18 --

I suspect that the orbital period of Venus might have been on the order of 240 days initially, when the Earth's period was also 240 days. With the eccentricity of Venus at 0.15 and the eccentricity of the Earth at 0.10, the orbit of Venus would certainly have overrun the orbit of Earth.

[\[return to text\]](#)

Note 19 --

The Moon's orbit, which describes a cycloidal pattern at the same distance from the Sun as the Earth, but at a slightly different orbital inclination, precesses in only 19 years to repeat its positions with respect to Earth and the background stars.

[\[return to text\]](#)

Note 20 --

I should note that only for far distant interactions would two planets have to line up with the Sun, for the Sun's electric shadow of the inner planet determines the location of the planet's plasmasphere tail. But planets could interact electrically at much closer distances if two plasmaspheres brushed against each other in passing. This apparently happened with Mars and Earth for 300 years starting in 3067 BC, again for a period after 1935 BC, and the last time in 806 to 687 BC.

In 776 BC Venus seems to have made electric contact with Mars but not with Earth. Note that the number of closely spaced approaches seems to have decreased over time, as did the severity of the electric contacts.

[\[return to text\]](#)

Note 21 --

I had originally (years ago) only considered gravitational interaction for the displacement of the Earth's orbit in 1492 BC, and thus had Venus pass on the night side of Earth. Velikovsky, however, suggests that Venus passed on the day side of Earth, based on textual evidence. This is an interesting concession, since it would discount gravitational interactions altogether.

Velikovsky hoped that magnetic interactions would do the job. That is doubtful. But it works even better if electric interactions are considered. The interaction would have to be during daylight, at about noon, and near the equinox. If we allow for the repulsive forces of the electric fields, which would become "visible" to the two planets during a plasmasphere contact, then the Earth would be "shoved" to a larger orbit instead of being gravitationally or magnetically "pulled."

[\[return to text\]](#)

Note 22 --

Greater accuracy is achieved with the use of a public domain calendar conversion program written by John Walker, which allows conversion between the Maya Long Count (with the Tzolkin and Haab days) and the Julian calendar and Gregorian calendar. I use a modified version which allows use of either the August 11 or the August 13 correlation.

The advantage of the backward-extended Gregorian calendar is that it represents solar years, although the days of the year will be out of phase with reality. The Julian calendar, based on Julian days, diverges progressively from solar years.

[\[return to text\]](#)

Note 23 --

Additional data brought to bear on this event by Velikovsky was a "reference to some celestial event of 776 BC" from a secondary source referring to the *Shih King* (the Confucian *Book of Odes*). However, the *Book of Odes* lists only an eclipse of the Sun. As a book of collected poetry the *Shih King* is not really concerned with celestial events.

James Legge translates the passage of the *Shih King* as:

"At the conjunction (of the Sun and Moon) in the tenth month, on the first day of the Moon, which was Hsin-mão, the Sun was eclipsed."

Legge further notes:

"This eclipse is verified by calculation as having taken place in B.C. 776, on August 29th, the very day and month assigned to it in the poem."

It is only curious that this is the only "celestial event" which is listed in a book of poetry, and it may be a coincidence that this is in the same year as the event of the ballgame.

By my retrocalculation the eclipse happens in the late afternoon on September 6th, 776 BC, on the Julian calendar, which is astronomical year -776 for the ephemeris program I am using, and August 29, -775, on the Gregorian calendar, matching Legge's date quoted above as "B.C. 776, on August 29th." Of course both my ephemeris program and the savants of the late 19th century are using the same assumptions about the constancy of the Solar System. But I do not think this was simply a solar eclipse by the Moon, for the date is 30 years before 747 BC, and thirty years before the Moon's orbit reduced enough to actually cause eclipses to be seen on Earth.

The *Encyclopaedia Britannica* reports:

"A date of 776 BC was formerly adopted for such an event, but modern computations show that no solar eclipse in that year was visible in China. A revised date of 735 BC has been proposed."

I disagree. A solar eclipse was certainly visible in Peking on the date above, although perhaps in the late afternoon. The *Encyclopaedia Britannica* may also have reference to a reading of the first stanza stating that the eclipse of the Sun followed an earlier lunar eclipse. An earlier lunar eclipse would have been 14 or 15 days earlier, at night. On August 22 (Julian) at 1:45 AM -- not on September 6th -- the Moon is on the ecliptic (in line with the Earth and the Sun) and 12 hours removed from the location of the Sun. That defines a lunar eclipse. The *Encyclopaedia Britannica* continues with:

"Throughout the subsequent thousand years or so, lunar eclipses were hardly ever reported in China -- in marked contrast to solar obscurations, which were systematically observed."

What Velikovsky failed to note from his secondary source, is that in the third stanza of the ode mention is made of lightning and geological disturbances, including the lifting of streams and valleys.

*Grandly flashes the lightning of the thunder.
There is a want of rest, a want of good.
The streams all bubble up and overflow.
The crags on the hill-tops fall down.
High banks become valleys; Deep valleys become hills.
Alas for the men of this time!
How does (the king) not stop these things?*

I find it very interesting that the "solar eclipse" is associated with catastrophes. I would assign the movement of hills and river and the lightning strikes to a close passage of Mars, but the year 776 BC in China, based on astronomical data, does not match the year 776 BC in the Eastern Mediterranean, based on chronological data. It is off by four years, which actually may not be a problem, since the first Olympic Games could have started either 4 or 8 years after the event.

It should also be realized that texts in China, dating from the seventh century BC, were often corrected, even as late as AD 900 or AD 1000. Others have suggested this, and I have noted this for the entry concerning the calendar adopted by Yao as described in the *Annals of Shu*. It is possible that the lunar eclipse followed by a solar eclipse were retrocalculated at a late date and inserted to account for the disturbances noted in the poem. Additionally, I believe that no lunar or solar eclipses were experienced anywhere (except perhaps in the tropics) before 747 BC. This was Mars.

[\[return to text\]](#)

Note 24 --

The following lists the coincidental inferior conjunctions of Mars and Venus with Earth, between 800 BC and 700 BC. The angles listed are measured from the Sun, and are taken from printouts of visual best approximations of "close passes" of Venus and Mars.

*[Image: Mars, Earth, Venus on February 17, 776 BC;
Mars shown within Earth's orbit.]*

year*	angle	interval
800	17 deg	6
793	11	7
787	24	6
780	10	7 <-- 776 BC
774	26	6
768	21	6
761	15	7
755	28	6
748	20	7
744	28	4
736	28	8
729	25	7
716	22	13
712	20	4

* corrected by 4 years

The corrected date corresponding to 776 BC is marked. I have excluded conjunctions of 30 degrees or more, some of which happen at odd intervals of two, four, or five years. The date of February 25 -780 Julian is February 17 -779 Gregorian, and equal to the year 776 BC in Eastern Mediterranean chronology.

[\[return to text\]](#)

Note 25 --

Velikovsky mentions, in the unpublished "The Assyrian Conquest":

"It is often asserted that the Era of Nabonassar was Ptolemy's invention; but it is a fact that one of the most important of the Babylonian historical texts, the so-called 'Babylonian Chronicle' (B.M. 92502), starts with the reign of Nabonassar, or the year -747. See H. Winckler and J. N. Strassmeier, Zeitschrift für Assyriologie, II (1887), pp. 163-168. Cf. D. J. Wiseman, 'Chronicles of Chaldean Kings' (London, 1956), pp. 1-2."

-- Immanuel Velikovsky, from "Haremhab's Contemporaries" at [\[www.varchive.org\]](http://www.varchive.org)

[\[return to text\]](#)

Note 26 --

Velikovsky quotes from J. de Costa, *The Natural and Moral History of the Indies* (1604), that the new year among the Indians of Mexico started on February 26th (supposedly on the Julian calendar, but this is on the Gregorian calendar).

From another secondary source I have information attributed to Bernadino de Sahaguán, in *Historya General de Nueva España* (circa AD 1530) who identified the start of the Aztec year with February 12 (supposedly) on the Gregorian calendar. However, February 12 falls on the Julian calendar, and is equivalent to February 22 on the Gregorian calendar (of the same year). February 22 is five days before February 26. February 22 is here thus the end of the year, with the five extra days following.

it is primarily data, and well worth skipping.
No metric equivalents in this Appendix.

Site Alignments

The following data is the results of an initial investigation. The latitudes and longitudes are from www.geonames.org. They are shown as **{degrees north latitude} -- {degrees west longitude}**. Truncation by Geonames. Locations of ceremonial centers and mountains are shown as "center:" and "marker:" below.

The angle between a site and a mountain can be found from the arctangent, **arctangent({difference in latitude} / {difference in longitude})**. These are shown below. If the latitude and longitude of the site is used as the first term of the differences, then negative angles denote "north of east" and "south of west."

The dates for various angles to the setting or rising Sun at the horizon are from a javascript program, saturniancosmology.org/sun.html, available locally, which can be set for different axial inclinations and latitudes. The angles shown are for sunrise, even if listed for sunsets. Sunsets will differ from sunrise by about 0.25 degrees in the part of the year closer to the equinoxes, with a virtually imperceptible difference as the Sun nears the solstices. Documentation of "sun.html" in the following endnote. [\[note 1\]](#)

The distance between two locations can be found approximately from the latitudes and longitudes also, using the Pythagorean theorem, and using 69 miles per degree of latitude and, for central Mexico at 20 degrees latitude, an average of 65 miles per degree of longitude, as **$\text{sqrt}((69 * \{\text{delta latitude}\})^2 + (65 * \{\text{delta longitude}\})^2)$** . Distance

between a center and a mountain is shown as "**remove:**" below.

[Image: sun.html output example. Kees Cook.]

[Image: Antipodal alignment example; plan view.]

The **line of sight distance** of a mountain can be found from $\sqrt{2 * 4000 * h}$, where "h" is the height in miles. The value of h is derived from $3.25 * H / 5280$, where H is the height in meters. The figure "4000" is the radius of the Earth in miles. The figure "3.25" is the number of feet per meter. Line of sight distance between a center and a mountain is shown as "**viewed:**" below. The line of sight is for sea level. Intervening hills and raised terrain might block the view. [\[note 2\]](#)

I am using the term **antipodal** to mean a reverse alignment to a horizon location. The

equivalence of angles above and below the east-west cardinal direction could be implied, and would be correct as equivalent, but makes little sense. At a few locations this is used, however.

Expected Dates

To ease the task of reading the following data, let me propose the important dates (horizon locations) which we are looking for (or which have been discovered inadvertently). The angles shown below are for a sunrise or sunset, and thus so many degrees north or south of an east-west axis. The angles shown in the list below are for an "average" latitude of 19 degrees. The actual angles will vary with the latitude of individual sites. These are shown for an axial inclination of 30 degrees and 23.5 degrees, since many sites use either the horizon location for a 30-degree axis or for a 23.5-degree axis, irrespective of what the current axial inclination was at the time the site was founded. The overhead (zenithal) passage of the Sun is also listed below. The dates are all "equivalent Gregorian."

Sunset in Degrees North of West for Various Dates		
For an axial inclination of ...	30 degrees	23.5 degrees
End of era 3114 BC, August 12	19.9 degrees	14.9 degrees
End of era 2349 BC, September 8	6.6 degrees	5.2 degrees
End of era 1492 BC, April 19	15.3 degrees	12.0 degrees
End of era 747 BC, February 28	11.0 degrees	8.6 degrees
Solstice before 685 BC	32.0 degrees	25.0 degrees
Plasmoid start, July 9, 685 BC	30.4 degrees	23.7 degrees
Jupiter plasmoid, July 14	29.4 degrees	23.0 degrees
Delivery of plasmoid, July 26	26.6 degrees	20.7 degrees
Zenithal, August 9 - 14	20.3 degrees *	
July 23 - Aug 1		20.3 degrees *
* varies with latitude		

In addition to sunsets, the setting angles for the Pleiades after culmination are suggested for some recurring alignment angles, as follows. These are additional to sunset alignments indicating the end of the era in 2349 BC on September 8. These are discussed in the text of the chapter "Olmec Alignments."

- Culmination 685 BC, Oct 8 Gregorian -- 13.0 degrees
- Culmination 600 BC, Oct 10 Gregorian -- 13.6 degrees
- Culmination 200 BC, Oct 14 Gregorian -- 15.8 degrees
- Culmination AD 100, Oct 18 Gregorian -- 17.1 degrees
- Culmination AD 200, Oct 20 Gregorian -- 18.1 degrees
- Culmination AD 400, Oct 21 Gregorian -- 18.7 degrees

The angle of 13 to 14 degrees and the angle of 18 to 19 degrees, correspond to the setting locations for the Pleiades at the dates shown above. These show up repeatedly.

I have added **Volcan de Agua** in Guatemala which is 3760 meters high, and can clearly be seen from **Izapa**. **Izapa** is located at the base of the volcano **Tacana**. But the site axis (16 degrees e of n, thus 74 degrees n of e) does not point to **Tacana** (69.67 degrees n of e) except as "sort of."

Additionally I have added an alignment corresponding to a site axis which falls 16 degrees east of north. At right angles this points to 16 degrees north of west.

```
Izapa (Chiapas), 14.90 -- 92.18

marker: Volcan Tajumulco, 15.034 -- 91.903, 4220 meter
remove: sqrt((69*(14.9-15.034))^2+(65*(92.18-91.9))^2) = 20.4 mi
a((14.90-15.034)/(92.18-91.9))/rad = -25.57 degrees n of e

marker: Volcan Tacana (Mexico), 15.116 -- 92.1
a((14.90-15.116)/(92.18-92.1))/rad = -69.67 degrees (out of limits)

marker: Volcan de Agua (Guatemala), 14.466 -- 90.742, 5280 meters
remove: sqrt((69*(14.9-14.466))^2+(65*(92.18-90.742))^2) = 98 mi
viewed: sqrt(2*4000*(3.25*3760)/5280) = 136 mi
a((14.90-14.466)/(92.18-90.742))/rad = 16.79 degrees s of e

marker: site axis, 16 degrees e of n
At right angle this equals 16 degrees n of w

Note: "a" is the arctangent, here and in following tables
```

[Image: Izapa alignments; plan view.]

The Sun passes overhead on August 11 (89.87 degrees above the horizon), rising at 15.55 degrees north of east. Malmstrom uses a latitude of 14.8 degrees north. This results in an alignment corresponding to August 12, where I have August 11.

The alignment at right angles to the site axis points also to a sunset on August 11, at 16.0 degrees (15.56 n of w).

There is no solstitial alignment. The volcano **Tajumulco** is held to represent a solstitial alignment by Malmstrom (and others), but an alignment of 25.57 degrees n of e, is not close to the solstice sunrise which happens at 24.36 degrees n of e. It is off by more than a degree, which at the time of a solstice, causes an error of 15 days.

I should note, however, that there is no reliable latitude and longitude for Izapa, and changes of a few percent will change the angles to some of the nearby mountains considerably. Malmstrom used a latitude of 14.8 which is seven miles south of my use of 14.9 degrees.

Edzna

center: Edzna (Campeche), 19.583 -- 90.25

The long axis of the site is aligned 15.5 degrees east of north.

The Sun passes over the site on July 25th.

[Image: Edzna alignments; plan view.]

The 15.5-degree alignment is identical to the alignment of the long axis of Teotihuacan in the valley of Mexico and results in sight line between three structures at a right angle to this, which represents a sunset on August 12, 3114 BC (15.6 degrees north of west).

The overhead passage of the Sun is elevated at an angle of 89.96 degrees on July 25th, setting at 20.85 degrees n of w. New Year's Day is July 26th.

Malmstrom lists an additional sightline made at 30 degrees north of west. He identifies this as the most northerly displacement of the Moon. This is correct, for at an "axial inclination" of 23.5 degrees for the Earth plus 5 degrees more for the Moon, this places the angle to a possible horizon location of the Moon at 30.42 degrees n of w.

San Lorenzo Tenochtitlan

San Lorenzo is an extensive site. I have checked data using the latitude/longitude for three included sites, shown below, but am only showing the results for the village of **Tenochtitlan** which seems to strike an average.

The first three sites are within 8.3 miles of each other; **Potrero Nuevo** is 10 miles further south. **Tenochtitlan** is a couple of miles north of the archaeological site, thus about 0.03 degrees of latitude different. The following only considers the location of **Tenochtitlan**.

[Image: San Lorenzo alignments; plan view.]

San Lorenzo site identity:

18.177 degrees n of w -- At 5452 meters, **Popocatepetl** is the 2nd highest mountain in Mexico, but cannot be seen from **San Lorenzo**, since it is 267 miles away. Under the condition of a 30-degree axial inclination of the polar axis, this mountain would signal the day (sunset) that the Sun passes directly overhead at **San Lorenzo (Tenochtitlan)** on August 15 (setting at 18.45 degrees n of w).

After 685 BC, the Sun would pass directly over **San Lorenzo** on August 2, 13 days earlier, setting at 18.54 degrees north of west. The horizon location thus stayed nearly the same.

San Lorenzo era marker:

15.05 degrees s of e -- **El Chichon** is 1060 meters high. This mountain could not be seen. Before 685, with the Earth's axis at 30 degrees, this angle defined a sunrise in winter (sunrise at 15.23 degrees south of east), but in an antipodal direction it is a spring sunset on April 19th, the start of the era after 1492 BC.

15.36 degrees s of w -- At 3396 meters **Cerro Zempoaltepec** is the 11th highest mountain in Mexico. It can be seen from any of the **San Lorenzo** locations. With the Earth's axis at 30 degrees, the angle defined a winter sunset. In the antipodal direction it marked a spring sunrise, which matches the sunrise angle made by **El Chichon**, April 19.

Under the condition of having the axis of the Earth was at 30 degrees, the mountains **El Chichon** and **Cerro Zempoaltepec** would triangulate **San Lorenzo** to a Gregorian equivalent calendar date of April 19th (15.23 degrees).

San Lorenzo additional notes:

The two alignments of 15 degrees could be suggested to represent alignments for a sunrise and sunset for August 12 in the current era. That is just unlikely.

```

[Image: La Venta alignments; plan view.]

La Venta site identity:

19.35 degrees north of west -- The alignment with **Volcan San Martin Tuxtla** defines the sunset after the overhead passage of the Sun at **La Venta** on August 14 (18.93 degrees), when the axial inclination was 30 degrees, and on July 31 (19.13 degrees), in the current era with a 23.5-degree axial inclination.

19.50 degrees s of w -- This angle to **Cerro Zempoaltepec** defines the same day as above, but as an antipodal sunrise.

La Venta era marker:

Both of the site identity angles shown above (19.36 and 19.50 degrees n of w) also locate a sunset on August 13 before 685 BC. Thus at this site an era-ending marker is combined with a zenithal passage of the Sun. The site of **Izapa** will accomplish the same, but for the date of August 11, and conformed to the current axial inclination of the Earth.

15.22 degrees n of w -- This angle to **Citlaltepctl** defines a sunset on April 19 (15.27 degrees), for a 30-degree axial inclination. **Citlaltepctl** is the highest peak in Mexico. (See notes, below.)

15.32 degrees n of w -- This angle to **Volcan La Malinche** defines the same sunset on April 19 as above, for a 30-degree axial inclination. **Volcan La Malinche** in direct line with **Citlaltepctl**. (See notes, below.)

11.06 degrees s of w -- The angle to **Popocatepetl** defines a sunrise for the day of February 28 (11.00 degrees), as the start of the era after 747 BC, but selected while the axial inclination was still at 30 degrees, that is, before 685 BC.

Site axis at 8 degrees w of n -- The central axis of the present monuments at **La Venta** determine an orientation for the date of February 28th (8.61 degrees), based on the current axial inclination of 23.5 degrees. Actually, the following day, March 1 might be a better fit (8.21 degrees).

23.65 degrees north of west -- The angle with **Cerro San Martin (Queretaro)** defines a summer sunset on July 9th (23.62 degrees) in the current era. This may be a coincidence.

Setting of the Pleiades -- There are two coaxial alignments for the setting of the Pleiades in 685 to 600 BC to the mountains **Ixtaccihuatl** (12.79 degrees) and **Volcan San Martin Pajapan** (13.27 degrees).

La Venta notes:

The site location was likely established after 747 BC, as shown by the fact that there is an alignment for February 28. This was selected while the axial inclination was still at 30 degrees. This suggests that the 15.22-degree alignment (a sunset n of w) with **Citlaltepctl** (and **Volcan La Malinche**), defines an antipodal sunrise (s of e) for the date of April 19 (of 1492 BC).

Thus the 1492 BC "era-ending" date of **San Lorenzo** was duplicated at **La Venta**, and the era-ending date for 3114 BC and 747 BC were added. These are site location alignments which could not be altered when the Earth's axis changed in 685 BC. A new alignment for the just previous era ending was established by selecting a reconstruction site axis as 8 degrees west of north.

Coincidentally, the two prior alignments at approximately 15.27 degrees, which had pointed to the 1492 BC era-ending dates of April 19th, now could be assigned to point to the 3114 BC era-ending date of August 13th at 15.49 degrees north of west.

Malmstrom, in "Archaeoastronomy in the Americas" (Ray Williamson, ed. 1981), shows the "Stirling compound," located adjacent (east) to the main structures (Compounds A, B, and C)

at **La Venta** as aligned 15 degrees east of north. I do not know the date of the Stirling compound, but the alignment could point directly to a northwest sunset (15.49 degrees) for August 12 of the current era. Malmstrom wanted to use this to establish an "August 13" alignment. This is unlikely to be so because the "Stirling Compound" is older than the remainder of the site, and thus built before 747 BC and before the invention of the Long Count. From site plans I have seen, the Stirling compound looks to have one edge aligned at about 20 degrees west of north, and another at 28 degrees east of north.

Tres Zapotes site identity:

19.67 degrees n of e -- The alignment with **Volcan San Martin Tuxtla** represents the day the Sun passes directly overhead on August 13 in the previous era, rising at 19.40 degrees n of e.

Tres Zapotes era markers:

The above 19.67-degree angle is also an alignment for August 12th, 3114 BC (19.83 degrees), for the era before 685 BC.

11.41 degrees s of e -- This angle with **Cerro Santa Martha** (Veracruz), is an antipodal alignment for a sunrise on April 19th, 1492 BC (11.98 degrees), conformed to the current axial inclination of 23.5 degrees. But this is unlikely since all the other alignments are conformed to the era before 685 BC. Thus this more likely represents the era-ending for 747 BC (11.02 degrees s of w), conformed to the previous axial inclination. The antipodal alignment here reflects across the north south axis.

30.87 degrees n of w -- This angle with **Nauhcampatepetl** for a summer sunset defines July 9th (30.28 degrees), but in the era of an axial inclination of 30 degrees, before 685 BC.

26.66 degrees n of w -- The alignment with **Cerro San Martin** (Queretaro) defines a sunset for the date of July 25th (26.47 degrees), but for the era where the axis is still 30 degrees.

26.91 degrees s of e -- The angle with **El Chichon** also defines a sunset for the day of July 25, but in antipodal fashion, and also for the era where the axis is still 30 degrees.

Pleiades setting: -- There are two alignments for the setting of the Pleiades in the era of 685 BC or earlier, to **Ixtaccihuatl** (12.56 degrees) and **Volcan San Martin Pajapan** (13.39 degrees).

Pleiades setting: -- There are two additional alignments for the setting of the Pleiades in about 100 BC, at 16.68 degrees n of w to **Citlaltepctl** and 16.43 degrees to **Volcan La Malinche** also n of w.

Tres Zapotes notes:

It is really strange to see the current era-ending alignments of July 9 and July 25 cast in terms of the previous axial alignment, and to find the much older alignment with April 19th -- of 1492 BC -- presented in terms of the current axial inclination. It is more likely, however, that this last is an era-ending for 747 BC, conformed, like the other alignments, to a 30-degree axial inclination.

Tres Zapotes is an old site, and it has been suggested that it became important when **San Lorenzo** was abandoned. This is likely, but because of the August 13th zenithal, and the existence of an August 12 alignment for 3114 BC, I think the site was not developed and located until after 747 BC. Before that time it would have been impossible to retrocalculate the era-ending date for 3114 BC.

```

Cerro De La Mesas site identity:

Interestingly, the Sun passes overhead on August 12th, but there is no mountain at 19.73 degrees for an alignment. This is also the era-ending marker for 3114 BC.

25.10 degrees s of e -- The alignment with **El Chichon (Chiapas)** is a winter solstitial alignment (24.90 degrees) or an antipodal alignment for a summer solstice sunset, for the current era. I think this is in error, that is, it is a coincidence, for all the other alignments are for the previous era.

Cerro De La Mesas era marker:

The zenithal passage of the Sun on August 12 also signals the era-ending of 3114 BC.

15.35 degrees n of w -- The alignment with **Volcan La Malinche** defines a sunset on April 19 (15.32 degrees) in the era with the axis at 30 degrees.

15.81 degrees s of e -- The angle with **Cerro Santa Martha (Veracruz)** marks an antipodal sunset on April 19 (15.55 degrees), in the era with the axis at 30 degrees.

10.58 degrees n of w -- This is a summer sunset over **Ixtaccihuatl** but defines an antipodal winter sunrise for February 28th (11.04 degrees), for an axial inclination of 30 degrees.

Cerro De La Mesas discussion:

At this site, dated to after 600 BC, we see the first solstitial alignment, although it might be coincidental.

```

Remojadas site identity:

31.47 degrees n of w -- This angle with **Nauhcampatepetl** defines a summer solstice in the previous era, with an axial inclination of 30 degrees (31.92 degrees).

Remojadas era markers:

4.89 degrees n of w -- The angle with **Ixtaccihuatl** marks the ending of the era on September 8, 2349 BC before 685 BC (5.22 degrees), conformed to the current axial inclination, as are all the other alignments at this site (except the possible solstice, above).

8.27 degrees n of w -- The angle with **Volcan La Malinche** marks an antipodal sunrise of date of February 28th (8.66 degrees), conformed to the current era.

23.74 degrees s of e -- The angle with **Volcan San Martin Pajapan** defines an antipodal summer sunset on July 9th (23.74 degrees), conformed to the current era.

23.42 degrees s of e -- The angle with **Cerro Santa Martha** (Veracruz) marks the antipodal day of the release of the plasmoid, July 14, 586 BC (23.00 degrees), conformed to the current era.

21.20 degrees s of e -- The angle with **Volcan San Martin Tuxtla** marks the antipodal day of the delivery of the plasmoid, July 25, 586 BC (20.77 degrees), conformed to the current era.

Remojadas notes:

The complete array of era markers which are presented, September 8, 2349 BC, February 28, 747 BC, April 2, 685 BC, and July 9th, 14th, and 25th, is amazing. All of these are presented under the current condition of a 23.5-degree axial inclination.

The solstice alignment is conformed to the previous 30-degree axial inclination, and is probably in error.

Zempoala site identity:

20.02 degrees n of w -- The angle with **Cerro San Martin (Queretaro)** defines the summer sunset for the zenithal passage of the Sun (at 89.92 elevation) on July 26th (20.59 degrees) conformed to the era after 685 BC. In the prior era the zenithal passage would have fallen on August 10.

Zempoala era markers:

10.54 degrees s of w -- The angle with **Popocatepetl** marks a sunset for the date of February 28th (11.09 degrees), but for the condition of a 30-degree axis.

6.71 degrees s of w -- The angle with **Ixtaccihuatl** marks an antipodal rise of the Pleiades for September 8, 2349 BC (6.69 degrees), for the condition of a 30-degree axis.

26.6 degrees s of w -- The angle with **Citlaltepetl** defines the day of the plasmoid strike on July 25th (26.64 degrees), but for the condition of a 30-degree axis.

Zempoala notes:

Again, era markers are presented as alignments only valid for the previous axial inclination. The site identification alignment could also be grouped with these. Interestingly, the site identity alignment became important after 685 BC because it fell on July 26 -- New Year's Day as established by **Teotihuacan**.

[Image: Teotihuacan alignments; plan view.]

Teotihuacan site identity:

The Sun passes overhead at 89.86 degrees on July 25th. This also marks the delivery of Jupiter's plasmoid at the Sun in 685 BC.

Teotihuacan era marker:

The axis of the site defines the setting of Sun at 15.60 degrees north of west for August 12, 3114 BC (15.64 degrees n of w) -- at right angle to the long axis of the site.

22.83 degrees s of e -- This angle with **Citlaltepētl**, the highest mountain in Mexico, suggests an antipodal sunset on July 15th (22.93 degrees), the day after July 14th (23.10 degrees).

The zenithal passage of the Sun on July 25 also marks the era-ending of 685 BC.

Pleiades setting: -- There are two antipodal alignments to **Volcan San Martin Pajapan** (18.65 degrees) and **Cerro Santa Martha (Veracruz)** (18.45 degrees). Both of these are correct for the era of AD 200 to 400.

The overhead passage of the Sun is also a marker for the current era.

```

Tlatilco site identity:

In the era after 685 BC, the zenithal sun passed over the site on July 26, a significant day, but there is no mountain associated with this.

0.479 degrees n of e -- This is a vernal equinox sunrise over the mountain **Nauhcampatepetl**, a very unusual alignment.

Tlatilco era markers:

19.62 degrees s of e -- The angle with **El Chichon** (Chiapas) marks a sunset for August 12, under the condition of a 30-degree axis.

14.75 degrees s of w -- The angle with **Volcan San Martin Pajapan** marks a sunset for the date of April 19th, 1492 BC (15.39 degrees), under the condition of a 30-degree axis.

14.51 degrees s of w -- The angle with **Cerro Santa Martha** (Veracruz) also marks a sunset for the date of April 19th (15.39 degrees), under a 30-degree axis, lining up with **Volcan San Martin Pajapan**.

11.62 degrees s of e -- The angle with **Volcan La Malinche** marks a sunrise for the date of February 28, 747 BC (11.09 degrees) for the era before 685 BC.

Pleiades setting: -- There are two antipodal alignments to **Citlaltepetl (Pico de Orizaba)** (13.31 degrees) and **Volcan San Martin Tuxtla** (13.00 degrees). These alignments were in effect directly after 685 BC.

Tlatilco notes:

The era markers, and the curious equinoctial site identity, suggest that this is a fairly old site, but established after 747 BC.

Tizatlan site identity:

19.78 degrees s of w -- The angle with **Ixtaccihuatl** marks the antipodal zenithal sunrise for July 26 for current era (20.57 degrees) or August 11 of the previous era (20.37 degrees).

Tizatlan era markers:

The zenithal passage is so close to the angle required to denote August 12, 3114 BC (19.94) before 685 BC, that it may as well be used as such. This is yet another case of the setting angle of the zenithal Sun being used also for an era-ending marker. However, see below.

14.62 degrees s of e -- The angle with **Volcan San Martin Tuxtla** marks an antipodal sunset for April 19, 1492 BC (15.38 degrees) under the previous 30-degree axial alignment.

29.44 degrees s of e -- The angle with **Volcan La Malinche** defines the date of July 14 (29.49 degrees), but in the era before 685 BC, with an axial inclination at 30 degrees.

Pleiades setting: -- There is an antipodal alignment with **Citlaltepctl (Pico de Orizaba)** (18.66 degrees) representing a date of AD 200.

Pleiades setting: -- There is an alignment with **Volcan San Martin Pajapan** at 16.64 degrees, and an alignment with **Cerro Santa Martha** at 16.36 degrees. Both point southeast and are thus antipodal. The horizon locations represent the setting of the Pleiades after culmination in about 100 BC.

```

Cuicuilco site identity:

There seem to be no site identity alignments. The zenithal Sun passes over on August 11, setting at an angle nearly identical to the angle needed to mark the era-ending of August 12, 3114 BC. There are no mountains associated with these.

Cuicuilco era markers:

... prior era

A possible dual use of the zenithal passage of the Sun is noted above.

10.68 degrees s of e -- The angle with **Volcan San Martin Tuxtla** defines an antipodal sunset for the date of February 28 (11.08 degrees), under the condition of a 30-degree axial inclination.

30.47 degrees s of e -- The angle with **Cerro Zempoaltepec** defines (surprisingly) an antipodal sunset date of the suspected initial flare-up of Jupiter on July 9 (30.44 degrees), and under the condition of a 30-degree axial inclination.

26.06 degrees s of w -- The angle with **Popocatepetl** likewise defines the antipodal sunrise date of the suspected delivery of the plasmoid by Jupiter on July 26 (26.91 degrees), under the condition of a 30-degree axial inclination.

... current era

12.67 degrees s of e -- The angle with **Volcan San Martin Pajapan** defines an antipodal sunset for the date of April 19, 1492 BC (12.03 degrees), for a 23.5-degree axis.

12.39 degrees s of e -- The angle with **Cerro Santa Martha** (Veracruz) additionally marks the date of April 19th. The mountain is almost the same distance from the site as **Volcan San Martin Pajapan**.

8.45 degrees s of e -- The angle to **Citlaltepetl** defines an antipodal sunset for the date of February 28th (8.67 degrees), under the present conditions of the sky. This duplicates the 10.68-degree alignment.

5.07 degrees n of e -- The angle with **Nauhcampatepetl** marks September 8, 2349 BC (5.23 degrees) for the current era.

Pleiades setting: -- In addition to a sunset for September 8 in the era before 685 BC, there is an antipodal alignment for the setting of the Pleiades to **El Chichon (Chiapas)** (18.15 degrees).

Cuicuilco notes:

Many era markers, but no site identification.

Tlapacoya site identification:

There seem to be no site identity alignments, although it could be held that the zenithal sun would mark the era-ending of August 12, 3114 BC. But there are no mountains associated with this.

11.41 degrees s of e -- The angle to **Volcan San Martin Tuxtla** marks the winter sunrise for the date of February 28th (11.08 degrees), but for the condition of having the inclination of the Earth's axis at 30 degrees.

5.86 degrees n of e -- The angle with **Nauhcampatepetl** marks an antipodal sunset for September 8, 2349 BC (5.23 degrees).

23.74 degrees s of e -- The angle to **Ixtaccihuatl** marks an antipodal sunset for the date of July 9th (23.79 degrees).

Setting of the Pleiades -- In addition to the sunset alignment for September 8, 2349 BC, there are two alignments for the setting of the Pleiades in 685 to 600 BC to **Volcan San Martin Pajapan** (13.44 degrees) and **Cerro Santa Martha (Veracruz)** (13.16 degrees) and one for the era of AD 200 to 400 to **El Chichon (Chiapas)** (18.93 degrees).

Cholula site identification:

19.66 degrees n of e -- The angle with **Nauhcampatepetl** defines a zenithal sunrise for July 27th (20.29 degrees).

32.02 degrees n of e -- The angle with **Volcan La Malinche** is the summer solstice sunrise of June 21 (31.94 degrees), for the condition of having the inclination of the Earth's axis at 30 degrees. I doubt the validity of this alignment, since all the other alignments are conformed to the current era.

Cholula era markers:

12.09 degrees s of e -- The angle with **Volcan San Martin Pajapan** defines an antipodal sunset for the start of a previous era, on April 19, 1492 BC (12.02 degrees), but under the current axial inclination.

11.74 degrees s of e -- The angle with **Cerro Santa Martha** (Veracruz) also defines an antipodal sunset for the date of the start of the previous era, on April 19, 1492 BC (and under the current axial inclination). **Cerro Santa Martha** is almost the same distance from the site as **Volcan San Martin Pajapan**

5.66 degrees s of e -- The angle with **Popocatepetl** defines September 8, 2349 BC (5.22 degrees).

Setting of the Pleiades -- In addition to the sunset alignment for September 8, 2349 BC, there are two alignments for the setting of the Pleiades in AD 200 -- 400 **Ixtaccihuatl** (18.48 degrees) and **El Chichon (Chiapas)** (18.71 degrees).

Cholula notes:

Except for the possible solstice marker under the condition of a 30-degree axis, all the alignments are conformed to the current axial inclination.

I am including **Monte Alban** as a matter of reference. I have not checked this site against the mountains of Veracruz and the Valley of Mexico because it is too far south. **Monte Alban** is discussed in the chapter "Olmec Alignments."

Endnotes

Note 1 --

The short javascript program is available on line which can be used to find the location (in degrees from east) and time of sunrise and sunset for any axial inclination and latitude. Originally written to predict the angle of shadows for outdoor filming at various locations and dates. At [\[saturniancosmology.org/sun.html\]](http://saturniancosmology.org/sun.html).

Documentation: The program uses elements of spherical geometry to determine the location of the Sun. The year is divided up into two halves of 182 days each with the solstice of June 21 as day zero. Thus the quarter day is neglected. The actual calendar days of the equinoxes and solstices move two days in the year, because our calendar varies between 365 and 366 days. In this program the leap days are neglected, summer solstice is set to "day zero" and the

remainder of the year is divided up into two 182-day segments.

Since the Sun travels a little over one degree on the ecliptic each day, a sunset will differ from sunrise by about a half degree at most (but considerably less near the solstices). Except for this, the program should be fairly accurate. Small differences in latitude or axial inclination will not significantly affect the results.

The angles are for sunrises. To find the equivalent sunset angle, find the difference between the current sunrise and the next day. One half of this difference, when added to a sunrise angle, will give a good approximation for the corresponding sunset angle in the tropics.

The program will on occasion crash at the equinox (a divide by zero problem). Live with it, or change the axial inclination from 23.5 to 23.45 degrees (the actual value).

Note 2 --

The line of sight distance is at a right angle to the radius of the Earth. Thus we have from the pythagorian:

hypotenuse squared = leg1 squared + leg2 squared

$$(r + h)^2 = r^2 + d^2$$

$$r^2 + 2rh + h^2 = r^2 + d^2$$

solving for d, $d^2 = r^2 + 2rh + h^2 - r^2$.

Since h is a fractional mile, h^2 is very small compared to $2rh$, and can be neglected.

An inclination of 25 Degrees

And here we shall take up the demonstration, revelation, and account of how the axis changed three times since the end of the "Age of the Gods" (in terms of the opening words of the *Popol Vuh*). The need to question the axial inclination became clear on reading an essay by Euan MacKie, which I will discuss further below.

Let me suggest that after 3147 BC the inclination of the rotational axis of the Earth (to the plane of its orbit) might have been 25 or 26 degrees. The pyramids and the Sphinx, representing some of the earliest of Egypt's constructions, hint at this.

It is possible to suggest that the Sphinx was constructed to face the rising Sun at the solstice, when the current real Sun replaced Jupiter after Jupiter entered the asteroid belt at the end of the first dynasty in about 2860 BC (as I calculate it). If the inclination of the Earth's axis was 25 or 26 degrees, the most northerly location of the rising Sun, at the summer solstice, would occur at 29 to 30 degrees north latitude, which is the location of the Sphinx.

Assuming the virtual disappearance of Jupiter as the Midnight Sun after the end of the first dynasty, it could be suggested that the Sphinx was specifically constructed after the end of the first dynasty as a beacon to watch for the return of the Midnight Sun, Jupiter, which also traveled on the ecliptic, like the Sun.

Jupiter moves very slowly on its path around the zodiac. The location directly east from the Giza plateau would be where Jupiter was seen at the extreme of the ecliptic, and thus also at its earliest. If Jupiter had nearly disappeared, that is, had lost its giant lower mountain because it had entered the asteroid belt and no longer looked like Osiris moving through the sky as a mummified form, then perhaps the Sphinx was an attempt to coax his return. That would place the construction of the Sphinx after the start of the second dynasty, after 2860

BC.

Colin Reader, in "Giza Before the Fourth Dynasty" JACF (2002), suggests that the Sphinx dates from the first or second dynasty -- long before the Giza pyramids were constructed (in the fourth dynasty). It existed before the building of Khafre's causeway and mortuary temple. The walls of Khafre's mortuary temple are wedged into the enclosing wall of the Sphinx temple (the temple building actually is also a late construction). Khafre's mortuary temple was likely built after the Sphinx's temple building was constructed. The Sphinx itself is older than either.

The other suggestion for the placement of the Sphinx, might be as a vigil for Horus the hawk who had flown from east to west every day or night for 4000 years, although actually this was Saturn seeming to revolve around the Earth (due to the Earth's rotation). Saturn as Horus would also have appeared on the ecliptic, at least, apparently so. This concept might place the construction of the Sphinx at an even earlier time. A much earlier construction of the Sphinx (5000 BC to 9000 BC) was suggested by Robert Schoch, writing in *Voices of the Rocks* (1999), based on water damage. See the chapter "Pyramids and Henges" for a discussion on dating the Sphinx.

For the Giza plateau construction of the Sphinx a 25- or 26-degree inclination would suffice to suggest that the Sun traveled a completely different path at an earlier date. A 25- or 26-degree axial inclination could then be suggested as the initial condition of the inclination of the Earth's axis after release from Saturn in 3147 BC.

Saturn's inclination to its orbit is 26.7 degrees, but this is likely a numerical coincidence to the early inclination of the Earth's orbit. It would always have been this value. The 25-degree axial inclination of the Earth is with respect to the new (and current) orbit, and would have been something different when the orbit of the Earth paralleled the orbit of Saturn. [\[note 1\]](#)

A 25-degree inclination accounts well for the construction of the Sphinx as resulting from a change in the celestial display of the mountain of Jupiter which disappeared in about 2860 BC. At that time Jupiter entered the asteroid belt and its huge lower form disappeared. The coma would have become smaller in diameter. It is almost certain that this was the crisis that exchanged the second dynasty for the first. Current estimates list the end of the first dynasty as 2890 BC. We think political influences, but of overriding importance in antiquity was religious concepts.

It accounts well, however, if it can be agreed that the Egyptians considered the overhead passage of the Sun as considerably more important than its easterly rising. This duplicates the attitudes of the Olmecs of Mesoamerica, who, following the theories of Clyde Winters, likely had North African origins.

Nekhen, the center of early religious activity in Egypt, is at 25.1 degrees north latitude. At Nekhen the Sun would have traveled to stand directly overhead (90 degrees) at noon at the

spring and fall equinox if the Earth's axial inclination had been 25.1 or 25.2 degrees. This is because Nekhen is located at a latitude equal to the axial inclination of the Earth.

About Nekhen, Wikipedia reports:

"[Nekhen] was the religious and political capital of Upper Egypt at the end of the Predynastic period (c. 3200-3100 BC) and probably also during the Early Dynastic Period (c. 3100-2686 BC). Some authors suggest occupation dates that should begin thousands of years earlier."

As I have previously pointed out, the inclination of Earth's axis and the rotational axis of Saturn did not match in the era before 3147 BC. The ancients insisted that the earlier polar apparition rotated in a circle "without cease," but this would have consisted of Saturn traveling in a circle in the north sky. It would not be the rotation of Saturn about itself.

It is the difference in the inclination of the rotational axis of Earth and Saturn which would have seemed to make Saturn rotate in the sky. The inclination of the rotational axis of the Earth to this original orbit (inclined at 4.51 degrees to the Sun's equatorial, like Saturn's orbit) would thus have been 28.5 degrees. The difference from the absolute inclination of Saturn is not much, only about 2.5 degrees. But this would result in a 5-degree diameter circle that Saturn would have traveled in the north sky. This is still 10 diameters of the Moon. [\[note 2\]](#)

Despite a certain elegance of the above speculations, there are problems with these concepts. For one, the axial inclination was 30 degrees after 1492 BC. The 30 degree inclination might have been in effect since 3147 BC (although I doubt that). Calendars and orbits will not indicate any of those possible changes. The only secondary indication would be the occupation by humans of the region above the Arctic Circle, but this will be influenced by the overall climate, which was considerable better before 1492 BC.

At this point I would suggest that after 3147 BC the Earth might have had an axial inclination of 25.2 degrees (following G.F.Dodwell). Released from Saturn, it started on an orbit around the Sun, where the location of the release constituted the aphelion of the orbit -- May 28th, apparently. This would be the location Earth would return to yearly until the orbit changed again at a later date.

When did the inclination change to 30 degrees? I would suggest that most likely this happened in 1492 BC. The Earth apparently not only tilted to a horizontal position, but it took the Earth 13 months to upright itself again. There are enough incidental memories and legends to substantiate this last. The number of months varies, but is much larger than expected for a gyroscopic reaction. The massive gyroscopic reaction torque suggests the possibility of large changes in orbital parameters, and in fact the Earth's orbit became 30 percent larger.

Additional Changes

The need for considering possible changes in the axial inclination was initiated by an essay by Euan MacKie, "Megalithic Astronomy and Catastrophism," in *Pensee* magazine (1974). MacKie based his information on the research of Alexander Thom as reported in Thom's *Megalithic Sites in Britain* (1967).

Absolutely typical of the befuddled attitude expressed by both MacKie and Thom, which does not seem to ever question what both learned in grade school, is the insistence on determining calendars over and over again with 300 separate alignments of stones, and the insistence that these were all to the benefit of farmers, "so they would know when to plant."

So I tackled the question of why so many stone arrays and circles needed to be set up in Great Britain over a period of 200 years, and then abandoned almost completely. I looked at the possibility of a change in the axial inclination of the Earth (although generally humans do not care about that), the path of the Sun and the path of the Moon (although, again, no one cares), and finally, the possibility that this represented another set of destructive close calls by Mars.

I should warn the reader that I do not, in the following, reach a definitive conclusion about megalithic astronomy, or the inclination of the Earth's rotational axis. Intrusions by Mars, however, fit well with other archaeological data.

Introduction

MacKie discusses two locations in Scotland, three standing stones at Ballochroy (55.70 north latitude), aligned parallel with three mountain peaks 18 miles (29 km) away, and one at Kintraw farm (Argyll) at 56.12 north latitude facing southwest to a mountain peak 28 miles (32 km) away.

[Image: Standing stones at Ballochroy, Scotland. After stonesofwonder.com.]

MacKie introduces his article with the following:

"The dating of the megalithic observatories to the period from about 2000-1800 B.C. seems fairly secure and puts them firmly into the epoch preceding Velikovsky's major cataclysms of the 15th century B.C. In spite of this, the alignments so far identified do fit well with the present celestial system retrojected to the period concerned."

Despite further hemming and hawing, here is how the article was understood by followers of Velikovsky: it dismissed Velikovsky's claims to changes in the inclination of the Earth's axis, changes in the length of the year, relocation of the geographic pole, and a number of other changes. I will attempt to clear some of this up.

Let me also point out that Dwardu Cardona, in "The Cairns Of Kintraw" (Kronos 1979), and in a second article, all but demolished the contention of a megalithic alignment with the Sun at the solstice at these particular locations, summing it up as, *"... given enough stones and a mountainous horizon, some celestial occurrences are apt to line up with something,"* and this despite the fact that Thom initially considered these two locations (Kintraw and Ballochroy) to be the most important solstitial sites. More on this further below.

[Image: Progress of the Ballochroy solstice sunset; after Thom.]

I was similarly ready to dismiss the alignments found by Thom, especially since a perusal of Thom's writings shows him expanding his ideas well beyond what might otherwise be acceptable. One secondary result of his investigations has been the definition of a "megalithic

yard," for which, more than anything else, he has been faulted. But a megalithic yard is easier to mock than his proposed alignments, since almost no one knows anything about axial inclinations, solar declinations, and the equation of precession.

The claims that megalithic alignments like these are seen throughout the world during this period (meaning, as usual, throughout Europe or the UK), are not meaningful. This could easily be another resurgence of the insane interest in circles of our ancestors which had been interrupted in 2193 BC.

The evidence brought forward by Thom is that the inclination of the Earth's rotational axis with the normal to the plane of the orbit (which I will simply call "inclination" or "axial inclination") could be derived from today's value of 23.5 degrees in a series of minute changes resulting in an "average" inclination of 23.9 degrees -- 0.4 degrees more than today. Suggesting a total change of 0.4 degrees in 4000 years is an extraordinary uniformitarian claim. MacKie attempted to verify this for the two locations discussed here, one for a summer solstice position at Ballochroy, the other for a midwinter solstice at Kintraw.

[Image: Standing stone at Kintraw, Scotland. After Thom.]

I had established earlier in these texts that the inclination of the axis was 30 degrees before 685 BC, and was ready to suggest that this might have continued without interruption from 3147 BC. Here, however, is different information, comfortably fitting Establishment assumptions that the inclination of the axis has always been the same as today, or nearly so.

What I should point out, first, is that the obsession with finding these solstitial sunsets existed only in the period from 2000 BC to about 1800 BC, and second, that the reported values of the axial inclination (actually the Sun's declination from the equatorial, which accounts for uneven horizons) are not all that close to the expected values. Retrocalculation from today places the best values in 1800 BC, says Thom (others have suggested 1600 BC). For the three standing stones at Ballochroy, MacKie arrives at a series of values which ranged from about

20 degrees to 24 degrees. Thom used an "averaged" inclination of 23.9 degrees, only 0.4 degrees different from today, but apparently based on a wider range of observations than these two.

The dating via a retrocalculation is based on observations made in 1909 of a slight tendency for the Earth's axis to move to the vertical. The span of observations for this was less than a decade, but the data was expected to hold for 3800 years into the past. The total change during that 3800-year period amounts to less than a half degree -- about the width of the Sun. Carbon-14 dating of the sites results in dates of about the same order -- a fortunate coincidence for the researchers.

A Critique by Cardona

In two articles in *Kronos* in 1979, "The Stones of Ballochroy" and "The Cairns of Kintraw," Dwardu Cardona critiques the alignments cited above. About Ballochroy Cardona writes:

"In fact, despite the latitude of 55.7 degrees, the 90 degree angle which separates the two sunsets at this locality as it is shown in Thom's plan, is only a myth. Neither the stone row nor the orientation of the stones 'points' directly to either of the two sunsets under consideration."

The "90 degrees," mentioned above, is derived from the fact that the solstitial sunsets at midsummer and midwinter are each 45 degrees north or south of west at this latitude for an axial inclination of 23.9 degrees. Actually the summer and winter sunsets are 87.8 degrees apart for a latitude of 55.7 degrees, and 89.0 degrees for a latitude of 56.12 north. We could say "about 90 degrees." But there is more.

For the sightings at Kintraw, Cardona points out that the intended target, an island 18 miles away, could not be seen from the location of the menhirs. Additionally he writes:

"Then, in 1969, Thom gave us a new diagram with a new set of lines. The line from the twelve foot menhir which runs through the centre of the stone 'circle' is no longer shown as indicating Beinn Shiantaidh. It is now shown as pointing to Dubh Beinn. What was a solar sight line has now become a lunar one."

At this point that Cardona makes his observation about "... given enough stones"

Skipping most of these critiques, let me instead simply point out that if Thom held these two sites to be the most valid of the 300 studied, the critique could be extended to all the other data, and suggest that none of the other observations are valid alignments of solstice sunsets for an axial inclination of 23.5 or 23.9 degrees.

Calendars

The expressed notion of these two reputable researchers and astronomers is that all the solstitial markers (throughout Scotland and England) represented efforts at establishing a calendar. It is hard to take this seriously. We are even told that this was to the benefit of local farmers, who would then know when to plant their crops, and even, as one unrelated astronomer of note claims about calendars, "when to harvest." Do reputable astronomers ever plant flowers in their front yard? [\[note 3\]](#)

Certainly it is not likely that any of this represented efforts at establishing a calendar, despite the fact that China, Babylon (in a late retelling), the Olmecs, and the Hebrews (as implied in Exodus) all recall settling on a calendar after 2349 BC -- and in many cases settling on a revised calendar. But, more important, calendars are not used by farmers, who plant by the weather, but are used to determine religious feast days. Archaeologists forget that our ancestors were absolutely obsessed with religious observances.

The date of the equinox is much easier to find than the date of the solstice. In fact, from what we know of ancient calendars, it appears that the year almost universally started with the fall equinox, or with the culmination of the Pleiades, two days later -- even with later revised calendars. The culmination of the Pleiades also remained a major religious feast day. For this a calendar, or the determination of the date of the solstice, would not be needed. It would be very obvious from a look at the skies.

The repeated sighting locations for the solstitial sunset (if these are what these standing stones represent) look like absolutely desperate attempts at determining the course of the Sun as it changed its travel in the sky. I should add "or something," because maybe it was not the Sun that was being tracked.

Retrocalculation

The reader will have asked, how can the uniformitarian approach determine that 1800 BC is an exact extension backward of today's celestial parameters and conditions? This is called "retrocalculation" (Mackie calls it "retrojection") and involves the conviction that the year has always been 365.24 days long, that the Moon has always taken 29.5 days to complete a month, and that the established precession of the equinox has always been in effect. Thus Thom will claim that we are looking at the sky of 1800 BC, which, however, cannot be identified from the locations of the Sun or Moon, but only from the stars -- of which he identifies one, Spica, which he later withdraws from consideration.

It is this last, the precession of the equinox (along with the inclination of the axis), which determines where the Sun would rise or set against the backdrop of the stars. As an exercise in applied uniformitarian astronomy, this is easy to find. So the proper coincidence of horizon sunsets at the summer solstice in the remote past is simply the application of the current value of the precession (measured, for example, in years per degree, as below) to today's skies. That will rotate the skies (the stars) about 52 degrees along the horizon in order to

reach 1800 BC -- although there is no way to check that.

Thom's value, determined from AD 1967 (when his book was published), would be:

$$(1800 + 1967) / 72 = 52.3 \text{ degrees}$$

This value, which has been independently derived by Thom and by others, can be checked against what I hold to be the case: (1) there was no precession of the equinox before 747 BC, and (2) in 685 BC the dome of the skies moved 15 days forward.

$$(747 + 1967) / 72 + 15 = 52.7 \text{ degrees}$$

Is that close enough? The change in the equinox in 685 BC, which has been solidly established in previous texts, is completely responsible for presenting to archaeologists a picture of absolute uniformity.

I should point out that Thom's calculations are actually not quite as simple as this. He uses a slight adjustment in the value (in degrees per year), originally derived by Simon Newcomb between AD 1900 and 1909, and assumes that this can be extended backward in time by nearly 4000 years. The problem is that this adjustment formula has almost no guarantee of validity, both because of the limited data on which it is based and especially since historically the precession of the equinox has been recognized as varying. [\[note 4\]](#)

I must say I have no idea how such certainty about the date of 1800 BC was arrived at. But it is of great interest that the 15-day shift into the future in 685 BC can account for all of the change since 1800 BC.

Considering Mars

I have considered the possibility that the monuments might have something to do with the Sun, or with the Moon, but except for the muddled set of changing observations, these two tell nothing. I therefore considered Mars and Mercury. This possibility has already been broached in the chapter "The Day of the Dead." It involves close approaches of Mars during the end of the Early Bronze Age.

No reputation of insane destructiveness ever became attached to Mercury. The burning and melting of hilltop forts or citadels in Scotland was entirely due to Mars having inched south along its tilted orbit, but moderated by the greater distance between Mars and Earth at the higher level.

Scotland did not have the populous cities of the Eastern Mediterranean region. Some 60 stone structures were damaged in Scotland, with additional ones in northern Europe (there are about 200 in total).

The destructions in Scotland involves one of the sets of dates for Middle Eastern destructions recorded by Claude Schaeffer in *Stratigraphie Comparée et Chronologie de L'Asie Occidentale* (1948). He lists (among other things) a date of 1700 BC when many urban centers in the Middle East were destroyed. The date of 1700 BC is one from his series of dates which cannot easily be moved to a different period, for instance, by imposing our knowledge of the fictional Greek "Dark Ages."

To be included in Schaeffer's listing of cataclysmic archaeological conditions, the disturbing elements had to include earthquakes and firestorms. This would signify close contacts with Mars -- very close. This had been the case for a period of 300 years some 1200 or 1300 years earlier starting in about 3070 BC. This would happen again for a period of (only) 120 years, some 1000 or 1100 years later, starting in 806 BC. Others have pointed out that fires were the predominant cause of destruction.

Adding the known starting date (3067 BC) for the close passes of Mars after 3147 BC, and the start of close passes in the 8th and 7th century BC (806 BC), and dividing by two, results in a starting date of 1936 BC as a likely onset of this set of "contacts" by Mars. This falls in the center of Thom's era of investigation, and will match Schaeffer's date if this represents a midpoint.

I am suggesting, therefore, that close passes by Mars were the concern among the Scots and many other people -- China, India, and portions of northern and central Europe.

Why would the solstice be involved, if indeed it was? Actually, only two dates would qualify for a close contact by Mars. That would be dates near the equinoxes. I think the solstice had nothing to do with any of the monumental constructions.

The condition of Mars overrunning the orbit of Earth would continue as long as the perihelion of Mars's orbit fell inside the orbit of Earth. Lynn Rose and Raymond Vaughan in 1994, in proposing a solution to the data of the *Venus Tablets of Ammizaduga*, reported that in 670 BC (some years after the nova event of 685 BC) the eccentricity of the Earth's orbit changed significantly (from 0.10 to 0.0+). This means the orbit of Earth became nearly circular, and was no longer overrun by Mars.

Summary

Is the conviction of uniformitarian astronomers that the Earth's axis was inclined (as it was supposed to be) at 23.9 degrees in 1800 BC correct?

Not likely. All indications are that a different axial inclination was in effect since remote antiquity, and perhaps since before the beginning date of the era of interest to Alexander Thom.

Can this be squared with my conviction that after 1492 BC the inclination of the axis would have to be 30 degrees, and remained at that value until 685 BC?

It can, although that is another matter. I am on an entirely different path from Thom and MacKie. I can only reconcile their finding as some sort of mistaken reading of the facts. Frankly, I do not see how the finding of an "average alignment of 23.9 degrees" could be derived except through a driving conviction in the dominant paradigm of uniformitarian archaeology. It is a convincing fiction only in the eyes of those who wish it to be that way.

What might be the reason for the 200 years of activities, erecting circles and lines of large standing stones as well as single stones, by the tribes of Scotland (and apparently throughout northern and central Europe)?

It was most likely the interference of Mars with Earth between 2000 BC (I calculate this as 1936 BC) and 1800 BC. Since Mars traveled on an orbit inclined by 1.85 degrees to the orbit of Earth (the ecliptic), Mars would have inched down (to the south) over the course of one or two days when Earth and Mars were close together at the spring equinox (and the reverse in the fall). Mercury was located some 100,000 miles above Mars, and electrical contacts with Earth would not have been likely.

Endnotes

Note 1 --

Quoted from <http://www.science-frontiers.com/sf030/index.htm>:

"Australian astronomer G.F. Dodwell has analyzed the observational records compiled for the many gnomons erected all over the civilized world during the past 4,000 years. Gnomons are vertical markers that cast shadows from which the local latitudes can be computed. (All one needs are the measurements of the shadow lengths on the longest and shortest days of the year.) The earth's tilt or obliquity of the ecliptic may also be calculated from gnomon data -- and therein lies the anomaly. The tilt of the earth's axis is supposed to vary cyclically between 22 and 24.5° over a period of some 40,000 years due to the pulls of the moon, the sun, and the planets on the earth's equatorial bulge..."

[Image: Obliquity data since 2300 BC, after Dodwell.]

"Tilt angles computed from ancient gnomon observations deviate markedly from the theoretical curve. The alignment of the ancient Egyptian temple at Karnak and other oriented sites extend the deviation toward the date 2345 B.C. [This is the asymptotic date for the plotted data.] Either the ancient observations were systematically in error all over the world or the earth's tilt angle changed in historical times."

Dodwell's earliest inclination is 25.2 degrees, derived from a pylon at the temple of Karnak, built in 2045 BC. Dodwell assumes an exponentially declining sine curve for the values, as if the Earth was impacted in about 2345 BC and wobbled back and forth in decreasing swings. Not entertained is the possibility that the Earth's tilt always was 25.2 degrees.

Note 2 --

Since the orbit of Saturn is inclined at 4.51 degrees to the Sun's equator, and the Earth's current orbit is inclined at 7 degrees to the Sun's equator, there is a 2.49 degree difference between the inclination of the Earth's original parallel orbit to Saturn's orbit. This places the inclination of the Earth's axis at 28.5 degrees to the plane of the orbit before 3147 BC.

Compare this to Saturn's inclination to its orbit, which would not have changed since 3147 BC, and it will be seen that the axis of rotation of the two planets did not coincide, although the measures (26.7 and 28.5 degrees) are close, as seen in the sky they are still two finger-widths apart in radius and four in diameter.

The aphelion of the Earth's orbit today is July 4th or 5th (it varies with leap years).

Note 3 --

Phillip Pait, in *Death From the Skies* (2008), which sports a *Reader's Digest* version of traditional and consensual knowledge -- what everyone supposedly knows -- writes:

"... astronomy is actually the world's oldest profession: early agricultural civilizations needed to know when to plant their crops and when to harvest, and the changing skies gave them their clues."

"The Sun was worshipped, and the Moon. This evolved into the belief that all the gods lived in the sky."

Could he be any more wrong? The Sun and Moon have never been worshipped anywhere except in the imaginations of astronomers. Additionally, I would award the honors of being "the world's oldest profession" not to astronomers, but to a group of people of a different occupation.

Note 4 --

Euan MacKie reports:

"... this modern motion, when projected back into the past with the aid of the Newcomb formula, reveals that a solstice of 23 degrees 54 minutes existed at about 1800 B.C., a date which fits very well with the date of the standing stones derived from independent archaeological evidence [Carbon-14 dates]. Clearly, powerful arguments would need to be marshalled against this apparently neat coincidence if a catastrophic interpretation were favored."

Here is the powerful argument: The Newcomb formula determines the multiplier for precession of the equinox as, $(50.2564 + 0.0002222) * \{\text{years}\}$, where "50.2564" is the number of seconds of a degree per year, thus 50/3600 degrees, and .000222 is a very small additional multiplier. The inverse of 50/3600 is 72, which is the number of years per degree, and the value I used.

From <http://www.binaryresearchinstitute.org/>, a site which disputes Newcomb's formula, we have:

"Calculated precession rates over the last 100 years show increasing precession rates which produce a declining precession cycle period. There is no reason the relatively constant mass of the Sun and Moon torquing the Earth should produce such figures."

The idea of "the Sun and Moon torquing the Earth" is just made-up science nonsense (first introduced by Newton), which the above quoted text actually acknowledges. I have shown that it is the Moon's repeated entry into the Earth's plasmasphere which is at cause, and therefore precession is a function of the size of the Earth's plasmasphere. This, in turn, is controlled by the Sun's electrical field at the exterior of the Earth's plasmasphere.

Recovering the Lost World, A Saturnian Cosmology -- Jno Cook

Appendix E: Polar Relocations.

\$Revision: 42.32 \$ (flip.php)

Contents of this appendix: [\[The Source of the Problem\]](#) [\[Velikovsky's Moving Pole\]](#) [\[Data from 747 BC\]](#) [\[Earth as a Gyroscope\]](#) [\[Data from 1500 BC\]](#) [\[Flipping the Pole in 1500 BC\]](#) [\[Lack of Glaciation in Siberia\]](#) [\[Frozen Mammoths in 1500 BC\]](#) [\[Other Polar Relocations\]](#) [\[Endnotes\]](#)

The Source of the Problem

It is ubiquitous for the oldest legends to state that the Earth at one time flipped over, although this is also stated as the interchange of north and south compass directions, or east and west. Velikovsky's *Worlds in Collision* includes many examples (I'll list some below), but ultimately they are confusing, for no particular time period is pointed to. Most are generic statements, often introduced with "at one time."

Velikovsky attempted to use this information to suggest that the Earth indeed did turn over, and placed it in the era of 1500 BC, during the Exodus of Moses. There are only a few references which might point to 1500 BC, and even if coupled to the devastation and orbital changes of 1492 BC, they do not add up.

The Earth never turned over, although it likely did so partially. But it sure looked like the Earth flipped over: the compass directions were interchanged, and the Sun now rose where it had set the previous day. I'll suggest that nearly all the references to a change in compass directions or the Earth turning over, refer to the events of 3147 BC. Other changes refer to 2349 BC, to 747 BC, and to 686 BC. The details of the narratives almost always point to actual events, even if dates are never given.

For people throughout the world, who understood the large globe above the north horizon as the land of the Gods which was attacked by another God in 3147 BC and subsequently removed to the night skies of the south. This scenario was entirely different from our concepts. What was seen was the sudden relocation of the land ("earth") in the north to a location in the south. Saturn had been seen from below, surrounded by its rings. When Saturn was moved to the south (being flung away from its close orbit around the Sun), it took on a

completely different look.

The Earth, released from the grip of Saturn, immediately started to move up toward the Sun. Within weeks Saturn was seen from a completely different perspective. For the first time Saturn was seen with its rings edge-on or nearly so. The change over a period of weeks or months was noted: Saturn had teetered, and fell over. Saturn -- "the land" -- had fallen, had flipped over.

The fifth-dynasty Egyptian tomb texts of Unas (2345 BC) relate that his majesty, Osiris, died when he fell on his side at the riverbank. The river is the ecliptic, not the Nile.

The Maya *Chilam Balam* books read,

"Then Oxlahun-ti-ku [Saturn] was seized, ... and he was (thrown) on his back as well."

The removal of Saturn to the south skies was also seen as a reversal of north and south, or east and west. But there was no "east" and "west." That is a modern concept. There was only the main direction where the Gods resided and the land, and the left and right.

All the legendary snippets which have come to us have been translated to our conceptual base, or already recast in terms of east and west. In Mesoamerica, at a much later time, the main cardinal direction was the east where all the planets and stars could be seen to rise throughout the year. At 20 degrees latitude the Sun and planets do not swing as wildly between southeast and northeast in rising as they do at northern latitudes. The north and south in Mesoamerica were known as "the left" and "the right" (east was the forward direction). One can easily translate such directional concepts to the period shortly after 3147 BC, when the left and the right direction had interchanged.

There are similar concepts of "rising" and "setting" which have been altered to what we consider the correct order of nature. But, as Talbott and Cardona have pointed out, we use "rising" (and even "east") and "setting" for words that originally meant "brightening" and "dimming," as Saturn was experienced first during the night and then during the daytime.

Lastly, once we arrive in the period after 1500 BC, we have to allow for metaphorical use of "the Earth turning over" as a substitute for "calamity." The simile is a giveaway. The Egyptian scribe Ipuwer [page 120 of *Worlds in Collision*, Pocket Books edition] wrote after 1500 BC, "the land turned round like a potter's wheel." But Velikovsky inserts the word "over" in brackets after the first quoted use of Ipuwer's "turned round." A potter's wheel does not "turn over," it rotates. Subsequently Velikovsky simply quotes "turned over," rather than "turned round."

[page 88] *"According to the Lapland cosmogonic story ... the angry God spoke, 'I shall reverse the world, I shall bid the rivers flow upward; I shall cause the sea to gather itself up into a towering wall which I shall hurl upon your wicked earth-children, and*

thus destroy them and all life. ... (Jubmel) with one strong upheaval, made the earth-lands all turn over."

[page 104] *"The tradition of the Cashina, the aborigines of Western Brazil, is narrated as follows; 'the lightnings flashed and the thunders roared terribly and all were afraid. Then the heaven burst and the fragments fell down and killed everything and everybody. Heaven and earth changed places. Nothing that had life was left upon the earth.'"*

The references are both to the events of 3147 B and 2349 BC. The "towering wall" is the fall of the Absu in 2349 BC. Similarly "bursting of heaven" details 2349 BC.

[page 119] *"Pomponius Mela, a Latin author of the first century, wrote: 'The Egyptians pride themselves on being the most ancient people in the world. In their authentic annals ... one may read that since they have been in existence, the course of the stars has changed direction four times, and the sun has set twice in the part of the sky where it rises today.'"*

The reference is to the brief reversals of the travels of the Sun, twice in the 7th and 8th centuries BC, well within memory. Others had been forgotten. Herodotus presented the same information as Pomponius Mela in the book *Histories*. The change in the direction of the Sun's travel accounts also for the four changes in the dome of the stars. There is nothing in this statement that the reversals were permanent. The movement of the stars was very real, however.

[page 120] *"The Magical Papyrus Harris speaks of a cosmic upheaval of fire and water when 'the south becomes north, and the earth turns over.'"*

The reference is to events of 3147 BC.

[page 120] *"The texts found in the pyramids say that the luminary 'ceased to live in the occident, and shines, a new one, in the orient.' [Velikovsky adds:] After the reversal of direction, whenever it may have occurred, the words 'west' and 'east' were no longer synonyms, and it is necessary to clarify references by adding: 'the west which is at the sun-setting.' It was not mere tautology, as the translator of this text thought."*

The reference is to events of 3147 BC, especially if "a new one" is correctly translated. The "new one" is Jupiter.

[page 121] *"In the Ermitage Papyrus [Leningrad, 1116b recto] also, reference is made to a catastrophe that turned the 'land upside down; happens that which never (yet) had happened.'"*

Velikovsky added:

"It is assumed at that time -- in the second millennium -- people were not aware of the daily rotation of the earth, and believed that the firmament with its luminaries turned around earth; therefore the expression, 'the earth turned over,' does not refer to the daily rotation of the globe. Nor do these descriptions in the papyri of Leiden and Leningrad leave room for figurative explanation of the sentence, especially if we consider the text of the Papyrus Harris -- the turning over of earth is accompanied by the interchange of the South and North Poles."

True, these are not 'figurative' descriptions. They were actual, but the references are to events of 3147 BC. Poles were not known to the ancients. Directions were.

[page 121] *"Harakhte is the Egyptian name for the western sun. As there is but one sun in the sky, it is supposed that Harakhte means the sun at its setting. But why should the sun at its setting be regarded as a deity different from the morning sun? The identity of the rising and the setting sun is seen by everyone. The inscriptions do not leave any room for misunderstanding: 'Harakhte, he riseth in the west.'"*

"The Sun" is generally misinterpreted as our current Sun. In most societies "the Sun" was Jupiter during hundreds of years after 3147 BC. But the sun which rises in the northwest is Saturn. Saturn rotated counterclockwise in a circle around the North Pole. During the day it would show up faintly in the northeast, like the new moon against the blue sky, and then travel counterclockwise above the pole star.

At nightfall Saturn would be in the northwest, and would brighten, because it was now illuminated by the (normal) Sun. This is the location, of course, of the setting of the normal Sun, at least in summer at northern latitudes. Saturn would then proceed to rotate toward the east, below the pole star. This is also why many nations of the eastern Mediterranean started their day at nightfall.

This is the confusion we see about the later (regular) Sun rising where previously it had set. It might also apply to Jupiter which traveled on the ecliptic, and thus would be seen to rise in the east or northeast -- not in the northwest where Saturn had first brightened -- in effect rising.

[page 122] *"Plato wrote in his dialogue, The Statesman: 'I mean the change in the rising and the setting of the sun and the other heavenly bodies, how in those times they used to set in the quarter where they now rise, and they used to rise where they now set. ...'"*

This is a very general statement, which could be in reference to a number of eras in the past. The "heavenly bodies" is our terminology. What Plato meant is unsure. Probably he meant that Saturn used to "rise" -- that is, brighten -- while in the northwest at the start of nightfall.

[page 122] *"According to a short fragment of a historical drama ("Atreus") by Sophocles, the sun rises in the east only since its course was reversed. 'Zeus ... changed*

the course of the sun, causing it to rise in the east and not in the west."

"Not in the west," is added to the concept of the change in the Sun. Zeus here is Jupiter, who removed Saturn (the "Sun") from the northwest in 3147 BC and substituted himself (as the "Sun") during the following 500 years, but now appearing (as "rising") in the east skies as the Earth overtook Jupiter on its travels on the ecliptic. Every night, for months, Jupiter would thus also travel from east to west across the night sky.

There is a similar problem with the Greek name for the lands northwest of the eastern Mediterranean, "Europe," which was the "land of the sunrise." This has nothing to do with the "Sun" rising in the west. It is the brightening of Saturn (the "Sun") before 3147 BC seen in the northwest from Greece. It is amazing that these concepts were extant nearly 3000 years later (and the name is still in use 5000 years later).

[page 124] *"Caius Julius Solinus, a Latin author of the third century of the present era, wrote of the people living on the southern borders of Egypt: 'The inhabitants of this country say that they have it from their ancestors that the sun now sets where it formerly rose.'"*

[page 125] *"In the Syrian city Ugarit (Ras Shamra) was found a poem dedicated to the planet-goddess Anat, who 'massacred the population of the Levant,' and who 'exchanged the two dawns and the positions of the stars.'"*

I would guess this is Venus and the "massacre" refers to the blood in the sky (the "Day of the Dead") in 2349 BC. The "two dawns" is then likely a reference to the destruction by Venus in 1492 BC, although I have no idea what that is about, except, as I have earlier suggested, the fact that the Earth perhaps seemed to have partially inverted at the time of the Exodus. The apparent near inversion was due to the lack of sunlight, and the change in climate, which lasted some 40 years as the Bible and Mesoamerica tell.

[page 120] *"The reversal of east and west, if combined with the reversal of north and south, would turn the constellations of the north into constellations of the south, and show them in reversed order, as in the chart of the southern sky on the ceiling of Senmut's tomb. The stars of the north would become the stars of the south; this is what seems to be described by the Mexicans as the 'driving away of the four hundred southern stars.'"*

The "four hundred stars" ("400 lost boys") are recognized from Mesoamerican (Maya) sources as the Pleiades as well as all of the southern stars which showed up at the same time in 2349 BC. But "400" generally meant "lots of" in Mayan; it is often translated as "millions." But this probably deals with the change in the look of the sky in 685 BC, which I have detailed in the chapter "The Sibylline Star Wars."

The graphic depictions of stars by the Egyptians have a long tradition of utter disinterest in

the heavens. Starting from the sixth dynasty most often stars are depicted as so much wallpaper in tombs. Consider also the inaccuracies of the Egyptians in depicting the circumpolar constellations in circa 1500 BC, and the use of 24-day months (shown in Senmut's tomb, circa 940 BC). The reversal of the southern constellations cannot be taken seriously. It could only be accomplished by stopping and reversing the Earth's spin. Let me point out that if the Earth turns over, the Sun and the stars would still rise in the east, and in the same order.

On the other hand, a reversed chart does not surprise me at all. I should point out that star charts manufactured today often reverse directions also, and have done so consistently since late antiquity.

[page 126] *"The Eskimos of Greenland told missionaries that in an ancient time the earth turned over and the people who lived then became antipodes."*

[page 126] *"In the Tractate Sanhedrin of the Talmud it is said: 'Seven days before the deluge, the Holy One changed the primeval order and the sun rose in the west and set in the east.'"*

This is the condition directly before and after 3147 BC, when Jupiter yanked Saturn from its orbit, while the Earth, released from below Saturn, continued on a path around the Sun. Saturn, held to be the Sun ("Ra") was seen in the northwest before relocating to the south skies and diminishing in brightness. Jupiter (the "Bull of heaven"), outside the orbit of Earth, had already blazed up, and subsequently was recognized as Ra, the Sun.

I have earlier taken note of the fact that Jupiter apparently blazed up seven days before the flood of 3147 BC. The directions, east and west, are likely to be correct as the initial stage of the seven days of blinding light. I have used this relationship of Saturn and Jupiter to plot the changes in 3147 BC.

[page 132] *"On the Andaman Islands the natives are afraid that a natural catastrophe will cause the world to turn over."*

[page 132] *"In Greenland also the Eskimos fear that the earth will turn over."*

The references are, again, to the event of 3147 BC.

[page 132] *"The Egyptian papyrus known as Papyrus Anastasi IV contains a complaint about gloom and the absence of solar light; it also says: 'The winter is come as (instead of) summer, the months are reversed and the hours disordered.'"*

This refers to a period of heavy clouds (or a shadow), lasting for years, which appeared after an interplanetary lightning strike traveled through an ocean to cause vast clouds in the atmosphere, or across forests to cause carbon dust to be lifted into the stratosphere. This

would also happen when the Earth's polar axis took a long time to swing through a loop, which in effect would pass Earth through all the seasons in short order.

Gloom, of course, would make even a summer feel like winter. But the complaint is likely about the large climatic change after 1492 BC, and possibly a longer than usual gyroscopic reaction since Earth was impacted with a repulsive electric shock just below the equator in the eastern Pacific. The lever arm of the electric force was short, but it also hit closer to the Earth's center, causing a 30 percent increase in the orbit. This in itself changed climatic conditions worldwide. Grapes no longer grew in Scandinavia.

[page 132] *"The breath of heaven is out of harmony. ... The four seasons do not observe their proper times,' we read in the Texts of Taoism."*

The reference is to events of 685 BC. The Taoist doctrine is specifically a reaction to the changes of that year, and a suggested cause.

[page 315] *"In the tale of the southern Ute Indians, the cottontail is the animal that is connected with the disruption of the movement of the sun." ... "There is one instance more in the Indian story of the sun being impeded on its path and the ensuing world conflagration. Before the catastrophe, 'the sun used to go round close to the ground.' the purpose of the attack on the sun was to make 'the sun shine a little longer: the days were too short.' After the catastrophe 'the days became longer.'"*

This beautifully conflates two events close together in time, the Earth shock of 686 BC (involving Mercury), and the change in the axis in 685 BC. The longer days are in reference to the year after 685 BC, when the days would be longer, and the Sun would ride higher in the sky. Check this with the program [\[sun.html\]](#) for the latitude involved (about 30 degrees) and an axial inclination of 30 degrees. The Utes at that time lived much further north, where the difference between the travel of the Sun in summer would have been even more striking.

[page 317] *"Hindu astronomical tablets composed by the Brahmans in the first half of the millennium before the present era shows a uniform deviation from the expected position of the stars at the time the observations were made (the precession of the equinoxes being taken into consideration). Modern scholars wondered at this, in their opinion, inexplicable error. In view of the geometrical methods employed by Hindu astronomy and its detailed method of calculation, a mistake in observation equal to even a fraction of a degree would be difficult to account for. In Jaiminiya-Upanisad-Brahmana it is written that the center of the sky, or the point around which the firmament revolves, is the Great Bear."*

There are two ideas expressed here. That the axis of rotation of Earth was in the Great Bear before 685 BC, is entirely correct. The second piece of information, about tablets which "show a uniform deviation from the expected position of the stars," is also correct. These are known as the *Panchasiddhantika* tables recorded before 685 BC but not published until AD

600. They were saved for us despite the vagaries of time, when all its companion observations were probably discarded a 1000 years earlier.

[page 318] *"We possess the Chinese records of the longest and shortest shadows at noontime. These records are attributed to -1100. 'But the shortest and longest shadows recorded do not really represent the true lengths at present.' The old Chinese charts record the longest day with a duration which does not represent the various geographical latitudes of their observatories,' and therefore the figures are supposed to have been those of Babylonia [at 32.55 degrees latitude], borrowed by ancient Chinese, a rather unusual conjecture."*

Again, probably entirely correct for the era before 685 BC. (But these certainly were not "borrowed" records from Babylonia.)

Considering that throughout most of antiquity the Earth was held to be shaped like a pancake, it is inconceivable how statements about this pancake get transformed into a sphere by modern translators. I would suggest a wide range of misreadings, based on our preconceptions of the Earth as a globe.

Some of the above material does not deal with the Earth turning over, but has reference to the change in the inclination of the Earth's axis in 685 BC, something Velikovsky and most other investigators were not at all aware of.

Velikovsky's Moving Pole

Because the recent glaciations have been centered at odd locations away from the North Pole, a number of people have concluded that the North Pole shifted and the crust of the Earth followed -- sliding over the core to new locations. Velikovsky first invoked this idea in *Worlds in Collision*, and a number of writers of alternative cosmology tracts have followed suit. I have shown that glaciation had nothing to do with the North Pole. However, let me discuss these notions anyway. The following dismisses the concept of any permanent relocation of the Earth's spin axis with respect to the landmasses.

Two episodes of "pole shifting" were suggested by Immanuel Velikovsky. One instance, which concerns suspected events of circa 1500 BC, I disagree with and will discuss directly below. A second instance centers on the 8th century BC, which I will also expand on further below.

Velikovsky's suggestion in *Worlds in Collision* is that the Earth may have flipped over in 1500 BC, in addition to having the pole relocated by some 20 degrees. In support of this, Velikovsky supplies data for two changes of latitude for locations in the Middle East. The data, however, are from after 747 BC. I will address the changes in latitude first.

Data from 747 BC

Velikovsky's attempts to suggest that the Earth might have turned over are first of all based on Herodotus's information from the priests of Egypt, "Four times the Sun has set where it now rises." -- in effect that the path of the Sun had changed. The ancients could probably figure out that these represented two short-term changes in the path of the Sun, not a permanent condition. This happened in 747 BC and in 686 BC, accompanied by an Earth shock. Even so, if the Earth turned upside down, the Sun would still rise in the east, and would not "rise where it now sets." Spin does not stop. Perhaps one of these references is to the 40 days in 685 BC. [\[note 1\]](#)

The recollection of the priests was likely from a few hundred years earlier, not from three thousand years earlier. The more likely explanation, then, for this statement by the priests of Sais is that it reflects how the Sun, after rising, reversed direction and set where it had risen, to rise again from the same compass point shortly afterwards. That happened twice during the 8th and 7th centuries BC, and something similar may have also been recalled from 1492 and 1440 BC, although doubtful. In that it might have taken a day or even a few days, it would have been frightening. Herodotus writes this paragraph directly after a discussion of the demise of Sennacherib's army in 686 BC -- the year of the second Earth shock in the 8th and 7th centuries BC.

The *Iliad* and the *Odyssey* both record a Goddess holding back the sun at dawn or sunset for some hours only. Two Chinese records for the events of 686 BC state, "at night the stars fell like rain," which can be understood as an axial correction of short duration induced by a gyroscopic reaction.

Velikovsky also suggested that after the events of the 8th and 7th centuries BC the axis of the Earth no longer pointed in the same direction in space. That is correct, but was not the result of a close call by a planet. He cites the number of Greek and Roman writers who maintain that the center of the sky was previously located in "the wain" -- the constellation Ursa Major. Along with other sources, these all point to a change in the era of the 7th century BC. This specific change (in 685 BC) is dealt with in the chapter "The Tablets of Ammizaduga."

Other specific evidence offered by Velikovsky reduces the possible changes of the location of the geographical North Pole quite a bit. He cites evidence that Babylon moved 2.5 degrees south. Earlier records, before the 7th century BC, show Babylon located at 34.95 degrees. Today, and since most of the seventh century BC, it is located at 32.55 degrees latitude. I have discussed this in the chapter "Hezekiah and Babylon." It resulted from the change in the inclination of the Earth's axis in 685 BC. The invalid latitude was based on erroneous data for the length of the day -- in fact, the only error that could have been made. Babylon never moved. [\[note 2\]](#)

The second suggestion for a geographical relocation of the North Pole is from the curious

prediction by Isaiah that some 10 measures of a shadow gnomon would be returned as a sign from God that king Hezekiah would live another 15 years. Because the gnomon had been built under a previous king, the Bible reads, *"I will bring again the shadow of the degrees, which is gone down in the sun-dial of Ahaz, ten degrees backward,"* it has been assumed that the "degrees" which disappeared, did so at an earlier time, under the former king, Ahaz. This is an unwarranted addition to the facts as presented in the Bible passage.

The meaning of the passage changes if it is understood that the "lost degrees" were returned in the very same year that they were lost. Again we are dealing, in simple terms, with the change in the inclination of the Earth's axis in 685 BC, which moved the equinoxes forward by 15 days. Isaiah recognized this in the fall of 685 BC, when the Sun stood lower in the sky on the expected day of the equinox, but assumed the correct angle 15 days later. God's promise to return the "shadow of the degrees" was accomplished on March 21, 15 days after the expected spring equinox March 6. I have detailed this also in the chapter "Hezekiah and Babylon."

Lastly, Velikovsky mentions Ptolemy's star chart of the second century AD, which leaves off a number of stars seen at the north horizon, and adds other stars in the south, different from what stars are visible from Alexandria today. This suggests that Alexandria changed location with respect to the North Pole, perhaps after the time of Ptolemy -- the second century AD. We do not have a single record of this. The "additional stars" of the south skies include only a few well-known stars. If used for navigation, additional southern stars would have been mostly useless to Mediterranean navigators. The Southern Cross could be seen at the latitude of Baghdad until circa AD 700, however, after which it started to slip below the southern horizon. Far northern stars would not be needed. I have detailed the use of stars in navigation in "Olmec Alignments."

The implications we are asked to reach by Velikovsky do not hold up against the known fact that the star chart of Ptolemy -- which remained in use in Europe for over a thousand years -- was based on older sources, most likely Chaldean (Babylonian) records which were turned over to Alexander in 331 BC in Babylon. (These records supposedly dated to 2349 BC.) Ptolemy himself attributes Hipparchus (146 to 127 BC) as his source. Hipparchus made his observations in Asia Minor, north of Alexandria, and also would have constructed the chart for navigation. Star charts were certainly needed after 685 BC, when Sirius no longer traveled just below the equatorial.

These data points are either disproven or completely inconclusive. I do not think the Earth turned over in the 8th century BC as either claimed or insinuated by Velikovsky, although certainly the axis of rotation shifted permanently to point to a different location in space, but not until after 685 BC, and for completely different reasons. This did not relocate the Earth's North Pole geographically.

Earth as a Gyroscope

The Earth is a gyroscope, and reacts to outside forces as a gyroscope. If an external torque is momentarily applied to the Earth as a force offset from the center, in effect tipping the rotational axis, the Earth will produce a reaction torque which will sweep the pole through a circle to correct the imbalance and bring the pole back to its previous location. Such a reaction does not disrupt the normal rotation (spin). To stop the Earth's spin would take an absolutely enormous amount of energy. Spin simply does not stop.

Let me point out also that the Earth is not a toy top or gyroscope set on a table, and does not react the same way to an impulse. There is absolutely no comparison between a toy gyroscope and a sphere spinning unsupported in space.

A top is subject to a normal force directed up from the bottom, and the force of gravity along the same axis. As you nudge the top, the force acting through its center of gravity is offset from the point of contact at the bottom. This constitutes a couple (a torque) acting permanently around the horizontal center of the top. The reaction torque resulting from this will set the top into precession. And it will be permanent. Nudge it more and it falls over, but since it is spinning, it will turn upside down instead. The top will do this when the force of sliding friction at the point of contact has been overcome. Sliding friction is only ten percent or so of the weight of the top.

You can play all you want, but until you remove the top away from gravity, and off the table, it will not act like Earth under the influence of an external impulse. It would be better to make a comparison to a gyrocompass, which is a gyroscope gimbaled on three axes. It will remain unperturbed when any of the axes are moved.

Data from 1500 BC

Thus the reaction to an external force, as from the sudden repulsive electrical field of another planet, at a distance of maybe millions of miles (see Appendix B, "The Celestial Mechanics"), would be a sweep of the pole through the sky which will make it look as if the Sun is traveling in unexpected ways. The disturbed path of the Sun in 1492 BC was noted in statements from the Mediterranean region that darkness extended over three days, from China that the Sun did not set for three days, and from Mesoamerica that the Sun just showed above the horizon for days on end. Velikovsky suggests that these recollections apply to 1500 BC, and I might agree, for certainly the Earth's orbit increased dramatically at that time.

The Midrashim commentary on Exodus suggests that in 1492 BC the sweep of the pole, "when the stars stopped moving," took a little over a year rather than three days. But it is not certain if the stars were seen at all, and certainly the stars would not relocate, even with an increase in the Earth's orbit. The Egyptian *Ipuwer Papyrus*, apparently written a few months after the initial disruption of 1492 BC, makes no claims for how long a sweep of the pole might have taken, but notes that the seasons were out of order -- which means that the change was noticed within 3 to 6 months. It is also likely that the "change in the seasons" in 1492

was entirely due to the sudden cloud cover which lasted 20 years, plus the removal of the Earth to a much larger orbit.

The repulsive forces which hit the Earth in 1492 BC were experienced in the eastern Pacific, and were followed almost at once by an attractive force which lifted the ocean into the skies. There are no islands left in the eastern Pacific below the equator and west of South America. The population of other islands, as far as Asia were entirely wiped out, leaving only their petroglyphs carved between 10,900 BC and 8347 BC.

I have localized the Earth shock of 1492 BC in the chapter "Moses," and explain the planetary reaction to an external torque in Appendix B, "The Celestial Mechanics." Going by information which can be gleaned from Velikovsky's *Worlds in Collision*, in 1492 BC, before making contact with Venus, it was spring. This is important to know, since it bears on the frozen mammoths, discussed below. Velikovsky claims the 14th of Aviv (equivalent to Nisan, that is, March/ April) as the day of the Earth shock. (Olmec site alignments point to a Gregorian equivalent day of April 19th.)

The sweep of the Earth's axis in 1492 BC followed on a massive earth-shock -- experienced worldwide. This devastating shock was the "event of Exodus," not the parting of the Red Sea waters. The movement of the Earth due to a gyroscopic reaction is not violent. Tsunamis and hurricanes would be due only to the initial reaction to the electrical repulsive force. Earthquakes would be experienced of course, but no landmasses would be subjected to earthquakes or even tremors except in relation to the initial external impulse force, the Earth shock. [\[note 3\]](#)

It is possible that the seasons being out of order might have been due to an actual inversion of the Earth. But the continued gyroscopic reaction would tend to bring the Earth back to its original (upright) position, and rather quicker than the Midrashim commentary that "the stars only stopped moving after a year." It is very conceivable that it would take a long time to move the earth upright again. And there is perhaps no guarantee that the Earth returned to its original inclination. The change to a 30 degree inclination of the rotational axis of the Earth dates from this event, and possibly much of the commentary from antiquity is based on this.

The repulsive electrical shock struck in the west Central Pacific south of the equator. The external torque thus tilted the Earth's northern hemisphere toward the Sun, in effect moving the northern hemisphere into a summer season. Thus summer, not winter, followed spring, but it only lasted some hours or days.

Over the next few hours or days the gyroscopic reaction of the Earth would have caused the spin axis to swing through a loop (in a clockwise direction as seen from above Earth). This would have initially tilted the northern hemisphere away from the Sun, a winter condition, and moved the west faster to the east (at mid-latitudes).

The gyroscopic reaction might have taken a very long time. Or, more likely, the perceived

winter weather might have followed from the water vapor put into the atmosphere as the initial slam, and followed by a lightning strike from Venus which traveled through the Pacific, the Indian Ocean, and into the Mediterranean. The tilt of the Earth was minor, but the impact force was considerable. This was the largest displacement encountered by Earth since 3147 BC.

The change in the radius of the orbit was from 74.1 million miles to 92.1 million miles (119 million to 148 million km). With that change in the orbit the seasons would seem to have changed, for Earth was now 25 percent further from the Sun. Hot summers never returned.

Flipping the Pole in 1500 BC

The following are the suppositions of others. It is thought that if the Earth's spin axis swings through an arc, the crust is just along for the ride, but is impeded by its momentum from rapidly changing direction. The lithosphere would continuously attempt to change direction, following the changing direction of the axis, perhaps sliding over the substrate of magma. The crust, it is further supposed, might not come to rest in the same place relative to the Earth's axis from which it started. This would result in shifts in the geographic location of the North Pole.

Or so it is assumed. The actual movement of the crust might be very little, but even small displacements could cause devastating earthquakes. The gyroscopic reaction torque is exactly what is often placed as the blame: the conversion of momentum from one form to another. But as C. S. Sherrerd, in "Gyroscopic Precession and Celestial Axis Displacement," in *Pensee Journal* (1973), wrote:

"These could occur without large angular decelerating and accelerating forces and without major tectonic disruptions, by the phenomenon of gyroscopic precession. Since gyroscopic precession involves a temporary transfer of angular momentum from spin to precession, when beginning and terminating it moderately affects the rate of rotation of a spinning object and introduces small horizontal forces on points on its surface; but it significantly shifts the absolute orientation of the spin axis in space as long as the precession continues in effect."

The precession, the circular swing of the axis of rotation, will continue until the axis again points to where among the stars it originally pointed, or somewhere near. A large permanent deflection of the pole -- such as turning the world upside down -- is extremely unlikely, for the amount of energy required to do so is enormous. The reaction torque could move the rotational axis of the earth in a circle at or below an equatorial level. But still the Earth would upright itself.

The Earth did not flip over in 1492 but the axis certainly moved through a loop. How long this took we do not know. The data is very sparse. We have only some descriptions which

could be interpreted in differing ways, and one mention in commentaries on Genesis, which could, at any rate, be applied to other repulsive electrical field impulses which Earth has experienced.

Velikovsky attempts to build on the contradictory evidence of the 7th and 8th centuries BC to suggest a 20-degree shift of the North Pole in 1500 BC. Much of his argument is by innuendo, letting the data from the 8th century BC set a tone for an argument about the 16th century BC, augmented by the lack of specifics for 1492 BC. Let me proceed to explore his argument.

He bases the argument for a large shift in the location of the Earth's North Pole in 1500 BC on three items. (1) The fact that northern Siberia has never been glaciated, yet today the region is located within the Arctic Circle and is very cold. (2) The fact that the center of glaciation (actually one of the more recent centers) was located approximately 20 degrees south of the North Pole in an area west of Greenland, which (coincidentally) is almost the current location of the magnetic pole. (3) The fact that large herds of mammoths apparently died very suddenly in Siberia around 1500 BC. I have already addressed two of these issues, but will explore them again briefly. The third will become obvious.

Lack of Glaciation in Siberia

I have suggested that the glaciation had nothing to do with Polar snowfall "extended over millions of years," but was the result of the sudden snowfalls surrounding the strike point of the plasma arc connecting Earth and Saturn. Have any catastrophists ever recognized the obvious?

Between 8347 BC and 3147 BC the arc struck repeatedly in regions well away from the North Pole -- off the coast of Norway, east of Greenland, and in Hudson Bay. [\[note 4\]](#)

The surrounding ring of falling snow had nothing to do with the North Pole. It had to do with the north magnetic pole -- which does not coincide with the geographical North Pole. A compass needle will point to the "magnetic pole." This is located today at 80 degrees north (10 degrees south of the North Pole) and 110 degrees west, a location off the west coast of Greenland. The magnetic pole is a location influenced by magnetic anomalies within the Earth. In 1850 it was located at 70 degrees north (20 degrees south of the North Pole), 100 degrees west. In the Middle Ages of Europe it was located much further north and east, and had been moving south for centuries.

The actual location where compass needles would point straight down is at 85 degrees north and 133 degrees west in AD 2010. This would be the location of a plasma contact, if we were to have a plasma stream contact today.

The north magnetic pole moves in spirals on a daily basis, moves in larger circles over longer

time periods, and since the 16th century has moved southwest, from a location near Spitsbergen east of Greenland (in AD 1590), through the Atlantic, and across Greenland. It is currently moving rapidly north toward the geographic North Pole.

We can draw a 30-degree circle around these points. It will include Greenland, except for the extreme northern part, and at various times also include Northwestern Europe, Canada, and parts of the USA (but not northern Alaska), but Siberia will never fall within the 30-degree radius circle of glaciation.

Frozen Mammoths in 1500 BC

I have also suggested that the Earth changed orbits a number of times since 3147 BC, moving from an orbit much closer to the Sun to our present location thirty percent further away. And I have noted that the largest change in the series of four orbital relocations occurred in 1492 BC.

So here is the "*Tale of the Frozen Mammoths*". It was Spring of 1492 BC (as I mentioned earlier), and the mammoth herds, having overwintered further south in Central Asia, were happily grazing above the arctic circle in Siberia, just as humans had camped and hunted in the upper regions of Siberia since 30,000 BC, when suddenly the weather changed. The Earth's axis swung in a loop and Earth started to move further away from the Sun. The first manifestation moved spring to summer directly, followed at once by winter. It was an arctic winter which suddenly descended on mammoths who normally migrated south in the fall. Although the light returned soon, with this came worldwide hurricanes, followed by an Arctic Ocean tsunami. The mammoths were swept away by winds and flood waters -- or so it is imagined. [\[note 5\]](#)

[Image: A mammoth carving from the wall of the Cave of Font de Gaume, Périgord region, France.]

When the Earth completed its gyroscopic reaction, and summer of the following year came, it never got as warm again as it had in the past, for the Earth had moved much further away from the Sun. The Arctic ground turned to permafrost, a condition which prevails to today.

The mammoths lost.

Velikovsky would suggest that the mammoths died because Siberia suddenly moved north into the Arctic region in 1500 BC -- rather than that the climate changed radically. He holds that some location west of Greenland was the *geographic* North Pole, and as the pole moved from Hudson Bay to its present location in 1500 BC, Siberia would have moved north into the Arctic region, just like Hudson Bay would have moved south.

By that scenario the temples and monuments in Egypt and Mesopotamia which were built before 1500 BC (and after 2600 BC) would face northwest, for that would have been the direction of "north." They do not. Only the Western European megalithic constructions before and shortly after 3100 BC, and Egyptian mastabas and the pyramids until the Meidum pyramid (2600 BC), face northwest -- towards Greenland. In Egypt the change in the orientation of buildings happens after 2600 BC, not after 1500 BC. Since 2600 BC most temples and public buildings are consistently oriented with an axis pointing north or near-north -- the same "north" we experience today. I would thus reject the suggestion that the Earth's axis shifted 20 degrees in 1500 BC.

Other Polar Relocations

The writers Charles Hapgood, C. Rand, Rose Flem-Ath, and Colin Wilson have made much of Antarctica and relocating poles -- with books which are at times listed as "pseudoscientific" in reviews. Hapgood writes of the Earth turning over and ancient maps identifying Antarctica, while Rand and Flem-Ath populate Antarctica with sailors who bring the knowledge of geography to the peoples of the world. [\[note 6\]](#)

I don't take much stock in these theories, although I have fewer problems with Hapgood's map book, especially since his maps show coastal features, without mapping the interior of Antarctica. Rather than being very ancient maps, these coastlines were probably charted by the Chinese naval expeditions of the 15th century, during a period of warm climate everywhere, from AD 800 to AD 1400. [\[note 7\]](#)

I don't buy any of the information in the Rand and Flem-Ath books. The authors hold to the postulate of the catastrophic sinking of Atlantis in 9600 BC, as told by Plato (but not by a single other source in antiquity), and they identify Antarctica as Atlantis (which has not dipped below the waters of an ocean). But of some interest are the identifications of three locations of the "North Pole" based on estimating the center of various previous glaciations. These are placed in the Atlantic off the coast of northern Norway, at the southern tip of Greenland, and at the western edge of Hudson Bay. They also hold that the northern glaciations each form a circle of some 24 degrees surrounding these three locations. [\[note 8\]](#)

At this point, let me summarize the above information: I do not believe that the Earth ever turned over and remained in that position, or that the North Pole relocated by any appreciable amount. Other researchers have proposed, not only that the Earth turned over, but that it remained in that position, until a later gravitational "external torque" of a Mars fly-by, as Martin Sieff notes in "Assyria and the End of the Late Bronze Age" (*SIS Workshop* 1981), in discussing M. G. Reade, "The Ramesside Star Tables" (*SIS Review* 1979).

Endnotes

Note 1 --

Peter Warlow "Geomagnetic reversals?" in *J. Physics*, October 1978. The article notes that spin will not likely stop, however the point of the article is to suggest "pole flipping" while also inducing a transfer of east and west. A summary by others:

"Employing a wide span of data from complex top theory to ancient legend, P. Warlow suggests that the earth has undergone many violent catastrophes, some of them within the time of man. Flood legends, geomagnetic reversals, tektites, paleoclimatology,

salinity crises, and other familiar standbys of the catastrophists force P. Warlow to examine the stability of the earth in the presence of astronomical collisions and near-collisions."

"He shows that the earth rotates slowly and that, even with the stabilizing equatorial bulge, our planet is rather sensitive to outside forces. It is, he says, like ... an 8,000-mile-diameter top that turns over repeatedly in response to external influences. Did not the ancient Egyptians write that the sun once rose in the west?"

This is followed in 1981 by: "Fatal Flaw in Pole-Flipping Theory," *New Scientist*, 92:433, 1981:

"V. Slabinski of the Communications Satellite Corporation claims that there are three separate errors in P. Warlow's theoretical analysis of terrestrial pole-flipping due to the gravitational torques created by a passing celestial body. With these errors corrected, the earth is 200 times less sensitive to pole-flipping. Slabinski does not believe that any known solar system object could turn the earth end-for-end if it passed by. This item proclaims that the discovery of Warlow's errors is a serious blow to Velikovskian catastrophism."

In 2002 William Corliss (of Science Frontiers, Internet) noted: "Over a decade has passed and no rebuttal by Warlow has been seen. We must, therefore, consider his hypothesis highly questionable." In 1982, however, Warlow had countered with a book *Reversing Earth*, noted as "a major scientific contribution" by one reviewer. Warlow has a PhD in physics.

Leroy Ellenberger made the point more clearly when he wrote,

"Warlow's inversion would actually require an intruder 31% more massive than Jupiter, which is patently ludicrous. Adjusting the calculation for a more realistic, and shorter, transit time [Warlow used the application of an exterior torque lasting 24 hours] raises the requirement to a body as massive as 62 Suns!"

-- LE, *Skeptical Inquirer* (1986) with later revisions

Was there anyone who could suggest that the only reason the Tippe-Top (the toy which was used to demonstrate the flipping over of Earth) exhibits its east-west interchange is because the bottom surface would scrape against a flat surface which supported the top while the spin handle (representing the North Pole) dips down to invert the Earth? There would be a spin axis at the top of the wobbling top throughout the inversion, although this is actually the gyroscopic reaction torque.

[Image: The inversion of a Tippy-Top as presented by Peter Warlow.]

Warlow's suggestion of a differential torque applied only to the Earth's equatorial bulge is hardly legitimate mechanics, and only worsens the model. The whole of this Tippy-Top notion is a bad analogy buffered with illegitimate math. It is almost beyond comprehension that since 1978 thousands of academics -- economists, classicists, writers, poets -- have accepted the Tippy-Top analogy without as much as a single thought to the mechanics involved. The debunkers have the same nearsightedness, offering solutions that are simply not required.

What Warlow understood in looking at the spinning Tippy-Top is that the original vertical spin axis remained in place at the top of the Tippy-Top, even as the original spin handle dipped down and started to precess. But this is not so. It is indeed difficult to tell what is happening with a spinning top.

The original spin remains at the spin handle, even as this dips down and starts to precess. When the spin handle starts to lean over a gyroscopic reaction torque is added, exhibited as a rotation in the same direction as the original spin. The axis of this is located at the top of the Tippy-Top by the time the spin handle is horizontal.

The gyroscopic reaction torque results from the couple which forces the top's spin handle down. This couple (torque) is produced by the down-directed force of gravity and the up-directed normal force at the base of the Tippy-Top where it is in contact with its supporting surface. As the Tippy-Top inverts completely, this couple disappears, and the spin of the gyroscopic reaction torque has substituted for the original spin -- and in the opposite direction.

The Tippy-Top will indeed reverse direction. The Earth would too, if it could be placed on the surface of a table.

Note 2 --

Velikovsky supplies some additional data on water clocks and shadow clocks in Egypt built before 750 BC which no longer record the correct daylight hours at solstice. Since shadow clocks can easily keep time to within a few seconds, and have done so since antiquity, this is a notable anomaly. The data he presents, however, is entirely inconclusive, or missing.

Note 4 --

As noted in another chapter, the orientation of European megalithic structures, the orientation of the first Egyptian mastabas and pyramids, and the direction of the World Mountain in Chinese mythology all intersect at the Atlantic south of Greenland. This was the location of the last strike point of the Saturnian arc, and the north magnetic pole in the period before 3147 BC. Today it is west of Greenland.

[\[return to text\]](#)

Note 5 --

There are two-hundred-foot-high piles of mammoth bones and tusks (and elephants and other Asiatic grazing animals) on the shores of the New Siberian Islands, swept to land (it is assumed) by Arctic Ocean storms. Most of the ivory of antiquity came from this location.

The whole question of why the mammoth died out in Siberia, Asia, Europe, and the Americas has been in contention for a hundred years. Carbon-14 dates are often brought forward as evidence of an antiquity stretching to 30,000 BC, but the same carcasses will have stomach contents dated to 1500 BC. See Charles Ginenthal *Extinction of the Mammoth* (1997).

What is clear is that the mammoth (and many other diverse species) lived in..

"... a grassland environment with a long growing season, mild winters, very little permafrost, and a wide diversity of plants -- quite different from the climate in the region today."

-- Michael J. Oard, in "The extinction of the woolly mammoth: was it a quick freeze?"
<http://AnswersinGenesis.org> (pdf, 1997)

Mammoths not only ate grasses, but whole bushes and small shrubs. Oard also notes two interesting facts. First, many mammoth carcasses show signs of asphyxiation, and, second, most remains are found in windblown deposits (at times in a standing position). They did not slip into bogs, as some people maintain.

The mass extinction of the mammoth, especially in Siberia, has been taken up by Creationists (including Michael Oard, above) as a *cause célèbre*, and is as a result mired in pseudo-science, with similarly muddled objections from Gradualists.

Note 6 --

A few reviews posted at Amazon.com:

Charles Hapgood *Maps of the Ancient Sea Kings* (pb 1997):

Eric Vertommen (Brussels, Belgium) "*Charles Hapgood has made an excellent job to point out some strange features on Ancient maps. Comparing a set of maps made from Ptolemaea (166 AD) to the Middle Ages and the first global maps made by Piri Re'is (An Ottoman admiral), Hadji Ahmed, Oronteaus Finaeus, and Mercator, all editing their maps between 1513 and 1560, he (and the reader) notice that Antarctic continent figures almost accurately on all of them.*"

C. Rand and Colin Wilson *The Atlantis Blueprint* (2002):

From Publishers Weekly: *"In this pseudoscientific account, Flem-Ath, a Canadian librarian, and Wilson, bestselling author and New Age jack-of-all-trades, propose a single, geo-historical theory that links the Egyptian, Chinese and South American pyramids and other sacred sites. According to this argument, these civilizations received templates from Atlantis that contained crucial geodesic, geological and geometric information. Furthermore, Atlantean mariners, based in Antarctica, sailed the globe over 100,000 years ago and established more than 60 sacred sites around the world, such as Byblos and Jericho, to preserve the sophisticated wisdom of their culture. (Copyright 2001 Cahners Business Information, Inc.)"*

C. Rand and Rose Flem-Ath *When the Sky Fell, in Search of Atlantis* (pb 1997):

"The mystery of Atlantis, the legendary advanced civilization described in ancient texts, has been solved at last. Scientific evidence, exciting new research, and the breakthrough discovery of an amazing Egyptian map prove without a doubt that this lost continent did exist ... and reveal where its ruins can be found."

See also Charles Hapgood *The Path of the Pole* (1999). I fail to see what "geodesic information" or "sophisticated wisdom" would have been so crucial. Antarctica has been glaciated for over 30 million years. A number of people have completely dismissed the Piri Re's map. See, for example, the comments of geologist Steven Dutch, "The Piri Reis Map" at [\[www.uwgb.edu/DutchS/PSEUDOSC/PiriRies.HTM\]](http://www.uwgb.edu/DutchS/PSEUDOSC/PiriRies.HTM).
[\[return to text\]](#)

Note 7 --

This is the point of research by Gavin Menzies, in *1421: The Year China Discovered America* (2002). Menzies includes the circumnavigation of Greenland in addition to Antarctic explorations. The ice-free coasts did not last, for by the time the Europeans started worldwide explorations the Atlantic had become very stormy. The last climatic changes are as follows: circa 500 AD: warm; circa 800 AD: cold; circa 1400: warm; circa 1700: cold.

Of course Menzies's maps are disputed, as is his whole thesis. But if we allow that climatic condition were not always as they are today, then the settlement of South America and South Africa by Cro-Magnon humans via Australia and the very productive fishing grounds of Antarctica becomes a real possibility, even if placed 60,000 years ago in time.

[\[return to text\]](#)

Note 8 --

Rand and Flem-Ath place the center of the European glaciation at 73 degrees north and 170 degrees west, and give no dates; place the Wisconsin glaciation at 63 degrees north and 45 degrees east, starting at 2.5 million years ago and ending about 100,000 BC; and place the Illinoian glaciation at 60 degrees north and 97 degrees east (the east end of Hudson Bay),

ending in Plato's date of 9600 BC. This last is far too late. The last ice age came to an end in 12,000 BC. I'm not at all in agreement on the locations either.

Contents of this appendix:

[\[The Palette of Narmer\]](#) [\[Endnotes\]](#)

The Palette of Narmer and the Predynastic Kings of Egypt

Predynastic Egypt includes the time from perhaps 5000 BC to about 3050 BC, or at least to before the first dynasties. Egypt has been better studied than other areas of the world because of our continued fascination with Egypt, but also because Egypt presents a long continuity of culture within a limited geography, and, by good fortune, a desert soil which preserves archaeological remains well.

I have stated that there was no civil leadership during the "Era of the Gods," something claimed by many archaeologists and based on the absence of graves endowed with surplus "grave goods." But this is not entirely certain, for archaeologists frequently date some elaborate graves to before 3147 BC, both in Mesopotamia and Egypt. These finds may suffer from difficulties in dating, but also cannot of necessity be ascribed to "kings" or "pharaohs."

Since the temple culture in Egypt, as elsewhere, certainly predates the end of the "Era of the Gods," there would have been priests and, as the temple culture expanded, assistants to priests and, as a result, a hierarchy. This might have been enough to honor those in charge upon their death, and might explain the companions which followed them to the grave. In actuality we know next to nothing of the circumstances for elaborate graves -- especially since all were robbed in antiquity. Archaeologists, however, have identified a series of "kings" who preceded the First Dynasty of Egypt. But let's first see what the Egyptians themselves say.

Manetho (300 BC) identifies the first king of the first Dynasty as "Menes" in his list of kings of Egypt. Menes, says Manetho, unified Egypt, that is, he forged it into a single state stretching from Nubia to the Mediterranean. The unification has always been held as the unification of Upper Egypt, south of the Nile delta, and Lower Egypt, the delta region.

Herodotus, 100 years earlier, wrote the same, based on information gathered from the priests of Sais. Actually, in more correct terms, Menes unified the upper and lower land -- heaven and Earth.

What is important in the parallel information supplied by Herodotus and Manetho, is that there clearly were temple records dating back nearly 3000 years to the First Dynasty. These seemed to have been canonical, for the records change almost not at all over this long period of time. The first instances of a consecutive listing of kings are one or two lists of the serekhs of the kings of the First Dynasty, found in First Dynasty graves (3050 to 2857 BC) at Abydos.

A second instance is 300 years later. It is a carved basalt block from the Fifth Dynasty of the Old Kingdom (circa 2550 BC), the Palermo Stone: unfortunately shattered, badly worn, and reduced to a few fragments. The Palermo Stone lists the Gods, the "Followers of Horus," and presents a partial list of the pharaohs of the first five dynasties. For each of the pharaohs the Palermo Stone lists a catalog of important events, year by year, although most of these events are as mundane as the acquisition of lumber or honey, the dedication of a statue, or a national cattle census.

A last significant listing is a papyrus dating supposedly from 1200 BC, the *Turin Canon*, which also lists the Gods, some three groups of mythical spirits and kings (with "lifetimes" spanning many thousands of years), and then, in the same order, the pharaohs and their reign lengths, starting with Menes, who is listed twice in succession, once with the glyph for a God and the second time as a mere human. "Menes" means "who remains" or "endures" -- suggesting that Menes is to be identified with Jupiter, and thus Abraham. But there is more. [\[note 1\]](#)

The listed reign lengths of the *Turin Canon* are much longer than archaeological evidence indicates. Manetho may have had much more realistic reign lengths available to him, but he also lists the Gods and the demigods at exceptionally long lifetimes. There are additionally temple inscriptions of later dates which at least largely follow the same sequence.

Who came before Menes, is a series of persons or spirits, called the "Followers of Horus," and before that time lived the Gods. Nine of them, all easily identifiable both from ancient records (the Palermo Stone) and from much later records (like the *Turin Canon*). There are no records of kings before Menes of the first dynasty. There are, in fact, no records of Menes besides mention of being the first king.

The Palette of Narmer

Archaeologists have been concerned with the social and political history of Egypt, and have traced cultural development from 4500 BC. By 3100 or 3000 BC the culture of Egypt is uniform from Aswan to the delta. Unification of Egypt was claimed for Menes (circa 3050

BC), and obviously would have been an expansion of cultural or religious elements of Upper Egypt into the delta.

But at the time of Menes the delta was seriously flooded from the higher sea levels after the flood of 3147 BC. Herodotus claimed, on the basis of information from the Egyptian priests, that the delta was indeed flooded, and that land reclamation was attributed to Menes. There was thus hardly any need for Upper Egypt to conquer Lower Egypt. But Herodotus has been ignored on the matter of a flooded delta. Who would believe in a world flood anyway?

Image: The Palette of Narmer, circa 3050 BC; left: front face. After Francesco Raffaele.

Since there is a theme of "unification" repeated over and over again in Egyptian history, it suggested (to archaeologists) that the conquest of the delta by forces from Upper Egypt must have been a monumental event. We know absolutely nothing about Menes, other than an indication that his name means "he who remains." The name of the founding king of the first dynasty is also missing from the Palermo Stone, and is recorded differently from "Menes" in other records. Since there is also no evidence of battles or conquests during this time, that is, at the time of the beginning of the First Dynasty, archaeologists were determined to find this event at an earlier time.

The outstanding example for a suggestion of an early unification of Egypt is attributed to a predynastic king named "Narmer" who has even been equated with Manetho's first pharaoh, "Menes." The suggestion for a king named "Narmer" comes from the "Palette of Narmer" found buried below the floor of the temple at Heirakonpolis (Nekhen, the City of the Falcon), in Central Upper Egypt, and dated to 3000 or 3050 BC by inference from other known cosmetic palettes. [\[note 2\]](#)

Image: The Palette of Narmer, circa 3050 BC; detail of top register of front face. After Francesco Raffaele.

It has been suggested that this palette represents a victory commemoration for the unification of Upper and Lower Egypt. Narmer was thought to be Menes, who left no other record. Unification became such an important "theme" for all the later pharaohs, that archaeologists could not help but suggest that this must have happened in the pre-dynastic era, for there is no mention or evidence of warfare during the First Dynasty.

I think the Palette of Narmer depicts not a person, but most likely Jupiter -- he who remained -- shown in the last celestial battle. The dress and insignias, however, make him Horus of the Egyptians -- the planet that descended to Earth repeatedly in the previous 1000 years. The imagery dates from long before the breakup of the Polar Configuration, and it is used here perhaps because there was no available theology for the present condition, and as a result the associated imagery is missing. This is a somewhat radical position to take for me, but it is demanded on the basis of the strength of all the prior text of this website.

The image on the reverse of the palette, showing Horus braining Uranus had been in use as ivory grave-goods labels for 300 years or more. The palette therefore presents familiar imagery.

I have looked at the progression of palettes from Naqada through pre-dynastic times. The questions of serpopards and giraffes and matched palm trees are adequately answered by the images in the sky at the north horizon during the period up to 3147 BC. (There is a Gebel Tarif knife handle, and some other predynastic knife handles, which show the "serpopards" as snakes instead.) But let me just introduce what is going on here.

First, though, I should make the point that Egyptian representational graphics are not narrative. They are situational, and we could presume that they are without reference of the passage of time or to causal connections. We, of course, demand a narrative in any collection

of images. We make up sequences of actions even if none are intended. I have seen any number of serious attempts by academically accredited researchers at a sequential reading of the Narmer Palette, which involved switching registers and flipping from front to back to make sense of the imagery. But if there is an implied sequence meant for reading, it is as yet hidden from us.

... the front

The palette can be read, and probably in the following order: front face first, back next. The front face (called the obverse) is the side with the circular depression used for grinding cosmetic powders. I would suggest also that the individual registers need to be read from the bottom to the top, and each generally from the left to the right. Reading from left to right is based on other Egyptian inscriptions which are always meant to be read in the direction which the animals or the people of the glyphs face.

On the front face, from the bottom, we first see the Bull of Heaven smashing the walled City of the Gods. Jupiter was seen as the approach of a bull, with his upper horns above and his huge bulk below. The shock of the electric field force between Jupiter and the Saturnian planets, once their plasmaspheres intersected, resulted in the dispersal of the planets traveling with Saturn. Earth was released from Saturn in the process. This also released the standing ocean waters from the South Pole.

Egypt was largely unaffected by the flood of 3147 BC, so that, instead of seeing Noah's ship landed on a mountain, the Egyptians saw the crescent on top of a giant outpouring of plasma from the underside of Jupiter's coma as his horns. Jupiter would have been in the direction of the Sun; Earth was well below Saturn and Jupiter.

The bull is not a representation of the pharaoh; it is Jupiter, the "bull of heaven." The city with the broken walls is the original home of the gods where the satellites of Saturn resided as gods. The dead person therefore is Saturn. We can be assured also that any naked persons (or gods) are dead.

There are hieroglyphic labels, but most cannot be read. They are too early in the developing Egyptian script, even if borrowed from Mesopotamia. Either way, most are unrecognized. What has been suggested in this case for the dead Saturn is a label ("styw") translated to mean "Asiatic" or "Easterner." Since the approach of Jupiter, headed for an interaction, would be seen from Earth as coming from the west, the Easterners here must be the resident satellites of Saturn.

In the next register are the serpopards (as they are known). This is an image of the plasma dome near Earth (the bulky bottom portion), with two polar plasma streams above. The plasma streams are in high level glow mode, which forces them to twist around each other. Archaeologists feel that the two human figures are looping the long necks of the serpopards.

But it is much more likely that the serpopards are being separated in order to be removed. This could be an action image, but just as likely it represents the status over the last 1000 years.

In the top register, from left to right, are Horus followed by his sandal bearer son, and preceded by a priest and four standard bearers -- or so it is thought to be. They are about to view ten decapitated and castrated captives.

That is not his son, but Mercury. He carries two sandals, and a jar of oil (it is assumed). There is an insignia around his neck which is unreadable. Archaeologists think that it is replicated in the rectangular window behind him. (Not so on the reverse side.) Others claim this image is a boomerang (boomerangs occur worldwide). As a boomerang the glyph is read either as "guard" or "running forth" or, if I may add my two cents, as "returning." Mercury also has a six pointed star as a label. This is a Mesopotamian glyph which designates him as a god or royalty. With a bald head he would be a god.

Mercury is a gigantic winged bird, seen simultaneously with Mars during this era, not the seated falcon of much earlier times. Mercury had polar plumes, one pointing up (to the north) and one pointing down (to the south). Mercury would move from east to west across the sky as the Earth rotated to the east.

Horus is shown with his nighttime crown, the insignia of Lower Egypt -- which signifies Earth, as opposed to heaven -- and which will become the crown representing Lower Egypt, that is, the delta. Part of the front of the palette seems to record the event of 3147 BC which happened in the north, but the parade of the top register has to be assigned to the view of the south.

The pharaoh's name is engraved directly in front of him as "catfish, chisel." The same insignia is also presented in the center at the top of both sides of the palette in a serekh.

The dress and paraphernalia of the king is Egyptian -- a fake beard, a bull's tail from his belt, the short kilt with the over-the-shoulder strap. The pharaoh carries a flail in his right hand, and a cudgel in the other. At a later time this will be exchanged for a curved staff. Perhaps at this time very little had been seen of polar plasma plumes, although the sculptures at Palenque give a time span of 18 months before the first polar plume appears. The polar plume is the model for the staff carried in death by the pharaohs, designating control over infinite time. The depiction of the regalia remains the same for the next three thousand years.

There are additional decidedly Mesopotamian elements, primarily in the hieroglyphs used to identify the figures, including the "serekh" sign used to indicate the name of the king, "catfish-drill," which has the sound of "Nar-Mer." The pronunciation of this rebus is distinctly Egyptian. But the remaining script is claimed by some to be from the syllabary of northern Mesopotamia or Anatolia, dated to the Jemdet Nasr period (3100 to 3000 BC).

[\[note 3\]](#)

The sign of the "serekh" is the facade of a temple, enclosed in a rectangle, a symbol the Egyptians will retain, whereas it will be abandoned in Mesopotamia. The serekh is used at the top of both sides of the palette. The later Mesopotamian "temple" is a round-roofed thatched hut, still in use today in the region between the Euphrates and Tigris south of Baghdad. The Egyptians built with different materials, and their serekh symbol is a rectangular building with fluted walls.

Image: Sumerian Temple Hut. After history-world.org.

In front of Horus is a wigged person with a smooth face. This is generally thought to represent a priest or another son of the pharaoh. A few researchers have overcome their biases and have suggested it is a woman. The question remains, What is she carrying? It looks like a bola.

The name glyph (a rope tie and a bread loaf) reads "t't" which much later came to mean vizier. This could represent Venus, which from the earliest times in the Eastern Mediterranean has been held to be female. Venus had escaped from the destruction by Jupiter.

The parade is led by four standard bearers, often suggested to represent defeated delta nomes, even if it remains that there are 16 others which are not shown. The raised standards are not defeated nomes, as suggested by some archaeologists, but represent the four cardinal directions. The standards are depicted again in other artifacts from this time, still four of them (one later monumental depiction uses five). But there are some 20 nomes in the delta region and another 20 in Upper Egypt. The standards are not conquered nomes.

The stomach depicts the south. It is an image of the southern plasmoid, as it also is the glyph for "king" in Mesopotamia.

North is depicted by the "dog" (actually a jackal) on a plow, where the plow is Ursa Minor. Before the center of rotation of the Earth changed location in the dome of the stars, Ursa Minor rotated around the pole of Ursa Major. This depiction will remain in use for the next 3000 years, as for example at the ceiling design of the temple at Denderah.

The hawks on bannered standards are the east and west direction, the locations between which the seated hawk "Horus" (as the Saturnian group of planets) traveled for 4000 years. The same banners are depicted somewhat later in Mesopotamia, but with circles on top rather than falcons.

The ten dead men are next, arrayed with their heads between their legs. Above the dead men is a line of hieroglyphs, which reads from right to left (thus backwards). Louis A. Waddell reads this as "*Magan, dead men*" [or dead birds]. This makes little sense.

The alternative reading for the glyphs is, from right to left, "the bark of Horus," where a falcon is sitting on a harpoon above the ship, suggesting a reading of "only Horus." The ship has the usual covered hut, plus what looks like the head of a bull and some other object. In front of the ship is a swinging door and another Horus falcon, which could read as "the Horus gate."

It would seem that these might represent the "followers of Horus," appearing toward the west before Horus showed up in the night sky. But there are too many. The phrase "gate of Horus" may be the opening and closing of the gap in the Absu at the time of the equinoxes. It is from there that Horus would regularly appear. This would have happened every year and a half. Interestingly, the archaeological date of 3050 BC is after my estimate of the first return of Mars in 3067 BC.

... the back

The reverse side has only two panels. The bottom register shows two dead men -- perhaps the Gods Uranus and Neptune. Uranus is identified with a name label of a city plan with crenellated walls. The other planet by association has to be Neptune. Its name hieroglyph looks like a rope knot.

The upper planet of the 3147 BC confrontation was Uranus. He is shown in the second register, being brained by Horus wielding Venus as a club. Horus is here holding him by his long hair. This has happened thousands of years earlier. Horus wears the daytime crown of Upper Egypt (heaven), and, like on the obverse side, the kilt, bull's tail, and fake beard. He also wears an apron decorated with four bull's heads. (On the obverse he wears a net and a sack from the waist.)

Uranus is not shown with long hair as is typical of almost all the other "Smiting the Enemy" tableaux, throughout 3000 years of Egyptian history. The "smiting" image had been in use already as ivory labels for 300 years before the assumed date (3050 BC) of the Narmer Palette. The image has shown up also in the Levant and Anatolia. So perhaps the image is not strictly Egyptian, although it continues in Egyptian use for three thousand more years.

The image of the pharaoh as Horus/Mars, with his mace and captive, represent a combination

of elements originally assigned to Mars in its repeated descents to Earth from Saturn before 3147 BC.

The Maya *Chilam Balam* describes Saturn, the primary god known as the Thirteen, and his devices. The club is Venus with its trailing plasma connection to Saturn. The "enemy" held by the hair is Uranus -- grabbed either at the time of the dissolution of the polar configuration in 3147 BC, or at a much earlier time when Uranus sank from view above Saturn -- a thousand years earlier. This image is related directly to a view of the north horizon.

Uranus is labeled with the hieroglyphs for an harpoon and a lake. It is suggested by others that this represents the concept of "unique" or "the only one." This is taken by others to translate to "Angra Mainyu" (Malign Mind), which is a Zoroastrian construct (and thus two thousand years later), representing the evil aspect of a god -- the devil -- Ahriman in Persian.

Horus is followed by Mercury bearing his sandals, as on the obverse side, but without the "guard" boomerang symbol. Again, he is bald and shaven and accompanied with the 7-pointed star symbol of a deity (on the reverse the star is 6 pointed).

To the right of Horus, and facing him, is a large falcon seated with one leg on a set of six papyrus buds while in his other claw (hand) he holds a rope leading through the nose plenum of a human head. The head is attached to a shape which normally would designate a lake or body of water from which the above mentioned papyrus buds sprout. Others have seen this as a sign for captives taken in the swamps of the delta, but the really large swamp is the Duat in the south sky. It has also been suggested that each papyrus stem stands for 1000 prisoners.

These again are, I would surmise, the "Followers of Horus." I have covered the concepts of the Followers of Horus, and the Maruts, in detail in Chapter 18. I count the "Followers of Horus" as six.

One last element is to address the bull-horned faces at the top corners of both sides of the palette. These bulls are thought to represent the goddess Bat, who represented the entire cosmos, and later show up as Hathor with the same bovine ears, but without the horns -- except as part of her headdress.

... concepts

The palette represents the earlier Saturn (actually Horus, as shown by the Horus crown) wielding Venus as a club and about to bash Uranus who has been grabbed by his hair. It is used here to name the winner of the last battle, waged between Jupiter and Saturn. It does not depict the battle, for it is a static image from recent antiquity -- decades before 3050 BC. If a battle is suggested, it would be between Upper Earth and Lower Earth, a battle between Jupiter and the Titans, a battle waged before these planets reaching the asteroid belt. The two regions of Heaven (Upper Earth) and Earth (Lower Earth) were equated with Upper Egypt

and Lower Egypt by later dynastic times, and, I suspect, certainly by the time of the third dynasty, after about 2686 BC.

But of course the palette is about Narmer the conquering Catfish Chisel, the Bull of Heaven, and represents Jupiter, although on both sides parading as Horus. This may have been the only allowed image available. It is strange also that the planets are depicted as persons.

I seriously doubt if the palette of Narmer has anything to do with local warfare. We think in terms of action and causal relationships. The meanings of Egyptian images are, I suspect, mostly beyond our ken. They are most likely totally religious. They are sacred depictions of beliefs of 5000 years ago, and incorporating beliefs dating back to the earliest encounters within memory with Saturn, probably at about 11,000 BC. Dead animals traveling through the skies date from 30,000 years ago.

At the time of the Narmer Palette and Menes (Jupiter), Egypt was already united culturally with the establishment of the city of Memphis at the neck of the Nile delta (attributed to Menes). The Upper Egyptian Horus became the name of the God who ruled Egypt, and the pharaohs became Horus. But Horus was Saturn originally, and Jupiter later. During the period of the Palette of Narmer, Horus was Mars.

Having a single king recognized as God himself, perhaps in his function as chief priest, or having someone assigned to play the role of God, must have solved a lot of administrative problems in the acquisition and distribution of temple products. After the time of Menes, the "Followers of Horus" are still mentioned on the Palermo Stone, and in a few instances as late as the 5th dynasty, 500 years later. But the "Followers of Horus" never enter funeral ceremonies.

"No God has walked on Earth as a man since the first pharaoh," the priests told Herodotus (paraphrased). Narmer and the "Followers of Horus" are thereby dismissed. It is only the later pharaohs who counted. The First Dynasty is based on a theology of "unification" of Upper and Lower Earth, applied to the land of Egypt, where a pharaohic "unification" of the country continues to be celebrated, appropriately so, for the pharaoh was the God Horus. Whenever celestial events threatened a disruption -- as with the regular overflights by Mars from 3067 BC to circa 2700 BC -- it is the pharaoh who settles the matter with the "Upper Land" and the "Lower Land" and announces that the "two lands are at peace" again. Manetho mentions some large disasters during the First Dynasty ("there were many portents and a great calamity") and again during the second ("a chasm opened at Bubastis"). Archaeologists have noted that many early monuments and graves were destroyed by intense fires.

What we think of as pre-dynastic kings -- Narmer, Scorpion, and Crocodile -- are celestial apparitions, certainly the disturbed dust and objects in plasma discharge in the asteroid belt as Jupiter and Saturn moved through. They were the last of the battle between Heaven and Earth. As recorded by the later Ennead of Heliopolis, Osiris was stung by a scorpion during the battle. The Egyptians never again mentioned Narmer, or the names of other predynastic

kings, despite the fact that Narmer's serekh has been inscribed widely -- from Anatolia to the Sinai. It was a theology in flux, which settled upon a new form shortly before the first dynasty.

The strongest argument against Narmer, or Catfish, Scorpion, Crocodile, and the other, being human kings, is that not a single mention of any of these is forthcoming from all of later Egyptian records, legends, and histories.

Francesco Raffaele, in "Ancient Egypt: Dynasty Zero" (2002), writes:

"Narmer palette, once considered one of the key sources attesting the 'Unification' of Upper and Lower Egypt by this king, is now almost completely dismissed as a proof for such an event, and tendentially removed from discussions about Unification. Scholars now tend to look at this important object as a memorial of a military victory or as a ritual object reinforcing the role of the king through the depiction of a scene (which not necessarily happened in Narmer's reign) which was part of an already well formed iconography and ideology of kingship."

-- <http://xoomer.virgillio.it/francescoraf/>

But of course Raffaele continues to hold Narmer as a person. The Palette of Narmer is a complete depiction of the Saturnian polar apparition on the back side, and its destruction on the front side. The pharaoh is Saturn on the back, Jupiter or Mars on the front. His crown is that of Mars as Horus, his club is Venus attached with a plasma stream, and the captive is the long-haired planet Uranus, visually seen "below," but in actuality already long dead. Uranus had not been seen in a thousand years.

Endnotes

Note 1 --

Both the Palermo Stone of 2550 BC and the later *Turin Canon* list Horus and a second Horus. The first Horus is also called "Horus of the Gods" and is probably Mars before 3147 BC; the second Horus is the resurrected Osiris, which might have been Jupiter initially, but if so, the name was soon transferred to Mars. ("Horus" is equivalent to "Lord.") A much later (third) "Horus the Child" shows up after 747 BC.

The *Turin Canon* is a damaged papyrus document of uncertain date (estimated at 1200 BC) which was recycled in antiquity. The back of the document holds accounting records; on the front is a list of all the kings and pharaohs of Egypt, as if it is a school exercise. The Papyrus starts with a list of the primary deities. Most of the reign lengths are broken off the original papyrus, except for Geb, 744 years, Horus at 300 years, and Thoth at 3126 years. A number

of temple inscriptions provide nearly the same information (that is, the order), as does the Palermo stone.

Geb is the God of Earth, and thus associated with creation. But most likely Geb represents the "land" in the sky, not the Earth, which is also why he can be assigned a finite reign. The reign of 744 years matches the span of 720 years for Alorus, the king who does not descend to Earth, of the "kings before the flood." Others, including Manetho, have equated Geb with Kronos, that is, Saturn. Since Geb is intimately involved in the creation of all the Gods, it is as likely that Geb represents the south polar ball plasmoids of 10,900 BC to 8347 BC.

Geb's main function was to impregnate the Goddess Nut, who, at a later date comes to represent the black night sky. Nut gives birth to the first Gods. Geb is always depicted on his back with a giant erect penis, while the Goddess Nut arches across the space above him, touching the horizon with her fingers and toes. Nut has all the looks of the arch of the Duat (she is also depicted as the celestial cow, and called "coverer of the sky"). The plasma streams of the Peratt column, which passed by Earth, connected the plasmoid in the south with some amorphous shape in the north. With the streams appearing intermittently, the image of copulation is complete.

In the *Turin Canon* Thoth is given a reign of 3126 years. If Thoth, as Mercury, lasted at least to 1200 BC, the date of the *Turin Canon*, then his birth would date to about 4300 BC. A date of 4219 BC was my initial estimate of the time when Saturn went nova (I later revised the date to 4077 BC, which would place the writing of the Turin Papyrus in 951 BC (4077 - 3126 = 951). As the coma disappeared all the companion planets of Saturn would show clearly at that time. That means Thoth was first identified at the beginning of the "Era of the Gods." Ra or Re, however, should have had a much longer lifespan, except that he was officially known to have "retired" sometime after the flood of 2349 BC. Of course in this instance Ra is Jupiter, not Saturn.

[\[return to text\]](#)

Note 2 --

If Mars and Mercury returned in 3067 BC, then I would place the creation of the Narmer Palette in this year or later, since Mercury attends the procession depicted on the palette. That suggests that the pharaoh figure is Horus/Mars. Then the Narmer palette is about the appearance of Horus and Thoth, not about a celestial entity which fires plasmoid lightning bolts. This last would not have been Mars or Mercury, but Jupiter.

[\[return to text\]](#)

Note 3 --

Louis A. Waddell, in *Egyptian Civilization, Its Sumerian origin & Real Chronology And Sumerian origin of Egyptian Hieroglyphs* (1933), claims that the Palette shows upper Mesopotamian pre-cuneiform script incorporated into the four standards carried before the

figure of the Red Crowned pharaoh -- a placenta, a dog, and the two falcons. Others have suggested that these were the standards of defeated nomes, but this is as conjectural as Waddell's claims. Waddell reads the marks on the standards (in an almost microscopic script) from left to right as *"of the land of Uri and Kish city, the one king"* (the placenta shape is the Sumerian "lugal" -- king), *"of the western sunset land and of Tianu"* (Tianu is Syria and coastal Levant), *"the king of the lands and waters, the hawk"*, and last, *"the great sea-lord, the hawk."*

Deep Space 1 finds Comet Borrelly has [a] hot, dry surface.

"The spectrum suggests that the surface is hot and dry. It is surprising that we saw no traces of water ice," said Dr. Laurence Soderblom of the U.S. Geological Survey. *"We know the ice is there,"* he said. *"It's just well hidden."*

-- NASA/JPL NEWS RELEASE April 7, 2002

Deep Impact

For readers unfamiliar with the contact between the space probe "Deep Impact" and the comet "Tempel 1" which happened on July 4, 2005, here is a replay.

The idea was to hit a comet with something massive, to see if comets really were "snowballs" -- as was suggested 60 years ago by Fred Whipple who coined the phrase "dirty snowball." The comets have been held to be distinct from asteroids and meteors (they are not), because there was no accounting for all the water on Earth without some extraterrestrial delivery system. After all, other planets and moons have no water or very little water. Earth has a lot. Only comets, on their wild orbits, could actually reach Earth.

Additionally, it was assumed that the enormous tails of comets must be ice sublimating to water vapor due to the heating of the Sun (the sunward side of a comet may reach a temperature of over a hundred degrees Fahrenheit). This theory reached conviction when hydroxyl (OH) molecules were identified in the tails of comets, and remained in vogue even after it was recognized that the Solar Wind which shaped the glowing coma and tails of comets -- the long stretched-out streamers -- produced them by combining Solar Wind protons (H⁺) with cometary Oxygen (O⁻) ions released from silicates.

Comets were also held to be "dirty," that is, covered by dust, because a comet consisting of

ice or snow would reflect sunlight, and the icy material would never sublimate to form a tail millions of miles long.

[Image: Comet Tempel 1 moments after impact by the probe from the spacecraft Deep Impact, July 4th, 2005. After NASA.]

All of this consists of a picture drawn by an eight year-old. The comets become bottle rockets leaving smoke trails in space -- at times 100 million miles long (the largest objects in the Solar System), coming from an icy object less than a few miles across. At times there are dual tails, spikes pointing toward the Sun, tails moving away at right angles from the main body, and curved horns at the front. But most of these other displays have been neglected. How could a comet a few miles across form a coma as large as the diameter of the Sun -- 864,000 miles -- and a tail longer than the distance from the Sun to Earth?

There is obviously something wrong with this description. What is even more wrong is the conviction that comets represent the coagulation of the dust of the primordial Solar System, and that these represent the formation of a planet or planets which had gone wrong.

Never mind all the contrary data, the space probe "Deep Impact" was going to close in on the comet "Tempel 1," fire a 800-pound copper projectile at some 35,000 miles per hour, and record the sequence of events both from a camera mounted on the projectile and from the spacecraft "Deep Impact" passing by at a safe distance of some 800 km. It was fully expected that the projectile would penetrate the comet, or would start a new "sublimation" point which would gush water vapor into space for the next 1000 years.

Neither happened. In fact, nothing happened to any expectations, and the community of researchers was left scrambling for new theories.

Only a few people made correct predictions. They were based on very simple concepts: (1) comets are rocks, and (2) the interactions would be electrical.

Predictions

My Predictions

I made some predictions, first in March of 2005, when I became aware of the Deep Impact mission, which I posted somewhere on my site on July 3, 2005. I predicted that at best only a small crater would be made. NASA expects a crater the size of a football stadium, over 150 feet (50 meters) deep and 250 feet (85 meters) in diameter. I also predicted that most likely the disturbance of the comet's electrical field by the approaching probe would cause an inrush of electrons speeding ahead of the arrival of the probe, **causing an explosive arc at the impact location well before the probe arrived, as a sudden lightning stroke from the comet to the probe**, ending in a brilliant green flash as 800 pounds of copper were vaporized.

Nothing quite as spectacular as the green flash happened, although the predicted pre-contact flash happened. **Thornhill predicted the same thing** (not the *green* flash) a day or two later, on July 5th. I do not need to claim primacy, however, because the flash would be completely predictable from an electrical standpoint.

Thornhill rightfully took some pride in predicting the pre-contact flash, and the world's media descended on him in the week after the mission. But as soon as he was identified as a Velikovsky follower, all interest evaporated, and the media packed up. This may have turned Thornhill from ever again wanting to be associated with the name of Velikovsky. But here also was a missed opportunity, for to have been able to tell the media that what happened was so obvious that any number of electrical engineers, physicists, or astronomers would have arrived at the same conclusion. This would have ameliorated the Velikovsky contamination.

I should also point out that a brilliant object in space traveling toward a spaceship had happened before. I recall an incident where a spacecraft, on approaching a moon (a planetary satellite), recorded what looked like a missile traveling at high speed from the moon. The space ship lost radio contact a second later. I need to find the source for this.

I wrote:

"Let me hedge my bets: If the probe makes contact with the comet, that is, if it makes a splashdown, it will provide a large blotch of copper to act as future site of any of the sporadic bursts of plasma that the comet now undergoes periodically."

Wrong again, sort of. What actually happened went completely beyond all expectation.

I wrote:

"It is also possible that no significant fireworks display will be seen. *Comet Tempel 1* comes to perihelion outside of the orbit of Earth, and originates from the space beyond Jupiter. Its charge is likely to be mostly equalized to the local electrical field of the Sun, as can be seen from the small jets of plasma which are only sporadically emitted."

"But I can certainly predict expected mainstream reactions."

... and listed the following:

- "In the event of a small impact crater, NASA will come up with a new theory of super-hard ices in space, or suggest a 10-foot-deep impenetrable crust of solidified rock."
- "If the copper-coated impact area becomes the favored location of new flares, it will prove to NASA that the comet is 'outgassing' at a new location, and probably due to an assumed deep hole made into the ice."
- "A flare-up of the comet before impact will suggest a slight mishap, to be cast in terms of, '*An unexpected disruption of subsurface ice exploded in the direction of the probe, due to gravitational shock waves, gravitational eddy currents, gravitational inequalities, gravitational tidal forces.*' [joke]"

Added note: This was a joke, but two months later NASA is suggesting that perhaps the other marks on the comet, which are normally assigned to impacts, might be due to underground "icy volcanic eruptions."

I wrote:

"We will again be left with nothing proven. Stay tuned."

That turned out to be correct.

Wallace Thornhill

On July 3rd, 2005, a day before the impact, the Saturnian Group also made some public predictions for the impact of the 800-pound projectile fired at *Comet Tempel 1*. See the TPOD by Wallace Thornhill at [\[thunderbolts.info\]](http://thunderbolts.info).

Specifics were listed as follows (abbreviated by me, with some comments added in square brackets):

- "*The most obvious [result] would be a flash (lightning-like discharge) shortly before impact.*" I should point out that this prediction was the most radical and interesting, and the one which rushed the press to Australia. But they dispersed as soon as they learned that

Thornhill would base his prediction on the theories of Velikovsky. A later web-based blog called the Thunderbolts.info "a crank web site set up primarily to sell crank books." More obvious comments on this further below.

- *"The impactor may form a sheath around it as it enters the coma, becoming a 'comet within a comet.'" [that would not be at all obvious, except that a 'space charge' might disrupt radio communication.]*
- *"Electrical stress may short out the electronics on board the impactor before impact."* [This of course would be true only if an initial electrical contact from the comet was to be of astounding magnitude. The space charge surrounding the projectile would in effect isolate it from the electrical properties of the comet.]
- *"More energy will be released than expected because of the electrical contributions of the comet."*
- *"Copious X-rays will accompany discharges to the projectile, exceeding any reasonable model for X-ray production through the mechanics of impact."*
- *"Any arcs generated will be hotter than can be explained by mechanical impact. If temperature measurements are made with sufficient resolution, they will be much higher than expected from impact heating."*
- *"The discharge and/or impact may initiate a new jet on the nucleus (which will be collimated -- filamentary -- not sprayed out) and could even abruptly change the positions and intensities of other jets due to the sudden change in charge distribution on the comet nucleus."*
- *"The impact/electrical discharge will not reveal 'primordial dirty ice,' but the same composition as the surface." [rock!]*
- *"The impact/electrical discharge will be into rock, not loosely consolidated ice and dust. [this restates the above] The impact crater will be smaller than expected."*

Tom Van Flandern

Long after the date of the impact I became aware of Tom Van Flandern's predictions, written in January of 2005, seven months before the impact date:

"The comet nucleus is a single, solid asteroid. The impact will leave a small, shallow crater perhaps 10-20 meters in diameter, will produce no new jet, and will have no lasting consequences on the comet. It will simply produce an impact flash as the probe vaporizes, then will cause the comet's coma to temporarily brighten as new carbonaceous dust is ejected from the asteroid regolith and the impact crater."-- Tom Van Flandern, <http://metaresearch.org>

Van Flandern's predictions were **absolutely correct** -- based on his conviction that comets are rocks. Van Flandern does not allow for electrical interactions, which ended up widening the "impact crater" and heaved into space an incredible amount of fine dust.

But it seems almost immaterial to be so dead-on correct, as Thornhill was, for there is a much

larger issue -- the investment in the current model of comets as soft conglomerations of particulate matter. As Van Flandern writes, "The dirty snowball model is not sure what will happen, but has an explanation ready for each possibility. In that way, the model will not be placed at risk of falsification." He continues:

"In brief, there is a general expectation that the impact will be gravity-dominated, while respecting the possibility that it might be strength-dominated. Either result will be argued as supporting the dirty snowball model for comets, even though the latter implies that the comet has been heavily processed and is not primordial."

"Just as Kuhn predicts for the nature of paradigm shifts, [T.S. Kuhn, 'The Structure of Scientific Revolutions' (1996)] one model will not overthrow the other on merit, but the incumbent model will be patched until it so closely resembles the competitor that no important distinction remains. That helps to maintain the illusion that the progress of science is always forward."

The Fireworks

[July 5, 2005:] The first observations of July 4th, from a number of sources, compared with predictions as listed above.

"... at best only a small crater would be made."

Although difficult to measure, a NASA spokesperson suggested "at least bigger than a house," that is, 30 feet (10 meters) in diameter -- not 250 feet. This changed soon, for as soon as the impact crater was made, electrical arcing started up at the edges. Over the next few days this would enlarge the original crater to form a shallow depression as the electrical arcing wore away material from the sharp edge. Thus the original suggestion of a crater the size of a house was soon modified to suggest that it was much larger.

"an explosive arc at the impact location well before the probe arrives ... followed by a sudden arc from the comet to the probe"

The initial flash at the impact point was bright and small -- and of only 50 milliseconds duration -- and separate from a secondary conical blast of material. I have no idea of the timing of this bright spot, that is, when it first appeared. The probe was to take images every 2 seconds until impact, but the last image was transmitted 3.7 seconds before (calculated) impact. I would suggest it was "hit" at this time. The probe was traveling a little over 6 miles per second, with 24 miles to go before impact. The probe also faltered twice in earlier transmissions during approach. It would suggest electrical disturbances, that is, plasma sheath shielding (mentioned as likely by Thornhill).

"... ending in a brilliant green flash as 800 pounds of copper are vaporized."

That was my suggestion and I was dead wrong about that. I admit that I never took note of the approach speed -- which was on the same order of magnitude as for a meteorite strike to Earth. I was actually surprised that this speed was attempted, because for objects in space the speed of impact is determined by the escape velocity of the larger object. For Earth this is 25,000 miles per hour. For the Moon this is 5,000 miles per hour. For smaller objects it is much less. For an asteroid sized comet this would be only a little more than nothing.

Also, I have seen nothing more anywhere of all the copper molecules which should have been part of the initial impact explosion.

"... [the copper molecules] will provide a future site of any of the sporadic bursts of plasma that the comet now undergoes periodically."

After the initial flash, material was noted as being ejected straight up in a column. That is certainly not the mark of impact ejecta; it is the mark of a cathode strike. This was correctly predicted by Thornhill. NASA would suggest later that this meant that the probe bored a deep hole in the snow and ice, like a well or a gun barrel, which "shaped" the initial ejecta.

A conical ejecta started after the initial appearance of the column, and became increasingly larger with time. Although this could be understood as a large and deep hole made in the surface, it could also be a shallow crater whose size is progressively being enlarged by electrical sputtering at the edges of the crater. The conical ejection seemed to be sidelit by the Sun. We will have to see if this stops or continues.

"More energy will be released than expected because of the electrical contributions of the comet."

"Copious X-rays will accompany discharges to the projectile, exceeding any reasonable model for X-ray production through the mechanics of impact."

Thornhill was certainly correct in this. Van Flandern did not anticipate this, because there was no electrical interaction presumed. The sustained burst after impact amazed all the researchers. They have had to go to extremes to explain it.

No mention has been made yet of spectral analysis. As with Halley's Comet in the 80's, an X-ray source will be identified, and then simply neglected.

"In the event of a small impact crater, NASA will come up with a new theory of super-hard ices in space, or suggest a 10 foot deep impenetrable crust of solidified rock."

NASA has in fact suggested the opposite, namely that the probe hit a soft outer layer before being crushed (in actuality "vaporized") by deeper harder material ("ice"). The suggestion follows from the massive conical "flare" which appeared and enlarged after impact.

"Because the impact area is in sunlight and thus facing the Solar Wind of incoming protons, more water molecules will be produced by combination of protons with the oxygen ions than what is normally found in the outer reaches of the tails of comets."

Did I say this? This clearly has turned out to be untrue -- much fewer water molecules were being produced than expected.

"The discharge and/or impact may initiate a new jet on the nucleus and ... could even abruptly change the positions and intensities of other jets."

It was initially claimed that the relocation of jets did not happen. It was later claimed that the relocation of jets did happen. Actually, no one took note of any of this, for it was certainly not a concern of the accepted model of a comet. But the intensity remained the same. Two weeks later the comet had returned to the sporadic bursts of plasma which it exhibited before the impact.

The Aftershocks -- A Week Later

NASA kept talking of snow and ice in their press releases. Other sites investigating the impact had other things to say, at times in contradiction.

The first images returned from the Deep Impact flyby spacecraft showed a small fireball followed by a much larger, incandescent flash that engulfed one end of the comet Tempel 1. Observatories on the ground reported that the explosion brightened the comet by a factor of five within 15 minutes of impact.

It is really strange how the flash expanded quite slowly -- as if the edges of the crater were on fire. But this is entirely expected as an electrical phenomenon.

The impact sent up twin plumes of debris, the first appearing as a narrow column that cast a long shadow across the comet. Another plume appeared seconds later on the heels of a brighter explosion, then fanned out in a star shape.

Co-investigator Pete Schultz said the twin flashes showed that the impactor encountered softer, layered material on the comet's surface then hit a thick, hard crust. (Sydney Morning Herald, July 6)

A comet is composed of two parts, the larger coma, seen in glow-level plasma discharge, and the rocky interior, called the nucleus, which is the source of the coma. The initial plume was probably the ionization of the trajectory of the impactor, made visible with a glow-discharge plasma expulsion. It was not impact debris, which would create a spherical expulsion of material.

Scientists studying the Deep Impact collision using NASA's Swift satellite report that

comet Tempel 1 is getting brighter and brighter in X-ray light with each passing day.

The X-rays provide a direct measurement of how much material was kicked up in the impact. This is because the X-rays are created by the newly liberated material lifted into the comet's thin atmosphere and illuminated by the high-energy Solar Wind from the Sun. The more material liberated, the more X-rays are produced. (from harvard.edu/press/pr0523.html)

That was just **totally bogus**. X-rays are produced by intense concentrated electrical arcing, and not by interaction of the ionized material with the incoming Solar Wind, which only interacts at the limits of the coma, not by dust locally lifted into space.

[Added Note: It has been pointed out to me by others too that the Solar Wind probably has nothing to do with this. If silicates were released by arcing, and electrostatically repelled from the arc site, the surplus of electrons available from the comet, at the same location, would be enough to account for the production of X-rays.]

[Note: I have deleted most of the remaining comments I initially collected from the scientific community. These just go around in circles, never settle on anything definitive, and frequently contradict each other.]

Summing Up

- One source, looking at the ultraviolet flash, says the impactor hit a hard surface. NASA and related sources assume a soft surface on the basis of the dust cloud.
- One source discounts any increase in water vapor after the impact. NASA still holds that ice was hit.
- NASA and others are surprised at the fine powder lifted into space by the impact. They had expected coarse-sized debris as would happen if the cloud were ejecta from an impact.
- Many sources were completely surprised at the size of the flash, assuming this to be volatilized material -- supposedly water vapor, and the fact that it continues unabated a week later.
- One source has identified the "ejecta" as composed of silicates -- ground up rock. NASA has been mum on this.
- Any number of sources assume that the X-ray production is caused by the Solar Wind impinging on the "dust." It is an interaction with ions and electrons.
- The preliminary flash and the subsequent plume which rose straight up remain unidentified.
- The size of the crater remains small despite the fact that enormous amounts of material are being lifted into space (into the coma).

Two Weeks Later

The only news is that NASA now claims that the comet was covered with "cosmic talc" which would account for the gigantic -- and totally unexpected -- clouds of "dust" after the impact, which subsided after a few days or a week. NASA still does not know the size of the crater, guessing at 150 to 750 feet (250 meters). Apparently the crater size has increased, as expected, from the initial guess of 30 feet (10 meters).

The relocation of the periodic bursts to the impact site has not happened. The ESO reports: The flare only lasted a few days, and two weeks later the comet had returned to its earlier intermittent flares, at old locations. The ESO also claims that the impact "has failed to free up a large quantity of untouched material from beneath the surface."

Meanwhile, Thornhill has posted a summary of findings at [\[www.holoscience.com/news.php?article=3kneumjj\]](http://www.holoscience.com/news.php?article=3kneumjj) and [\[www.thunderbolts.info/tpod/2005/arch05/050719deepinterim.htm\]](http://www.thunderbolts.info/tpod/2005/arch05/050719deepinterim.htm).

Thornhill also suggested (in a previous post) that NASA is rapidly forgetting things -- like the initial flash, and the magnitude of the blast of light. This last is being turned into "sunlight reflecting on fine dust" rather than the more obvious "electrons in a state of high excitation." Of course the fine dust will be there as the initial cathode strike sputters solid rock into tiny fragments -- but so will the electrons and ions. Thornhill also mentioned that data is being removed from NASA websites.

Two Months Later

(November 2012) I have removed all the original quoted source material, because there was such a surplus. But I have retained the comments these generated.

"Keeping it anchored" (originally in the removed quoted) is a typical iffy phrase. To the researchers the cloud is a glob of dust anchored to the comet. They cannot imagine how it is held in place after being ejected. The forward speed of the dust should have released it entirely from the gravitational grip of the meteor.

The plasma people understand it differently. The particulate matter is ionized silicates -- electrically charged rock dust. The particles are electrically repelled from each other, and therefore spread away from each other. That accounts also for their initial leap off the surface. But at the same time they are attracted to the negatively charged surface of the meteor and continue to hover.

The "strange behavior" of a very weak gravity, the "gluing together" of microscopic dust particles, the assumed "baking" by the Sun, the older impact sites which show only slight indentations to the "soufflé" surface, the "shock wave" which took five minutes to travel 50 yards, a plume of dust "anchored" by gravity, the suggestion of "icy volcanic eruptions," the deep penetration hole [presumed to be 90 feet deep] which has yet to be seen, and the

repeated equipment failures -- these all speak of soufflé science.

It is interesting that diverse readings -- the plasma version and the dirty snowball version -- could be extracted from the same data. Yet all the data is there. The snowball version, however, lacks any substantial physics; the concepts are constantly undercut with inexplicable "surprises."

I have a fair suspicion that NASA knows damn well that the projectile hit a giant rock, not a pudding of mushy snow, that the fireworks were an electrical explosion, and that the cloud of "dust" was rock which had been vaporized in the electrical explosion.

But this information should not enter the public domain, because it will cause unneeded anxieties. If people knew that comets indeed consist of solid rock, and additionally are capable of exploding electrically, there would be panic about what would happen if a comet ever approached Earth. The earlier idea of, "we'll just nuke it," would have to be removed from consideration if comets are solid rock and if we get the sort of energetic reaction that we have just seen with the impact of a mere 800-pound chunk of copper.

Retaining the idea that comets are just cotton candy keeps them nukable, makes everyone feel confident that we can control these objects, and extends research funding for NASA.

Six Months Later

In January 2006 a package from the spacecraft "Stardust" landed on Earth. I'll quote the leading paragraph from thunderbolts.info's TPOD:

"The first results from NASA's Stardust mission are in, leaving mission scientists in a state of shock and awe. The tiny fragments of comet dust brought back to Earth [anorthite, forsterite, and other silicates] did not accrete in the cold of space, but were formed under 'astonishingly' high temperatures."

-- [\[www.thunderbolts.info/tpod/2006/arch06/060316stardust.htm\]](http://www.thunderbolts.info/tpod/2006/arch06/060316stardust.htm)

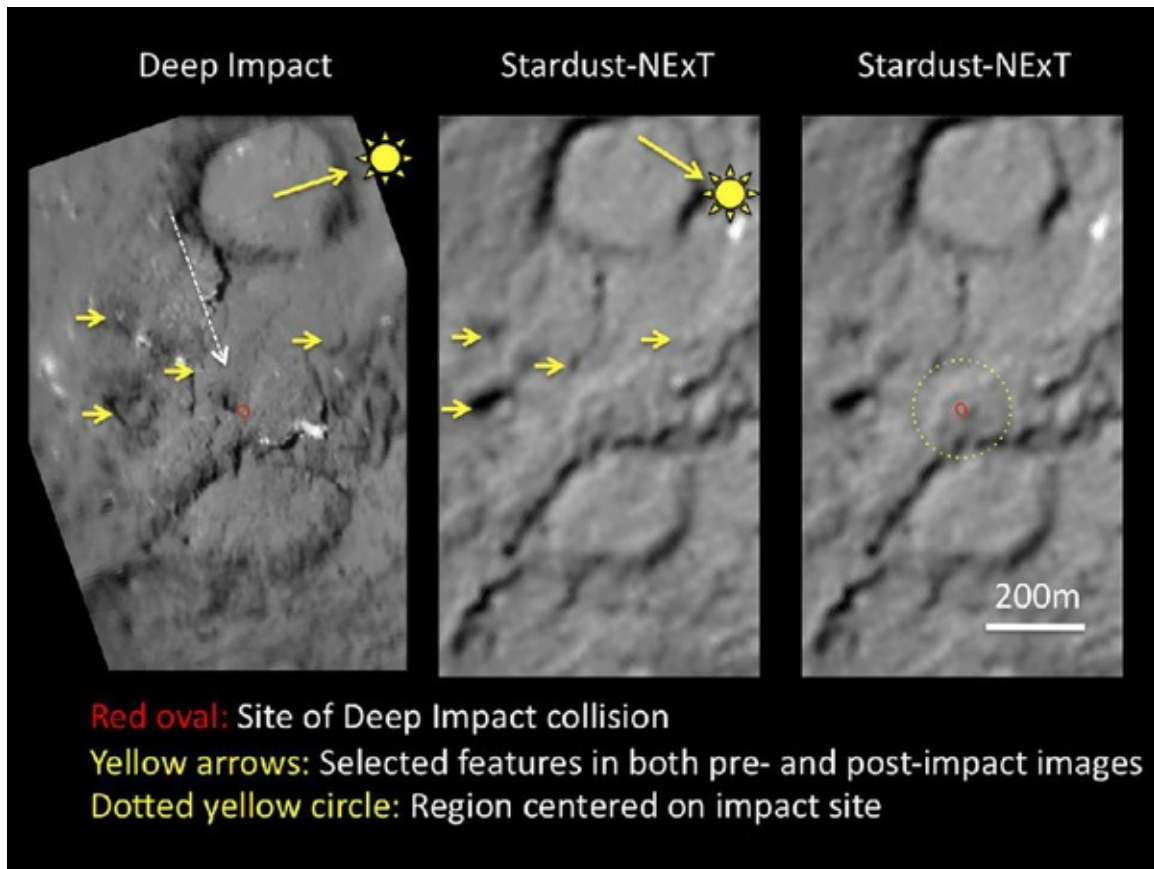

The stuff consisted of silicates -- rock dust.

Two Years Later

Official papers were published in *Science* in 2005.

In the book *The Electric Universe* (2007), Wallace Thornhill and David Talbott elegantly sum up the evidence of the two positions I mentioned above -- that comets are rocks, and that the interactions will be electrical -- for Comet Tempel I and for 15 years of space research (along with other *Electric Universe* aspects).

Six Years Later

[Image: Deep Impact contact area with comet Tempel 1, 6 years later, February 2011. After NASA.]

In February of 2011, NASA has rerouted a spacecraft to take another look at Tempel 1, now six years since the impact by Deep Impact. The inspection tour was known as the Stardust-Next mission. The area of the 2005 impact was photographed, and did not show what was originally thought to be a 90-foot deep hole the size of a football field.

It is hard to tell, for although NASA claims that there is a depression of 150 to 250 feet (50 to 85 meters) , there is no shadow and no show of any depth. Representing NASA, Peter Schultz claimed "We see a crater with a small mound in the center..." I see no crater at all. But then Schultz goes on to explain this as "some of the ejecta went up and came right back down."

And then comes the soufflé conclusion reached by Schultz, "This tells us this cometary nucleus is fragile and weak based on how subdued the crater is we see today," but in complete contradiction to all previous theories offered by NASA. Ratcliffe wrote at one time: "theories from the secret minds of tadpoles."

"The ingenuity of such nonsense is breathtaking."
-- Wal Thornhill, 2004

Speculative Cosmologies

Following are some alternative cosmologies which do not explain or do not hold together, even though many are well researched. I have added my comments only as needed. Most are not so much complete cosmologies as they are explications of catastrophic events in the era from 10,000 BC to the 7th century BC. Most take for granted the current state of the Solar System and the handed-down narratives of its genesis. That will do, although, as described on these pages, it is seldom correct.

[An added note, May 2015] I have had to drop a number of these for they completely disappeared off the internet. Others which were originally listed in this Appendix are covered among the endnotes of Chapter 2. I have kept some classic catastrophists.

Even a complete mythological fantasy would retain the physics of the universe. That is the basis for fantasy: it has to play out within the realm of the possible, and thus the basics of physics are retained.

Or not. The basics of physics are all too frequently misunderstood or just rewritten. If it seems right, it is assumed to be right. The audience for alternative catastrophic cosmologies often consists of people who cannot tell physics from commonly held misconceptions, and, in fact, seem to misunderstand basic geometry.

But don't let details get in the way. As remarked by Kurt Gödel, "Concepts indifferent to the details of their formulation are absolute." There are broad concepts among the various catastrophic cosmologies which are inured to the details of different retellings, which fare much better on a scale of "intuitive speculation" (as Tom Van Flandern calls it) than String

Theory or Dark Matter. One of these cosmologies, or some of these, or various parts of some of these, are absolute and will represent the true history of the past.

And who would want to rewrite physics and astronomy? I think the real question is, Why are we afraid to enter the imagination of the ancients? Certainly we should be able to make sense of what lies behind "How the ancients perceived the universe." Could we not exercise *our* imagination to find possibilities without rewriting physics?

The following is a sampling of the work of others who believe this to be true, ranging from bizarre to sublime. I started to understand "fringe" as a border of loose threads, rather than "outer edge," although I respect the work that went into these. Some are followed by comments. Others require none.

If I have misrepresented anyone, it is an oversight. I will gladly correct the capsule descriptions below, although my evaluations will (probably) remain the same. I have excluded the works by Immanuel Velikovsky, David Talbott, Wallace Thornhill, Tom Van Flandern, and a number of others. See the Books Appendix and Links Appendix for more.

== Zecharia Sitchin ==

From an article in *Atlantis Rising Magazine* describing the work of Zecharia Sitchin, *The 12th Planet* (1976) and additional books, *The Stairway to Heaven* (1980), *The Wars of Gods and Men* (1985), *The Lost Realms* (1990), *When Time Began* (1993). The official website is at [\[www.sitchin.com\]](http://www.sitchin.com) but less lucid.

"... According to Sitchin, mankind owes most of its ancient legacy to visiting extraterrestrials. The Russian-born Israeli resident and ancient language expert has indeed come up with some very intriguing, if not compelling, data. Indeed, few can match Sitchin's scholarly credentials. One of a handful of linguists who can read Sumerian cuneiform text, he is also a recognized authority in ancient Hebrew as well as Egyptian hieroglyphics."

A single mention of "extraterrestrials" is enough to turn me away entirely. Such insanity can only be sustained by someone who has not the slightest concept of the dimensions of space and who lacks an appreciation of the span of time it has taken for life to achieve the complexity we experience.

== Eric von Daniken ==

Eric von Däniken's book *Chariots of the Gods* (1968) is alive at the site where the "Archaeology, Astronautics & SETI Research Association" publishes the quarterly *Legendary Times* on the web. To quote from their opening page:

"The A.A.S.R.A. is determined to prove whether or not Extraterrestrials visited Earth in the remote past. In his ground breaking book Chariots of the Gods, Erich von Däniken brought forth a revolutionary theory: Extraterrestrials visited Earth thousands of years ago."

"They left clues behind in the form of mysterious, enigmatic monuments, curious artifacts, misunderstood technologies, and especially stunning descriptions of flying machines and other curiosities in ancient texts, holy scriptures and tales of mythology. What really happened in the past?"

What really did happen in the past? Conceive of humans as being as clever and industrious as we are today, and no extraterrestrials are needed. [\[www.legendarytimes.com\]](http://www.legendarytimes.com)

I do not buy any of this, and fail to see the "message behind those mysteries." The "mysteries" are all the same stuff anyway. Writers: Erich von Däniken, David Childress, Peter Fiebag, Robert Bauval, Ulrich Dopatka, Luc Bargin, Giorgio Tsoukalos.

--= Mars-Earth Wars =--

Donald W. Patten and Samuel R. Windsor *The Mars-Earth Wars* (1996). The authors are physical scientist and engineers, making their theories a little more solid. The authors are sincerely enamored of the "dirty snowball" theory of comets, however:

"This new model of cosmology accepts the evidence of planetary catastrophes surrounding us. It is a model of recent orbit changes among Venus, the Earth and Mars. While not an 'original thought,' the claim is that a reorganization occurred within the cultural memory of numerous groups of the Earth's inhabitants, who recorded their experiences."

-- [\[www.creationism.org/patten/PattenMarsEarthWars/index.htm\]](http://www.creationism.org/patten/PattenMarsEarthWars/index.htm)

Don't let the domain name scare you, this is a reasonably well-written piece about the intersection of the orbit of Earth and Mars through the 8th century BC. But the backtracking through well-mannered calculations does not constitute a confirmation. It offers a single and what I think is a rather simple solution, much too rigid and invariant in its mechanics, of the near-contacts with Mars during this time period, extending back to Mars being hit by some (watery) asteroid. It fails to give an account of any previous celestial history, or suggest a closure.

Although momentum and energy equations are carried out to many decimal places, the difference in orbital inclination to the equator of the Sun is not taken into account. Patten and Windsor hold that the orbits of Earth and Mars were coplanar (which is more or less correct).

I disagree also with their selection of 701 BC as the date for the terminal event of Mars,

which enlarged the Earth's orbit. There is just too much evidence that this happened in 747 BC, from calendar considerations -- such as the start of the Era of Nabonassar and the start of the Olmec Long Count.

A major objection is that Patten and Windsor have Mars pass between Earth and the Moon in order to increase the orbit of Earth and reduce the orbit of the Moon -- both by gravitational attraction. It also forces them to have Mars pass significantly closer to Earth; the evidence of Hesiod's *The Shield of Hercules* is used in partial support of this. The possibility of a "shove" instead of a "tug" is not considered, probably because much of the plasma theory as applied to planets was still undeveloped at the time of their initial authorship. Mars could have "shoved" the Earth with an electric field repulsive force from a much greater distance. Even though Mars would not have had a large plasmasphere, it still would have had a tail, an electrical shadow, on the side away from the Sun. The intersection of this with the plasmasphere of the Earth would have sufficed to provide the shock.

Despite my reservations, I found *The Mars-Earth Wars* to be interesting and I have used it as a resource in my own analysis. Patten and Windsor agree that there was no precession of the equinox before 701 BC, but for different reasons from mine (I use before 747 BC), and also failed to recognize the 15-day offset in the calendar in 685 BC. We agree on periodic flybys of Mars, but use a different interval from my selection (I follow the suggestion by Velikovsky, which can be verified from Mesoamerican sources). Lastly, I adopted Patten and Windsor's value for the synodic period of Mars, and managed to verify it through rather arcane Mesoamerican calendrical measures, the 819-day calendar rotation.

-=-= Ackerman's Firmament =-=-

John Ackerman ("Angiras") in *Firmament: Recent Catastrophic History of the Earth* (1996), *Chaos: A New Solar System Paradigm* (2000), and *Peleh: Hidden Knowledge* (2006) establishes the repeated meetings of Earth and Mars (and Venus) primarily from Vedic sources. Ackerman is a physicist who talks plasma without a single concepts of what it is.

"Prior to 4000 B.C. there existed only two terrestrial planets, what I call priori-Mars and the Earth. That is, Mercury and proto-Venus were not present in the solar system. Priori-Mars, the more ancient of the two by some 800 million years, was in an orbit similar to that of Venus today. It had a thick atmosphere, lots of surface water, rain, and a myriad of life-forms similar to those found on Earth. The entire planet was covered with vegetation."

My estimate of the age of Mars and Earth is exactly the reverse, as I have pointed out in the appendix "Notes on Chronology." If Mars had been subjected to repeated electrical arcing from Saturn impinging on its northern hemisphere, all life-forms (if there were any) might have been burned to a crisp and obliterated. But that's just *my* opinion.

"One of the most profound ideas suggested by the Velikovsky/Ackerman (V/A) scenario is an understanding of how a higher power may have only recently regenerated the Earth to enable its population by billions of human beings. ... The V/A scenario makes it possible for us to understand how major changes in a solar system were activated by small physical actions leveraged by a level of intelligence far beyond our own."

The tip-offs are "a higher power" and the "level of intelligence far beyond our own." I do not see the need for any of this. Ackerman eventually proposes that Earth is populated by Martian life. His third book reveals him as a dyed-in-the-wool uniformitarian and Christian fundamentalist with Rapture leanings. He also largely follows Sitchin, combining it with ideas from Velikovsky.

Ackerman has Mars stand still over the Himalayas for 15 years at a time, thus raising the mountains to great heights. The iron core of Mars leaks out of the Valles Marineris, which is thought to be a giant crack in the surface of Mars. The iron core bundles up, and starts revolving about the Sun independently, eventually to enter Mars again at the end of the 15-year period. At the very last instance of this repeating cycle it fails to return, and now circles the Sun as the planet Mercury -- magnetic, dense, and smaller than Mars. This supposed scenario requires a magnetic field for Mars. Another feature is long tubes of lava which extend from Mars towards Earth. During these many visits all the Martian oceans and vegetation leak out and are cast onto Earth.

What is amazing is that the detailed information, presented over three books, forms a close fit

to what I think is a completely unjustified cosmology. It should be a warning for any other neo-catastrophist who attempts to put all of mythology together into a singular cohesive system: It can be done, but means no more than filling in a crossword puzzle with random words.

== Clube and Napier's Snake ==

The Cosmic Serpent (1982) by Victor Clube and Bill Napier is a slipshod and unconvincing book which attempts to suggest a basis for ancient catastrophes in supposed meteors (or comet) strikes. Clube and Napier are astronomers, but show an incredible ineptitude when it comes to antiquity, mythology, and perhaps especially when it comes to astronomy. *The Cosmic Serpent* deserves extensive comments, because it is held in high regard by many people, perhaps because it "looks so scientific." I will start with a short description by Bob Kobres, from his website (which promotes the cause of explaining all of the past in terms of meteor impacts)..

"Clube and Napier suggest that Jupiter and Saturn occasionally divert giant comets into the inner solar system into short-period orbits. Debris from the resultant disintegration of these giant comets can adversely affect the environment of the Earth. Dusting can block sunlight, resulting in globally cooler conditions."

-- <http://abob.libs.uga.edu/bobk/>

As has been pointed out by others, we have traveled through the tails of comets in modern times, with no harm or notice of the effect. On the other hand, a few lobbed atomic bombs would probably reduce sunlight for decades -- due to persistent nanometer-sized dust in the stratosphere. But raging wildfires would have the same results. There has been both "mythological" as well as climatological (archaeological) evidence for extensive fires in the remote past. Kobres goes on:

"Impact events in the Super-Tunguska class may result in not only heavy localized destruction but also the occasional 'impact winter' or dust veil with global climatological effects. Clube and Napier identify the progenitor of the Taurid complex as such a giant comet whose injection into a short-period (about 3.3 year) orbit occurred sometime in the last twenty thousand years."

"The effects of the disintegration of this object in an Earth-crossing orbit should appear in the geological and climatological record as well as in protohistorical and historical records."

"Clube and Napier ... also seek evidence of catastrophic events in ancient mythology. Their contention is that the great Taurid progenitor was the basis for much of the mythology associated with 'sky gods' and themes of generational conflict along gods."

It seems rather highly amazing if ephemeral phenomena like meteors or even repeating meteor showers formed the cast of the theater of "sky gods" of antiquity, most of which have unique identities and many of which persisted for 3000 years. To go on with Korbes..

"Clube and Napier note that many of the themes Velikovsky ascribed to 'comet Venus' rightfully belong to the Taurid progenitor, and at least some of those ascribed to Mars by Velikovsky rightfully belong to Halley's Comet."

-- Bob Kobres

The authors Clube and Napier, in fact, completely dismiss Velikovsky's work as "wildly improbable" and "absurd speculations," except when a single observation by Velikovsky fits their thesis.

Alfred De Grazia wrote, in *Cosmic Heretics* (1984),..

"Like many others working on catastrophism, the two Edinburgh astronomers find themselves isolated, both because of the extremity of their ideas and because they need much material from fields like mythology and linguistics that they cannot grasp themselves nor command expert consultants to provide for them."

They do not need "expert consultants." Anyone with a brain and some study time can acquaint themselves of the facts. But I think "cannot grasp" is a well placed critique. It is probably precisely because of the overall ineptitude and cluelessness that this book has stood as a monument to overactive imagination. Nothing much can precisely be negated because nothing much is asserted with anything backing it up except a sort of spongy foundation.

The persistence of this counter-myth is amazing. However, the specificity of the infrequent electrical contacts with Venus and the coincidence of dates in the eastern Mediterranean region with records in Mesoamerica cannot be explained by Taurids or Halley.

Meteors do not cause Earth shocks, or send the Earth to a new orbit, or turn the sky blood red for days, shoot arrows upward into the sky, suddenly show up the Pleiades, send tsunamis across the Pacific, boil up oceans of water, scar the land with traveling arcs, dump yards of incinerated trees and soil on hilltops, or cause a thousand years of constant earthquakes. In fact, they cause **none** of these.

I do not doubt that meteor swarms have been recorded since 34,000 years ago (as I have pointed out). But I seriously doubt if meteors have ever had any significant impact on mythology, or, for that matter, even on the weather.

The book of Clube and Napier is held in high repute (by some, and rather unqualified at that) because of the qualifications of the authors (they are, after all, Edinburgh astronomers), but moreso because the subject matter is totally inarguable. Comets are ephemeral, and just about anything can be said of them, especially in the past tense. The Yucatan Chicxulub "impact

crater" has lent its reputation to the tales of comets.

Walt Thornhill at his website, [\[holoscience.com\]](http://holoscience.com), makes note of the ease with which writers of catastrophism tracts, and even, as we see here, professional astronomers, imagine a "fanciful" past that never happened. He writes..

"...[there is a] crucial distinction between the planetary catastrophism of the Electric Universe and that of neo-catastrophists who attempt to explain the evidence for planetary encounters in terms of cometary phenomena. Modern comets simply do not fit the descriptions from the past. Nor can they account for abundant evidence of fresh looking planetary cratering and scarring. Besides, in an Electric Universe comets are not the apocalyptic threat to the Earth imaginatively portrayed by artists. Such pictures are entirely fanciful because a comet would be disrupted electrically by a cosmic thunderbolt before it hit the Earth. The only visible evidence remaining would be an electric arc crater."

Note that Kobres touts the contents of the book as "evidence," but evidence it is not. All of it, end to end, is speculation dressed up with tables and graphs; the primary subject is one of pure avoidance. The books represent the absolute cluelessness of mainstream astronomy: Comets are snow balls; stars and galaxies are generated from clouds of dust; dust in turn result from exploding stars; sothic dating is held as real; the invariant length of the year is fact; the dark ages of Greece are affirmed. A new chronology for antiquity is introduced, based on selecting a few elements from a single "study" while the remainder is rejected. Then every notion in mythic antiquity, questionable dates, and unrevealing graphics is paraded out to account for the complete pantheon of Egypt, Babylon, and Greece as comets, plus Typhon and Phaethon, and, of course, the celestial snake Apep.

... comets are snow balls

[p 23] *"We must seek to avoid total commitment to a particular scenario."*

You would expect this cautionary note near the beginning of the book to set the tone for all that follows. But it does not. It is only said with respect to the generation and description of galaxies, where the authors know for certain they are not treading on solid ground. But galactic matters, however speculative, have to be set in place, because, just as galaxies are made of dust, so are stars and planets, and so too must be the comets, so they claim.

From this point the book proceeds entirely by suggestions and innuendoes. Often the diverse current views (but none too radical) are given on an astronomical topic, yet when an opinion ("study") of a single individual is found which confirms some implications of the book, it is offered as fact. It is absolutely amazing how the authors segue from one topic to the next, as if a syllogism were being constructed, whereas only a loose collection of contiguous statements is used to insinuate a set of causal connections in a theory of cometary

catastrophism.

[p 35] *"Comets are conglomerates of ice and dust, perhaps with large boulders."*

The source of the comets is here placed in the spiral arms of galaxies, composed of planetesimals, a word (I presume) for "rocks." Then an opinion is offered on the makeup of comets, based on the initial suggestions from Whipple, the originator of the "dirty snowball" theory of comets in 1950 and 1951:

[p 43ff] *"Evidence has accumulated, however, in favour of the dirty snowball model developed by the American astronomer Whipple, in which the nucleus is seen as a lightly packed ball of ices including ammonia, methane, carbon dioxide but about 50 percent water ice. Imbedded in the ice are solid particles about 0.01 percent of a millimeter in diameter, that is, about the size of interstellar grains."*

No evidence has been accumulated at all. All of the above information is sheer conjecture. The nucleus of comets, in fact, look and act like solid rocks. "Interstellar grains" have never been seen or measured.

... stars are generated from clouds of dust

[p 35] *"The traditional view has been that stars are made by the collapse of huge, relatively hot masses of gas under their own weight. ... individual regions of the cloud are able to collapse separately, until they themselves fragment and so on, down to the point where the gas is so dense and opaque that further contraction initiates nuclear fusion, and stars are born."*

Laplace is mentioned in passing, and his nebular hypothesis, a notion which has never been affirmed and has frequently been disproven.

[p 58] *"... solar nebula, a disk-shaped region the extent of the planetary system, from which not only the comets but also the asteroids, planets and Sun condensed"*

... dust in turn result from exploding stars

[p 47] *"Inevitably, then, with this picture, the interstellar medium is steadily enriched by heavy elements produced in supernova explosions."*

The knowledge of supernovas has, of course, changed radically over the last decades. Although not yet admitted by astrophysicists, these are electrical in nature, or we would otherwise not be seeing repeating novas of the same star. Heavy elements are spat out continuously by the Solar Wind. This is sufficient to account for all except a few of the radioactive elements.

... and now for the comets

The authors also offer an unsupported opinion on asteroids..

[p 65] *"There are strong grounds for considering that most of these [asteroids] are degassed comets."*

Things have changed since 1983, and especially in the last 5 years. Comets are rocks, asteroids are rocks, and the interactions we see are electrical. The hydroxyl (OH) molecules detected in the tails of comets are not from sublimed water, but from solar wind protons (H⁺) and cometary Oxygen (O⁻) ions released from silicates. The silicate (rock) source has not been recognized yet by NASA, but the fact that the "water" in the cometary tails is due to other sources than subliming ice, has been noted. NASA still produces a lot of "ice" talk, perhaps because the press releases of NASA and other organizations are still written by PR crews who received their education 30 or 40 years ago.

[p 67] *"The essential point is that the asteroid system ought to look like the rings of Saturn rather than a doughnut. It [the asteroid belt] has too much internal energy, and ad hoc mechanisms have to be added to the conventional picture to puff the system up. One such proposed mechanism is the gravitational stirring of asteroids by massive planetesimals which were once scattered into the belt, but have since vanished."*
[numerical examples are given]

This is a typical case of Clube and Napier connecting disparate dots in the data to graph their way through a series of statements and reach a "conclusion" favorable to their thesis. Amazingly, here we see the suggestion of bad ad-hoc emendations (admitted by the authors) to faulty theories (also admitted by the authors), but then the authors accept these as fact. Anyone in their right mind would suggest that the bad theories which have to be patched ought to be dropped.

... meteors are launched into the inner planetary space

[p 88] [about meteorite dates] *"Most of the ages cluster around 4.5 billion years"*

Where did they get this? The *Encyclopaedia Britannica*, 15th edition, which has the same publication date as this book, disagrees completely. The statement might be slightly correct in that some meteorites are quite old, but only the iron meteorites, which are a distinct minority of one percent, have been dated to 4.4 and 4.6 billion years. Most are quite recent in comparison -- to under 700 million years, with some under 100 million years. "Clustering" presumes an equal portion with ages greater than 4.5 billion year, suggesting that some are as old as the accepted age of the Universe. Most are 3.5 million (note: not billion) years old, with a spread to 40 million years. A far stretch to 4.5 billion.

[p 146] *"The significant feature [of comets] is not collision with comets themselves but with their debris. For comets spread dust and rocks along their orbits; and as we have seen already, they are often observed to split and sometimes disintegrate."*

As I have pointed out earlier, the idea of "collisions" leaves a lot to be desired, considering that comet and all the parts of comets are traveling at the same speed. Reducing the colliding objects to dust is just absurd.

... Sothic dating

But first, dates offered by 16th-century researchers are dismissed.

[p 220] *"Rockenback's sources are lost and the merging of Exodus and Typhon might still be apocryphal...."*

Rockenback is actually fairly specific in differentiating between his historic sources. Some of the church fathers came to the same conclusion: Typhon appeared at the time of Moses.

[p 227] *"So the Sothic calendar stands today virtually unchallenged, and with all the authority that its successful use for nearly eighty years can provide."*

Let me point out the Sothic dating is entirely bogus, and, although the notion is endlessly repeated in text books, it has today been abandoned. Peter James (among others) notes, at <http://www.centuries.co.uk>..

"The Sothic theory depends on a number of assumptions which do not stand up to close scrutiny. Since our first published criticisms (James et al. 1987, 71-74) there has been a sea-change in opinion as to the reliability of this astronomical dating."

"As there are no longer any reliable astronomical fixes, Egyptologists have, by and large, abandoned their reliance on Sothic dating -- although they have been rather slow in admitting it in public."

To continue with Clube and Napier..

[p 228] *"Thus, although archaeologists have come to depend totally on the validity of the [sothic] cycle, it remains to this day a very disturbing fact that there is no known reference to the Sothic cycle in Egyptian texts."*

No kidding! There are Egyptian sources, but these refer to Sothis (female ending) as Venus, rather than Sothis (male ending) as Sirius. Both mean "bright." Clube and Napier next proceed to revise the dating of antiquity to meet their particular needs.

... the set length of the year

Clube and Napier next [p 226] take selections from R. A. Parker, "The calendars of Ancient Egypt," in "Studies in Ancient Oriental Civilizations # 26" (1950), which suggests an intricate system for an Egyptian lunar calendar, based on the current length of the year, sothic dating, and a 30-day month (although I cannot follow this at all), to come up with a date of 1369 BC for the year of the Exodus (and thus for the appearance of Typhon). (Here they neglect to mention that they had dismissed Rockenback's "apocryphal" identification of Typhon with Exodus.)

This analysis includes repeated calendaric corrections instituted by various pharaohs (Parker). Clube and Napier accept some of Parkers analysis, and out of hand reject other portions. The Giza Pyramid construction phase is dated to 2196- 1687 BC, rather than 2590 to 2500 BC [p 236]. I could not believe I read this!

The revised chronology which has been devised by Clube and Napier is then justified in reference to the access shaft of the Great Pyramid at Giza, as follows..

[p 237] *"... the Descending Passage, which slopes steeply downward for over 100 metres into the Great Pyramid, was aligned precisely on the then Pole Star, Alpha Draconis [Thuban], about 2160 BC before it precessed away from this position. This and other arguments led Piazzi Smyth [in 1867] to favor 2170 BC [for the construction]. Such dates agree very closely with that of the Great Pyramid construction on the revised chronology [by the authors] but have no relevance to the date of 2600 BC implied by the standard chronology."*

I can't believe I am reading this: "aligned precisely." And this is written by astronomers! Forgive them for the absurd dates, but ask, Have they ever looked at the sky? Let me note that a retrocalculation based on the current measure of the precession of the polar axis, in the winter of 2170 BC, Thuban was not the pole star, but turned in a circle about the north celestial pole. As Thuban passed the north meridian (at 7 pm at the winter solstice) it dropped down to an elevation of 26.4 degrees above the horizon. It passed through the elevation of 26.4 degrees nightly for hundreds of years. This is not a "precise alignment" at all.

At no time was it ever at the required 30 degrees above the horizon. At the latitude of Giza, the center of the sky, the location of the polar axis, is at 30 degrees above the horizon, not 26.4 degrees. Thuban was never a pole star.

The downward sloping shaft of Khufu's pyramid, reaching an unexcavated chamber below bedrock, is at an angle of 26.5 degrees, a nice coincidence with the lowest point Thuban's rotation in the sky.

The access shaft angle of 26.5 degrees is found from a slope of 2:1. This angle has nothing to

do with the elevation of the polar axis above the horizon, which is 30 degrees at the latitude of Giza. It is a convenient sighting measure for boring an extended passage. All pyramids since Seneferu used this angle, or a measure close to it, despite their geographic location.

The other pyramids differ from 26.5 degrees, even though built at the same time and at the same latitude. Khafre's is at 25.9 degrees; Menkaure's is at 21.6 degrees. Pyramids for the next thousand years, in fact, all have access shafts which vary from 22 to 28 degrees. Let me note that a half degree is equal to the diameter of the Moon in the sky. The access shafts of the three Giza pyramids pointed to locations in the north sky differing by 8 diameters of the Moon.

And what is the point of this? Perhaps I have missed something in my close reading of "The Cosmic Serpent." The justification of a new dating system perhaps? Maybe it is to show that they also are researchers on par with Velikovsky, who also identified a similar (but later) 400-year gap. I see absolutely no other reason for this diversion. If, however, they were out to demonstrate their abilities as astronomers, they missed the boat.

This diversion has the flavor of Robert Bauval and Adrian Gilbert's book *The Orion Mystery* (1994). But they use an air shaft instead, and as a result place the construction date in 2600 BC.

... a new date of 1369 BC for the Exodus

Of course, since the date of the Exodus is still in dispute today, even the very event, Clube and Napier are free to make yet another suggestion. What enters the equation is, however, about as hokey as can be imagined. We start with the following assertion..

[p 237] [1369 BC is justified on the basis of Greenland ice core data] *"Many historical [volcanic] eruptions have recently been dated from Greenland ice cores, one of them being the Thera eruption in the Aegean Sea which some have associated with the end of the Minoan civilization [at 1388 BC]."*

I should point out that the 1369 BC eruption of Thera has been shown to be incorrect by Peter James in "Centuries of Darkness" (1991). See his website, [\[http://www.centuries.co.uk\]](http://www.centuries.co.uk). Clube and Napier continue..

"Several layers of volcanic tephra from cores taken from the eastern Mediterranean sea bed have also been examined recently. These can be dated, and for the Minoan ash a date of 1390 BC has been found. These absolute dates differ greatly from the radioactive carbon dates of the Thera event adjusted to the standard scale, the latter being assumed to be in agreement with conventional Egyptian chronology. On this scale, the date is 1720 +/- 50 BC and there is an implied discrepancy of 330 +/- 100 years in adjusted carbon dates of this epoch."

"These independent lines of evidence seem then to lead to the same conclusion: there is a major error in the standard chronology...."

The "absolute dates," "radio carbon dates," "standard scale," "conventional chronology," and "implied discrepancy" of the "volcanic tephra" and "Minoan ash," in the above paragraph make absolutely no sense.

But what is the point of all this? The point is that this claim will allow Clube and Napier to furnish a new chronology for the past and date the Exodus to 1369 BC, rather than the well-established dates from 16th-century chronographers -- 1492, 1493, 1495 BC -- and even Josephus in AD 100. And the point of the new chronology will be to fit the dates numerologically to other dates and periods that they have discovered. Numerology is everything here; it has a certain charm, like reading an electric meter.

[p 255] *"It is only speculation at the moment but the near-coincidence in time between the Thera eruption, the decline of Minoan civilization and our proposed date of Exodus [1369 BC] suggests that these events may have been interrelated."*

The speculation remains, although over the next pages this embarrassing admission is forgotten.

... megalithic missionaries

Clube and Napier next take time to discuss barrows and henges.

[p 259] *"In France, Ireland, and Britain, the building of graves and cairns was a relatively small and local scale until about 2400 b.c."*

And they warn that..

"in this section, we use uncorrected carbon dates"

I don't think so. A look at the dates of the constructions at Carnac -- the mounds, barrows, the Grand Menhir, the five causeways, and the now sunken henges -- will show that most of the construction started one thousand to three thousands years earlier than 2400 BC (from 5800 BC). It was so long ago that the melting glaciers have raised the ocean to inundate some of the works near Carnac.

They quote one author [E. Mackie "The Megalith Builders" (1977)] who refers to the activity in "2400 through 2000 b.c." as..

[p 259] *"...an astronomy-practicing theocracy, exactly paralleling, it seems, the main phase of pyramid construction in Egypt [although the authors date the Giza pyramids to 2196 -- 1687 BC]. Accurate surveys of many stone circles in Britain by Thom*

[Alexander Thom, not referenced, who published in 1951 to 1967] *and others have been interpreted to show that a proportion [portion?] of them could have been used as solar and lunar observatories."*

"Could have been" leaves a lot to be desired. The "others" which might have suggested astronomical alignments is Gerald Hawkins, who found so many astronomical alignments for Stonehenge that it became a joke. I should also point out that the date range "2400 BC through 2000 BC" is not valid. Most of the megalithic activity came to a sudden 300 year halt worldwide after 2400 BC. After that date only single inhumation barrows are constructed.

The authors have more to say about henges, some of it inaccurately rendered, including a misreading [p 260-261] of William Stukeley who wrote about henges 250 years ago, in AD 1740.

[p 261] *"... it is now known that their constructed shapes [of henges] were evolving from purely circular amongst the earliest to elliptical and egg-shaped configurations among the latest. The reason for this development of patterns are not yet understood."*

The phrase "not yet understood" is typical in the sciences for "we do not know" -- as if they will sooner or later figure it out. The evolution of circular to elliptical (noted by Alexander Thom, "Megalithic Sites in Britain" 1967) has no bearing on anything that follows, except perhaps to suggest that the people of these regions became more stupid over time, and thus proposing that perhaps they would have need for outsiders to set them straight. In fact, the earliest circular shapes of placed stones, at the ends of the rows of standing stone causeways at Carnak, are elliptical, not circular. But these date from 5000 to 4000 BC. Many of the henges date from before 3000 BC. All the later henges are circular.

[p 260] *"The plan layout of the early earthworks at Stonehenge, for example, was a circle out of which led an avenue toward the eastern horizon."*

Like the elliptical henges, this is another data point which connects to nowhere. What is the point of mentioning this? The avenue, in fact, leaves the henge in the northeasterly direction (not "the eastern horizon"), then turns east, and after a while turns southeast to meet the river Avon.

[p 265] *"The advance of the civilization prior to 2400 BC shows much more the signs of a steady infiltration of a new culture into a previously existing primitive society. MacKie [sic, E. Mackie is meant] leaves the sources of this culture quite open, but suggestively deplores the lack of solid evidence for any infiltration or diffusion from the east."*

"The Phoenicians seem perhaps the most likely candidates, but the evidence unequivocally focuses attention on the Atlantic front."

What does "focuses attention on the Atlantic front" mean? The Phoenicians migrated to the

western Mediterranean in ca 800 BC, not in 2400 BC.

"We will not speculate further but leave the reader with the inevitable thought: that around 2400 BC, the time of the Flood if our analysis is correct, saw the arrival of what seems to have been a stream of more sophisticated immigrants very conscious of what caused the calamity they survived and who rapidly took over the administration of the Atlantic border."

I have broken the original paragraph up into three parts, so that the reader can have a feel for how two professional astronomers blather like drunken sailors with wild tales, and otherwise make little sense.

The notion of invaders, called the "Beaker People" (and the "Battle Axe People") two centuries ago, has been removed from archaeological theory in the last century. This is "analysis?" Next, of course, there will be reference to Plato and Solon, and maybe to Atlantis?

Having suggested that the intruders were Phoenicians.... But wait, this was a favorite *cause célèbre* early in the 20th century: Phoenicians as missionaries from the east who proselytize the western European coastal tribes to a religion of large stones and beer. I have already discussed this elsewhere in this text.

Now the two are tied together.

[p 265] *"If short-period comets were indeed sky-gods, and the comet which we are now calling the Cosmic Serpent came spectacularly close to the Earth at intervals, then the desirability of predicting the returns would be clear: astronomy would grow out of theology. Obviously no extreme or exclusion claims can be made for the role of comets, as agricultural and navigational requirements provide their own impetus for observing the heavens. Nevertheless...."*

Give me a break! Astronomy and agriculture? Nevertheless, the argument is not sustained. The suggestion that Phoenician missionaries, who were traders and merchants and interested in little else, induced the coastal French, British, and Irish tribes to build huge "observatories" when a few sticks in the ground would have done the same, is just plain nonsense. Why did 20-ton rocks have to be set up in circles, again and again and again, to look at the incomprehensible stars? What would possibly signal a return of the flood? Having experienced one flood, why, indeed, was there even the suggestion that a flood would ever return again? How dumb is it to believe that?

... calendars are conformed to their needs

Next the Maya Tzolkin is disassembled to their use..

[p 266] *"It happens that twice 260 days [the Tzolkin cycle] is the mean interval between oppositions (i.e. the synodic period) of any object in a direct orbit whose orbital period is 3.35 years. This is remarkably close to the orbital period of comet Encke."* [which is 3.30 years]

Not all that "close."

[p 267] *"Now 73 periods of 260 days equals 52 years almost exactly [51.96 years, 13 days difference]: no smaller number of these periods gives a whole number of years so closely."*

The above totally ignores the relationship between the Tzolkin and the Haab calendar in Mesoamerica, where there is an **absolute** coincidence -- exactly to the day -- between 73 Tzolkin cycles and 52 Haab cycles. A Haab cycle is a 365-day year after 747 BC (exactly), and a 360-day year before 747 BC. Clube and Napier seem to have missed this entirely. I suspect they know nothing about this subject except what they may have read somewhere about 260-day calendars in Mexico.

[p 267] *"European and Asiatic calendars were unquestionably lunar and solar and tied to agricultural needs."*

They were certainly lunar after 1492 BC, but only some were solar. None of them, though, none at all were "tied to agricultural needs." Farmers do not need a calendar to plan farming. They need to take note of the weather. Farmers would be poorly assisted by calendars. The calendars of antiquity were primarily, emphatically, and universally for the purpose of religious observances.

By Classical Greek times the calendars were given over to tax collection, initially also a religious function. They became fiscal administrative calendars. Which is why there were dozens of differing calendars in use among the Greek city-states. This happened to Rome by Republican times also. There was no coincidence with seasonal agricultural tasks. Julius Caesar was lauded in 40 BC for rationalizing the calendar which had been altered repeatedly by the Senate, and which had become completely out of sync with the seasons. Egypt by Ptolemaic times uses two (or more) calendars, one religious and administrative, another that was seasonal, and thus agricultural.

[p 267] [early Roman calendars quoted as:] *"... twelve months plus extra days to make up a year of 354 days", and "a year of ten months and 304 days, which makes no sense in terms of agriculture or planetary movements. As it happens, four such years amount to 3.33 solar years."*

The authors are desperately reaching. I am not sure where these Roman calendars came from, unless mandated during late Republican times for tax collection purposes -- in which case they are temporary fiscal calendars. The authors then suggest that four of "these" make up a

3.33-year period, even though the Encke period has previously been declared as 3.30 years. The paragraph continues..

"The number four seems arbitrary but ... the Greeks ... [later] set up a twelve-month year, they also chose to celebrate a major event [not mentioned, but it is the Olympic games], whose primary symbol was the torch of Olympus on a four-year cycle. Speculative though this is, the numerology is sufficiently striking to suggest that a deeper investigation of these early calendars might be rewarding."

I think not. I will consistently claim that calendars can be justified in terms of the number of days in the year (which was not invariant), plus a large measure of conservatism. All the calendars of antiquity can be rationalized on this basis, not on numerological notions.

The authors, by the way, hold "Olympus" to be the name of a comet, and "Zeus" too. "Speculative though this is," it is even more striking to suggest that readers of this book take all this drivel in without question.

A look at what we have at hand as a calendar since 747 BC will indicate that there were no "extra days to make up a year" for Rome, but it requires knowing that the Earth's orbit, and thus the year, was different in the past. The calendars of antiquity then assume an even more "striking numerology."

... the dark ages of Greece are affirmed

[p 181ff] [Re: Homer] *"The Greeks themselves also systematized a mass of local and particular mythology ... to form the mythological prehistory leading up to the large-scale Dorian invasion and settlement of the Peloponnese around 1000 BC, the time also of the return of the Heraclids to Mycenae."*

Not to be picky, but there is no evidence of a "Dorian invasion" and the Heraclids are the sons of Hercules which is Mars. They were seen in the sky, not on Earth, and are properly placed in the 8th and 7th century BC, not in a "Dorian invasion" time of 1000 BC. The third generation returned in 761 BC to destroy much of the Peloponnesus. There is, in effect, no history in Greece before this time.

The chronology of Greece, in being matched to a faulty Egyptian chronology, has a gap from 1200 BC to about 800 BC during which time nothing happened, and civilization stood still for 400 years. Homer's fiction was written after 650 BC. Does Homer ever concern himself with a Dorian Invasion, when all of the "Iliad" takes place in 56 days?

But what is really amazing is that these Edinburgh astronomers missed an Encke moment, for the Heraclids who invade Greece are indeed the meteor swarm which Clube and Napier have been meaning to identify. So, of course, are the cattle stolen by Apollo, and the horse herds

driven off by Hercules.

... the flood of Noah based on 19th century data

[p 209] *"Not far below the level of the first royal tombs at Ur, probably constructed around 2500 BC, archaeologists have discovered material evidence for a vast flood. It has been confirmed that there exists throughout the extent of the Tigris-Euphrates valley, a clay deposit several meters thick."*

This is simply not true. The "vast flood," at first thought to be the "flood of Noah," was an early 20th century notion (based on the excavation at Ur by Leonard Woolley), which was soon entirely disproven from the fact that it was very local and mostly absent elsewhere. Some British archaeologists still adhere to this. The "royal tombs" are Scythian Kurgans of the 8th century BC.

... the pantheon of Egypt, Babylon, and Greece

[p 180] *"... the Egyptian mythology placed him [Horus] on the prow of the solar barque, watching for the other great enemy of Ra, the Sun-god, namely Apepi [Apep], the god of darkness. Apepi was not apparently of Nut's family but was pictured independently as a snake or dragon, one of its roles being to eclipse the Sun. However he did this, he does not seem to have been related to the Moon-god, Thoth."*

That Apep was "not apparently of Nut's family" is entirely correct. Apep [Apophis] was the last remaining red-colored ring after the Absu fell, seen in the sky since 2349 BC. This is clear from how it made the star Sirius look red in antiquity. There are Mesoamerican references to this equatorial river in the sky also, still recalled in the 19th century. Clube and Napier perhaps also did not notice that there are few references to Apep in Egyptian mythology or iconography until Ptolemaic times because Apep never did anything. Spells to prevent Apep from attacking the Sun (the real Sun, btw) only occurs in one very late papyrus. Apep is not the snake Typhon. Ra, when Horus rides in his bark, is Jupiter, the "night sun." Thoth is Mercury, not the Moon.

[p 256] *"The aspect of Velikovsky's thesis that seems to have generated the most steam is his identification of the planet Venus as a gigantic comet that swept past the Earth before moving into its present orbit. Wildly improbable though this is for dynamical as many other reasons, there is no doubt that Venus did eventually assume a particular significant place in many early astronomies. If undue reliance is placed on the mythological rather than the scientific evidence, the absurd speculations about Venus [by Velikovsky] can at least be understood if not forgiven. How the confusion of blame between Typhon and Venus arose in some myths, assuming indeed it did, is obscure."*

I have discussed the "wildly improbable" dynamics. Could Clube and Napier get this any

more wrong? I do not think Venus came closer than 9,000,000 miles. It never left its orbit. Planets do not leave their orbits, although orbits change and reshape -- due to exterior electric field forces. Venus today still has a cometary tail. Velikovsky may not always have been completely correct, but his main thesis stands unimpeded by particulars. It is, in fact, a "concept indifferent to the details of its formulation." The mythological evidence is solid and overwhelming, and hardly absurd. Of course Clube and Napier use exactly the same mythological evidence to buttress their speculation, but selectively dismissing what they cannot use or comprehend.

... the windup

After an earlier wholesale dismissal of Velikovsky, he is suddenly given credit for one item. One item only, even though Velikovsky in this case has the agent wrong, and waffled on the exact date, as I have pointed out, and the effect, an Earth shock, which did not change the orbit of Earth.

[p 269] *"... if one takes a dispassionate look at the mythological evidence assembled by Velikovsky for example, setting aside his singular astronomy, one may conclude that there was a widespread anticipation of an encounter of the Earth with a comet or its debris in 687 or 686 BC."*

"This event could have been, as he suggests, a significant turning point in the history of civilization, releasing new visions of the nature of the gods, perhaps finally weaning man away from sacred calendars and the view of life in which the world progressed through catastrophe, fire and flood from one 'great year' to the next."

The year 687 or 686 BC for an uncertain electrical contact due to Mars (actually with Mercury) was also the only date that Velikovsky was uncertain of. The last part of the quoted text ("the great year") should be attributed to vd Waerden rather than Velikovsky. Velikovsky never made note of a "great year." The authors here have reference to "sacred calendars," something neglected earlier (when they were used for astronomical and agricultural services). In the following text (waiting for the next catastrophe in AD 0), however, the information is used to segue a "684 year period" into the derived date of 1369 BC.

But first, returning to more mundane claims of meteor impacts..

[p 270] *"Among the early [?] 'planetary' periodicities that emerged from the Babylonian observations was one significantly related to eclipses of the Sun and Moon for which van der Waerden has been unable to find any really satisfactory explanation. It was a period of 684 years. .. the figure occurs several times in astrological texts, yet there is no combination of known lunar periods capable of explaining it."*

The authors now suggest that Velikovsky's uncertain catastrophe of 687 or 686 BC is 684

years after their derived date for Exodus of 1369 BC; $686 \text{ BC} - 684 = 1370 \text{ BC}$. Similarly, $686 \text{ BC} + 684 = 2 \text{ BC}$, a date in the era when apparently another catastrophe was expected in the eastern Mediterranean region. The authors add to this some loose facts, for example, that a prograde motion of Mars repeats every 171 years, one fourth of 684 years, and that nine returns of Halley take 684 years. So what.

There was no "widespread anticipation of an encounter" in 687 or 686 BC. Instead, there was the delivery to the Sun of an absolutely stupendous plasmoid thunderbolt in 685 BC, which concluded 121 years of destruction in Persia, Anatolia, Greece, and Italy.

And there was no catastrophe in AD 0 or AD 2. The reasoning presented here -- the 684-year period -- might have served as a suggestion for a time interval, and could be used as an introduction to the "Sibylline Star Wars" texts of the first century AD.

There is no need to move the date of the Exodus up by 100 years. The time span of 684 years is easily derived from the accepted 1492 BC date of the Exodus and 806 BC, the first year that Mars blasted Persia, Anatolia, Greece, and Italy with lightning strikes (686 years). The periodic destructions lasted 121 years and came to an end when the "thunderbolt of Zeus" toppled Phaethon from his chariot in 685 BC. On what was thought to be the first day of spring of the following year (it had actually changed by 15 days) was seen a conjunction of seven planets -- what in antiquity was called the start of a "great year," even though these happen quite frequently. Nice coincidence: the world, recreated, started over. You will find the same notion in Vedic texts.

None of these various dates have anything to do with the Taurids, and the return of comet Encki. But without the single data point from Velikovsky, which the authors understand as the "widespread anticipation of an encounter of the Earth with a comet" in 687 or 686 BC, they would be unable to explain the supposed cycle of 684 years, even though in AD 2, at the completion of a second cycle, nothing happened.

I find this extremely selective use of data bothersome. As annoying is the constant juxtaposition of unrelated facts and suppositions, as if by their contiguity these go to prove some extended theory. There is no extended theory. The authors are entirely out of their field when it comes to calendars, archaeology, and mythology. They are reading school texts from the 1950s, and accepting these as the bearers of fact.

As a final note: What about Clube and Napier? people will ask. An interesting book of no substance. It is doubtful if meteors ever posed a serious threat in antiquity, or today -- the Tunguska event notwithstanding. I would bet almost all the "meteor craters" which have been found are the "anode marks" of electrical arcs, and not due to bolides falling from space. It is also amazing how few "craters" have been identified on the surface of the Earth. The few date, in fact, to millions of years ago, not to the time of the Exodus.

On the other hand, meteor clusters are not to be neglected. As I have shown, the early

European Cro-Magnon were absolutely obsessed with passing comets for some 20,000 years. They appear still during the 300-year period after 3067 BC when Mars cruised close to Earth, accompanied with a retinue of warriors (or cattle) to be recorded on the Palermo stone, and depicted on palettes and knife handles, and after 1936 BC, and then again in the 8th and 7th century BC. Most of the famed battles fought by the Egyptians in the intervening time span are meteoric troops seen in the sky. For 3000 years the Pharaoh consistently won every battle, until the very real Assyrians showed up after 750 BC, after which they consistently lost every battle.

There are still six asteroids closely following Mars. There are still dozens of comet streams which regularly intersect Earth's orbit today, sometimes with spectacular displays -- but all of it from the electrical flashing of dust -- dust, not rocks, not icecubes either.

Recovering the Lost World, A Saturnian Cosmology -- Jno Cook

Appendix I: The Canopus Decree.

\$Revision: 42.20 \$ (can.php)

Contents of this Appendix: [\[The Canopus Decree\]](#) [\[Sothic Dating\]](#) [\[Venus Rising\]](#)
[\[Sirius Rising\]](#) [\[Implications\]](#) [\[Further notes\]](#) [\[Endnotes\]](#)

The Canopus Decree

The *Canopus Decree* was found engraved on a block of stone, in two languages (and in three scripts), at Tanis in the delta of Egypt, dating to the year 239 BC. The *Canopus Decree* was introduced by the Greek pharaoh Ptolemy III, even though it reads as if mandated by the priests. It records an order to add one day every four years to the civil calendar, but the decree was never implemented.

The Egyptians at that time used a civil calendar of 365 days -- composed of 12 months of 30 days with 5 days added at the end. In addition, an observational lunar calendar was kept, alternating 29 and 30 days (averaging 29.5 days, the synodic period of the Moon), which was intercalated periodically, since it ran 11 days short of the solar year. A third seasonal calendar was also kept, starting sometime in July or August with the inundation, or expected inundation, of the Nile.

The *Canopus Decree* of 239 BC first introduces a new feast day honoring the pharaoh, then states when the New Year is celebrated, and that the rising of "Sothis" moves one day every four years.

"At present it occurs in this 9th year [of the reign of the pharaoh Ptolemy III] on the first day of Payni, in which month is celebrated the festival of New Year... . But as the case will occur, that the rise of Sothis advances to another day in every 4 years, the day of the celebration of this feast, shall not pass along but it shall be celebrated on first day of Payni and the feast shall be celebrated as in the ninth year."

The decree then states that one day will be added to the civil calendar every four years:

"But that these feast days shall be celebrated in definite seasons for them to keep for ever, and after the plan of the heaven established on this day and that the case shall not

occur, that all the Egyptian festivals, now celebrated in winter, shall not be celebrated some time or other in summer, on account of the precession of the rising of the Divine Sothis by one day in the course of 4 years, and other festivals celebrated in the summer, in this country, shall not be celebrated in winter, as has occasionally occurred in past times, therefore it shall be, that the year of 360 days and the 5 days added to their end, so one day as feast of Benevolent Gods [the pharaoh and family] be from this day after every 4 years added to the 5 epagomenae before the New Year, whereby all men shall learn, that what was a little defective in the order as regards the seasons and the year, as also the opinions which are contained in the rules of the learned on the heavenly orbits, are now corrected and improved by the Benevolent Gods."

[\[note 1\]](#)

"Sothis" in this translation (from the Egyptian text) is used both for the planet Venus as well as the star Sirius. "Sothis" means "brilliant" or "blazing," and could be applied to Sirius as well as Venus. Venus at this time no longer had a visible tail. The Greek text clearly reads "the star of Isis" for "Sothis." It has been suggested that this use of "Sothis" refers to Venus, especially since the Egyptian text reads "the divine Sothis." But the Greek text was primary, since the decree was composed by the pharaoh's staff, who were Greek. The Alexandrian Greeks never seriously learned hieroglyphics. I doubt, anyway, that Venus was meant.

Velikovsky states that Pliny identifies "the star of Sothis" as Venus. The identification of the star Sirius as "the star of Isis" is an equation found already in the Persian *Zend-Avesta* of the seventh century BC. References to Sothis occur in the earliest Egyptian funeral texts, dating back to 2345 BC. What relationship does Sirius, a star, have with Venus, a planet?

The misidentification of "Sothis" with the star Sirius, made by many archaeologists and historians, when it could equally refer to Venus, should be apparent from the context of the text of the decree. Venus moves one day in its heliacal rising every four years. Sirius does not move "one day every four years."

On the other hand, seen from the vantage point of the Egyptian 365-day calendar, Venus did not move in the calendar. Sirius moved a day every four years, as did all the other stars, and even the solstices and the equinoxes.

Sothic Dating

In AD 1904 Eduard Meyer of the Berlin School of Egyptology devised a theory of Egyptian chronology based on the 360-plus-5-day Egyptian calendar and the star Sirius. Meyer proposed that the *Canopus Decree* spoke solely to Sirius, the Dog Star, and proposed that the Canopus Decree directed the use of the heliacal rising of Sirius as a New Year day, abandoning the practice of a short 365-day year which slipped backwards against the seasons.

This was correct, but Meyer further proposed that in the past the Egyptians had used a 365-day civil calendar which moved a quarter of a day every year with respect to the previous year, so that after 1460 years it would be back in the season and on the day (and seen against the same background of stars) that it started to drift from (if the year also had remained at 365.24 days). The 1460-year period became the "great year" of the Sothic cycle. Meyer's theory of Sothic dating depended on off-hand comments written 500 and 600 years later than the Canopus Decree.

I should point out that there was a notion of a "great year" current in Roman times. But no one seems to know what a "great year" was, how long it was, or where it came from. My guess is that the concept of a "great year" dates from the astronomical year 684 BC when all the planets were in the sky at the date of the vernal equinox. This has nothing to do with Meyer's Sothic cycle.

Sirius Rising

"... a veritable linch-pin of his Sothic theory was the combined classical evidence of Theon of Alexandria (5th century AD), and the Roman author, Censorinus (3rd century AD)."

"Meyer believed that the development of a significant relationship between the heliacal rising of Sirius, and the historical dates, had become possible due to a statement made by Censorinus (in AD 238) that New Year's Day for the Egyptians in circa 139 AD had fallen on the 21st of July. It was on that day that the bright star Sothis was supposed to have made its annual appearance."

This is from Damien F. Mackey, "The Sothic Star Theory of the Egyptian Calendar" (1995), originally at specialtyinterests.net/sothic_star.html.

The "evidence" of Theon of Alexandria is a remark that a "great year" ends in AD 27. In fact, an ephemeris will show that on January 23 of AD 27, Julian, a "Great Year" is signaled by having all the planets appear in the sky at the same time. This happens frequently, but it was not the "great year" Meyer had in mind. Other researchers have claimed that a "great year" is simply a lunar calendar year of 13 months -- the observational lunar calendar with one additional intercalated month. But for Meyer the mention of a "great year" suggested the completion of a 1460-year period. Meyer thought that any mention in Egyptian records of the remote past of "Sothis rising" could be used to accurately date events.

Censorinus does mention a period of 1460 years, but does not relate it to the annual appearance of the star Sirius. Instead he ties it to a supposed "Supreme Year" of Aristotle, when all the planets return to their starting locations in the sky. This is said to signal a major catastrophe on Earth.

Some have identified the date in question in 239 BC as July 17-19 Gregorian, and others are certain that Sirius should have risen heliacally on July 21, Julian.

Sirius is the brightest star in the sky, but it is unlikely that the heliacal rising of Sirius, or, for that matter, any other star, could be used as a clear marker of the start of a calendar. During heliacal rising Sirius only achieves a magnitude of 4.5 at the horizon -- a very dim star at best. It is much brighter a few days (and degrees of elevation) later. Once it is some ten degrees away from the horizon, it reaches its magnitude of 1.9 -- shining then as the brightest star in the sky, with only Jupiter and Venus being brighter yet.

The Egyptians were also hindered from seeing the east horizon from the Nile valley by the highlands bordering the river. "Heliacal rising" is not well defined as a result, and never easily detected. The Egyptians, in fact, never took much interest in rising stars, although they charted three-dozen groups of stars for the purpose of timekeeping during the night.

The Sothic Dating theory has been abandoned in practice, for it simply makes no sense as a calendar for a people, but not before finding its way into many textbooks where it has become solidly ensconced as indisputable fact. Meyer's attitude in 1904 is a remnant of the medieval European confidence in "the wisdom of the ancients." Meanwhile, it has made a mess of Egyptian dating.

Victor Clube and Bill Napier write, in *The Cosmic Serpent* (1982):

[p 228] *"... although archaeologists have come to depend totally on the validity of the [Sothic] cycle, it remains to this day a very disturbing fact that there is no known reference to the Sothic cycle in Egyptian texts."*

Except, of course, for the occasional reference to the rising of Sothis. Peter James writes, at [\[www.centuries.co.uk\]](http://www.centuries.co.uk):

"The Sothic theory depends on a number of assumptions which do not stand up to close scrutiny. Since our first published criticisms (James, et alii, 1987, 71-74) there has been a sea-change in opinion as to the reliability of this astronomical dating."

"As there are no longer any reliable astronomical fixes, Egyptologists have, by and large, abandoned their reliance on Sothic dating - although they have been rather slow in admitting it in public."

I would suggest that Sothic dating never existed. The Egyptian 365-day calendar, used at a time when the year was 365.24 days long, could only have been in effect since 747 BC, or perhaps adopted after 685 BC or some other date. It was designed to keep the risings and settings of Venus perfectly in tune with the religious calendar, even though all other celestial events would slip into the future. The 365-day calendar included 12 "months" of 30 days, which had nothing to do with the period of the moon, and five days which were not in any

month. The basis of its use was in the previous calendar, in effect before 747 BC, when the year was 360 days and the month was 30 days long. The rising of Venus on its 8-year cycle, and the yearly rising of Sirius, and all other stars, and even the equinox and solstice dates, kept perfectly in sync with the 360-day calendar.

The Egyptians, and apparently other people of the Eastern Mediterranean, had long ago developed a concept that every God and every being was represented by a star. The star of Venus was Sirius. Both Venus and Sirius were the most brilliant objects in the sky. Sirius was also important because it traveled in an arc across the southern skies, framing the Nile which flows from the center of the arc. Before 685 BC, the travel of Sirius along this arc would have started almost directly east and ended almost directly west. It was the major marker for navigation of the Mediterranean -- easy to see and easy to use.

After 685 BC Sirius rose in the southeast instead, and rose late in July. Its appearance in the mornings before sunrise signaled the flood of the Nile, which started sometime in late July or early August. Considering that the start of the inundation of the Nile was the major event of the Egyptian agricultural calendar, the rising of Sirius in late July would be a significant marker date for a calendar -- at least, for an agricultural calendar.

Sirius would rise about July 17 (Gregorian), first seen along the eastern horizon, and rise earlier each night thereafter (seen higher in the sky at nightfall). By December 11 Sirius would rise in the east a few hours after sunset and reach the western horizon just as the Sun was rising in the east. Over the next five months Sirius would be seen progressively further west in the sky at nightfall and set in the west earlier. [\[note 2\]](#)

Venus rising

Venus is seen above the eastern horizon before sunrise as the brightest object in the sky for a period of about 8 to 9 months -- five times out of every eight Earth years (and similarly five times in the west). At first Venus becomes visible just before sunrise. Over the following weeks it is seen earlier and higher up in the sky, but never more than about 40 degrees from the horizon. After climbing in the sky for 4 months, it would start to appear lower, to eventually disappear behind the rising Sun, and then (after 50 days) appear in the west for about 9 months, following the same sequence of initially appearing at the horizon, and then appearing higher in the sky every night. After disappearing in front of the setting Sun, it would reappear in the east again after about 8 days. The five periods of eastern and western visibility rotate through the year, only to repeat exactly at the end of 8 years, but displaced by two days on the seasonal calendar. That's how things happen today. [\[note 3\]](#)

Before 685 BC Venus had looked much brighter on its heliacal rising than Sirius ever would (but no longer in 239 BC), because of the spreading plasma tail which was directed towards Earth as Venus was passing in front of the Sun, making it probably half the size of the Moon. Before 685 BC the rising of Venus could not have been missed. It would also have been much more brilliant than any star in the sky. Using a Venus calendar (which a number of other nations also used) made sense. Every 8 years Venus would rise in the east against a backdrop of the same stars as 8 years earlier, but two days earlier in a seasonal calendar.

[*Image: Heliacal rising of Venus in antiquity. Image in public domain.*]

As it moved past the Sun, the brilliant tail would swing from pointing directly toward Earth (or parallel to the horizon) to point directly up -- the "going up of Sothis," as Egyptian texts describe a phenomenon which we tend to interpret as "heliacal rising," and using the feminine ending for Sothis ("spd.t") to signify Isis, that is, Venus. Over the following days the tail would grow in length and become visible earlier before sunrise while Venus rose higher in the sky. If the ancients needed a spectacular periodic sign for the regulation of the year, which would they select? It is true that at the time of the Canopus Decree the tail had possibly not been seen since 685 BC and certainly Venus was much reduced in brilliance from the remote past. Perhaps it was time for a change.

Velikovsky offered the suggestion (I think correctly so) that the first reading of "Sothis" is indeed "Venus," but that later references are to Sirius, and suggested that the priests were attempting to nail the calendar to the rising of Sirius.

The earlier 360-day calendar was most likely related to the Venus cycles, for before 747 BC the synodic period of Venus had been 600 days. That means that the heliacal rising of Venus would fall on the same days of the seasons, and, although the rising and setting dates would vary during this period, every 8 years the same cycle would repeat. This was true even though Venus may still have been on an elliptical orbit, as was the Earth, because ellipticity does not affect the orbital period. Before 747 BC, the New Year's Day of the 360-day calendar might have been initiated, not by observation of the equinox, but by the heliacal rising of Venus -- on an 8-year cycle. The count of days, or, more likely, the count of 12 months of 30 days, would bring New Year's Day around again.

Already in the first dynasty, Venus was called "Opener of the year" and "Lady of the new year." It could be suggested that at that time Earth and Venus would have identical synodic periods. Venus had always been used as a calendar marker.

Implications

It should also be obvious that it really does not matter. It makes no difference if the original calendar was timed to the heliacal rising of Venus or not. In either case the Egyptians were burdened with a shifting administrative (civil and religious) calendar -- a calendar which did not account for leap years. The Zapotecs, Inca, and Maya used the same Venus calendar, but the Zapotecs and Inca added a leap day every four years. The Maya, like the Egyptians, did not. Julius Caesar added a leap day to the Roman calendar in 40 BC.

By the way, as Velikovsky points out, in later years the pharaohs were required, before accession, to swear not to change the calendar or add a day, in a ceremony performed, significantly, in the temple of Isis (Venus). This makes it look as if the calendar reform was rejected by the caucus of priests and perhaps especially those outside of the delta. It was not a matter of calendars; it was about disturbing the sacred feast days. Historians seem to forget the importance of religious celebrations -- the very heart of calendars.

The imposition of the Julian calendar by Augustus in 23 BC resolved the issue, and in effect implemented the *Canopus Decree*. With the Julian calendar the year in Egypt started on August 29 (Augustus's birthday). This date was close enough to the start of the less formal agricultural calendar, and close to the intent of the *Canopus Decree* in 239 BC, to satisfy nearly everyone. Upper Egypt, outside of the control of the Romans of the delta, retained the Venus calendar for an additional six hundred years.

The old Roman calendar had run into the same slippage because it was also based on an exact count of days, and was additionally altered by the Roman Senate for tax collection

purposes. Caesar resolved the discrepancies in 40 BC by moving the starting date back two months (supposedly to the date of the culmination or heliacal setting of Sirius), and introducing a leap day to be added every four years. When Rome took over Egypt, Augustus was faced in 23 BC with the same problem with the Egyptian calendar, which had slipped an additional 54 days since the *Canopus Decree* had been rejected in 239 BC. The year now started at the beginning of May. The selection of August 29 as the starting date, lopped a full four months off the Egyptian calendar in the transition year. What Julius Caesar had done, Augustus could do also.

Further Notes

If we can use the year 239 BC with an ephemeris, without making the adjustment for the error of Eastern Mediterranean chronology, then in 239 BC at the vernal equinox, Venus rose with the Sun. Indeed, the year 239 BC would have completed a "Great Sothic Year" as devised by Eduard Meyer -- if only Venus were to be understood as representing Sothis, and a "Great Year" as representing 1460 solar years. It was an auspicious year to request a change in the calendar.

But it was not so. The year 239 BC in Eastern Mediterranean chronology is actually 244 BC (-243 astronomical), and nothing of the sort happened. Instead, Venus set with the Sun at or close to the solstice. It would reappear in the west, just after sunset, 90 days later, in time with the autumnal equinox.

The decree was released on 7 Apellaios, a Macedonian name for March, says the translator S. Birch, in *Records of the Past* (1876), which he further identifies as 17 March. The phrase "after the plan of the heaven established on this day," says as much. Velikovsky read that phrase in the *Canopus Decree* as meaning, "the change in the skies since 747 BC," but I don't think so.

It might mean, specifically, and as developed in the speculation below, that only in this year - 239 BC, actually 244 BC -- would New Year's day fall on a significant day of the calendar which would allow an easy change. The significant day would be the autumnal equinox, the day when the New Year had been celebrated in remote antiquity.

The suggestion, from the text of the *Canopus Decree*, that New Year had previously fallen in winter in the past needs also to be considered. This could only have happened after 747 BC, if the Egyptians had failed to add 5 days to the civil calendar, and had retained the 360-day calendar. This leads to a completely different analysis of the intent of the *Canopus Decree*.

We could, for example, assume that the Egyptians had stubbornly continued to use a 360-day calendar after 747 BC, losing $(747 - 685) * 5.24 = 324.88$ days up to the time of the Assyrian occupation, or $(747 - 525) * 5.24 = 1163.28$ days up to the Persian occupation -- more than three years in the last case. For either case, this certainly would suggest that the feast days

had shifted around the year, as the *Canopus Decree* claims -- "as has occasionally occurred in past times." I'm using uncorrected calendar years here because it does not matter to use these for this example.

It is, in fact, altogether typical of all people to not correct their calendars. Even in modern times, after AD 1582, many modern European nations refused to adopt the Gregorian calendar for up to 341 years (Greece, in 1923) -- much longer than the Egyptians had avoided an update. For the Egyptians the failure to amend the calendar would mean that the calendar fell behind 5.24 days every year, so that the calendar would rotate through a complete year every 70 years. Although that may have happened in the past (the statement in the *Canopus Decree* could be hyperbole), by 239 BC the Egyptians were apparently using a 365-day calendar (rather than a 360-day calendar), which only fell 1/4 day behind every year.

That means that at some time after 747 BC the five days were added, but not the last quarter day. It may have been the Assyrians who brought the extra five days during their occupation in circa 685 BC, or the Persians in 525 BC. The Egyptians, whose civil and religious calendar assigned significant feast days to every one of the 360 days, were stuck initially, and made the decision to honor the birthdays of the five primary Gods on the extra five days.

The month "Payni" is the 10th month of the year, part of our June and July (mid-June to mid-July). That places the end of the 12th month (and the end of the calendar year) in mid-September. This suggests that in the past (before 239 BC) the autumnal equinox was used as the start of the year. That is not unusual, for nearly every nation on Earth had celebrated the New Year at the autumnal equinox since 2349 BC. [\[note 4\]](#)

The *Canopus Decree* suggests celebrating the extra day on the first day of Payni (after the five days which follow the end of the 360-day year). The first day of Payni (since it would fall in mid-June) would likely be the summer solstice, June 15 plus 5 days -- and thus about 90 days had slipped since the calendar was correct at the time of the fall equinox.

Whatever the extent of the shift was after 747 BC, it seems likely that the Egyptian religious calendar added the extra five days, but not the quarter day, directly after 685 BC, so that the New Year was again celebrated at the fall equinox, which before 685 BC fell on September 6th, and after 685 fell on September 21st (see my previous text on this shift). It is possible, however, that the Egyptians celebrated New Year at the culmination of the Pleiades, as many other nations did, which would have fallen on the Gregorian equivalent day of September 8th before the summer of 685 BC, and on October 8th after 685 BC.

At any rate, counting from 685 BC, when I think a revised calendar was likely imposed by the Assyrians, and adjusted for the change in the autumnal equinox in 685 BC (in the opposite direction), the slipped days to 244 BC (the year of the *Canopus Decree*), is **(685 - 244) * .24 - 15 = 90.84 days**. This is very nearly equal to the assumed 90-day lag mentioned above, placing New Year's Day on or near the solstice, and is close to or equal to the actual number of days between the solstice and the fall equinox -- 92 days from June 21 to

September 21.

The fact that the New Year's day was celebrated at the summer solstice in 239 BC (244 BC), and would continue to be if the leap day was added, is likely what was meant by "after the plan of the heaven established on this day." Although actually, what was probably meant was that the first month of the year would start in mid-September -- as it had always been -- even though the 5 or 6 adjusted days fell in mid-June, and New Year as a result was celebrated at that time. Note that the Guatemalan Chiapas also add the 5 extra days at an odd time of the calendar year, after their third 20-day month, with New Year at the winter solstice.

Note 2 --

In 239 BC, July 17, Gregorian, is July 21, Julian.

Since 685 BC, and until AD 400 or 600, Sirius had appeared red, since it fell behind the last band of the Absu at a culmination of 43 degrees. However, on first rising Sirius would miss being placed behind this equatorial ring, and thus appear white, but also very dim. Before 685 BC it traveled well above the Absu, just below the equatorial. At that time it would have been the brightest star in the sky, and white.

[\[return to text\]](#)

Note 3 --

For example, in the period starting with the year 2001, the following sequence of eastern rising will happen. After 8 years Venus rises in the east 2 days earlier in the calendar. Westerly appearances are not listed.

date of eastern visibility of Venus		

year 0	2001 March 22	- 2002 January 11
year 1	2002 November 1	- 2003 August 19
year 2		
year 3	2004 June 8	- 2005 March 25
year 4		
year 5	2006 January 11	- 2006 October 28
year 6	2007 August 19	- 2008 June 9
year 7		
year 8	2009 March 20	- 2010 January 9

[\[return to text\]](#)

Note 4 --

On the order of God, after 1492 BC the Israelites moved the celebration of the start of the liturgical year from the fall equinox, as it had been under Egyptian rule (and where the start of the civil year remained), to the spring equinox, or rather to the first full moon after. The Babylonians followed suit after 747 or 685 BC.

Note 5 --

Report on a talk by John Fermor, "A Revised Chronology for Egypt," given at "New Directions in Ancient History" Conference in London, September 1980, sponsored by the SIS, and quoted in *SIS Review* Vol. V Number 1 1980/81.

"He started from the proposition that in the 3rd century BC the Egyptians had a 365-day

calendar although the natural year was 365 and 1/4 days. In 26 BC the Julian calendar of 365 1/4 days was introduced into Egypt but the Alexandrian calendar of 365 days remained in use. By AD 139 there was a discrepancy of 41 days between the Julian and Alexandrian calendars for the date of 1 Thot, the Egyptian New Year's Day. In 165 years, there had been a shift of 1/4 day a year, as one would expect. On 1 Thot AD 139 the star Sirius rose heliacally; in 238 BC this event occurred on 1 Payni - a shift of 95 days in the Egyptian calendar in 377 years, again at the rate of 1/4 day a year. This correlation, Fermor argues, can be shown to hold good as far back as 521 BC, before which things become uncertain."

The calendar years are uncorrected for the 4-year discrepancy. so that Sirius did not rise on 1 Thot in AD 139.

Recovering the Lost World, A Saturnian Cosmology -- Jno Cook

Appendix J: Expanding Earth.

\$Revision: 42.10 \$ (exp.php)

Contents of this Appendix: [\[Pterodactyls\]](#) [\[Expansion\]](#) [\[S. Warren Carey\]](#) [\[Questions\]](#)
[\[Endnotes\]](#)

Pterodactyls

Ted Holden has expounded for years on the problems the early dinosaurs would have had walking and running, and most elegantly on the problems Pterodactyls with 30- and 50-foot wing spans would have had in lifting off the ground and flying. He offers no solution except to suggest that the force of gravity might have been lower in the age of the dinosaurs. Robert Bakker, a researcher and expert on dinosaurs, has proposed various bony ligaments which would lace the necks of the large dinosaurs to help hold up their heads. [\[note 1\]](#)

If gravity has changed since the age of the dinosaurs, it might have been due simply to the Earth expanding and becoming more massive. Expansion would increase gravity if the center of the Earth filled with new material. This is somewhat of a radical suggestion, since most people are not at all comfortable with the creation of matter from nothing.

In the 1960s oceanography came up with some surprises. First of all, it was recognized that the ocean beds were not filled with miles and miles of sediment, as would be the case if the world's rivers had been carrying silt to the oceans for four billion years. Instead it was found that the ocean floors were geologically new.

Expansion

The second surprise was the discovery of the Atlantic ridges, a series of parallel ridges which run mostly north and south throughout the Atlantic. The ridges show a series of parallel magnetic reversals of the top layers of rock, matching east and west from approximately the center of the Atlantic. Further research has found the same in the Pacific and Indian oceans, although of a more complex pattern.

Geological dates of the ridges also match from the center out. The oldest ocean beds are just

east of China, with smaller stretches just off the North American east coast and in the South Caribbean. These regions date from 180 million years ago -- from the Jurassic era (200 to 150 mya), the second era after the end of the Permian and the era of the giant dinosaurs.

[Image: Atlantic Floor Spreading. After Karl Luckert.]

It looked like the Earth had indeed been expanding, and in fact it looked like there were no oceans before the Jurassic. That means the original landmass, Pangea, the single landmass which had already been suggested as the parent to all of today's continents, must have covered all of the Earth at one time. The start of ocean floor spreading (as it is called) dates from after the first appearance of the giant dinosaurs during the Jurassic.

You can look at a globe and make some simple calculations. Subtracting the estimated average width of the Atlantic and Pacific from the current circumference of the Earth (25,000 miles, 40,000 km) gives an earlier circumference of about 12,500 miles (20,000 km). The Earth has roughly doubled in diameter.

Surface gravity is a function of the mass divided by the square of the radius of the Earth. The mass of the Earth, assuming no change in density for the new material, is a cubic function of

the radius. Thus gravity is linearly proportional to the radius of the Earth. As Earth expanded, gravity increased linearly in proportion. [\[note 2\]](#)

[Image: Pacific Floor Spreading. After Karl Luckert.]

Since the radius has doubled since the Jurassic, 200 million years ago, gravity has increased also by a factor of 2. The change in gravity is marginal over time spans of 10 or 20 million years (1 or 2 percent per million years), but certainly enough over 100 million years so that Bakker does not need to speculate about how rigid ligaments held up dinosaur necks, and Holden need not question the 50-foot wing spans of Pterodactyls. The really "giant" dinosaurs date to the Jurassic age, 200 million years ago, and the remaining "evolutionary data" fits: after each of the many extinctions, the large animals never returned in the same sizes -- gravity in each instance had increased significantly, and put the larger animals at a disadvantage. The first mammals of the later Tertiary period were also very large at first, and these disappear in turn. Plants went through a similar cycle, with only the climatically protected Sequoia as survivors. [\[note 3\]](#)

S. Warren Carey

S. Warren Carey in two books, *The Expanding Earth* (1976) and *Theories of the Earth and Universe* (1988), suggests that 200 million years ago (at the Jurassic) the Earth was only half its present diameter, and completely enclosed by Pangea, the single landmass which today has been torn to smaller pieces. Expansion of the Earth split Pangea, forming the current ocean basins in the process, which filled with water -- some as runoff of the shallow continental seas, most of it probably welling up from within the Earth. Ocean-bottom thermal vents and volcanoes spew out water and water vapor. The second book suggests that matter is being created in the center of the Earth.

Carey and his followers in fact suggest that the expansion is not linear (as implicit in my abbreviated formulation) but exponential -- that is, it is a function of the mass already accumulated. They say very little about gravity. Many of Carey's followers are not comfortable with his second book and are extremely reluctant to suggest the creation of new mass. The creating of mass does not contradict current physics, and is in fact a postulate of quantum theory. (Exception could seriously be taken with both of these statements.) But many people have serious philosophical problems with the creation of anything new out of nothing.

Before the Jurassic there were no oceans, only shallow seas located on the stretched-flat inland areas between mountain ranges. There may have been a southern ocean. This was also before the recent orogeny -- the set of mountains identified as the Alps, Himalayas, and the Rockies (the whole of the Cordilleras, which includes the Andes). Mountain ranges are clearly the result of a solid landmass crumpling as the radius of the substrate on which it rests increases. Mountains are thus hollow, and provide easy access to the surface for material welling up from the substrate. The large flat mid-continental basins are stretched areas, often with faults where the Earth shears (due to stretching of the landmass). The process of stretching landmasses and curling the edges (mountain ranges) can only account for some of the expansion. At some point the original single continent would rip and the fault would widen and fill with new material from within the Earth. This clearly shows in a mapping of ages of the ocean crusts. The shapes of the continents are exactly what would be expected if the peel of an orange were to be forced onto a sphere of twice the original diameter. Wedge shaped areas would remain after the original peel started to crack.

Antarctica was originally attached to Northeast Asia (as fossils testify), and butted up against North America. Antarctica eventually was rotated and pushed to its southern polar location by the new ocean floors which welled up around it. Australia touched up against South America on one side (and marsupial mammals ended up in both continents) and Southeast Asia and India on the other. East Africa was up against India. North America was located against Europe on one side and Asia (with Antarctica still between) on the other, South America was against Africa. Europe had not tried to pull away from Africa yet. As you can see, this originally was a small globe.

Questions

Some questions remain. Is the Earth still expanding today? Even if this were so, it would be totally undetectable. Carey and others think expansion continues, at an increasing rate.

Did the expansion happen gradually or in spurts? Carey suggests a continuous exponential expansion. Exponential expansion would reduce earlier changes to less significance, that is, the expansion only became very noticeable after the Jurassic. Others have suggested, based on biological (evolutionary) considerations, that gravity may have increased in the period before the giant dinosaurs of the Jurassic and then have fallen again.

The bands of magnetic reversals detected in the east-west direction from the center of the Atlantic Ocean floor suggest sporadic expansions. The intensity of the reversed orientations are weaker compared to the normal orientation. It is possible that the reversals mark plasma contacts with Saturn, although the data for reversals of magnetic orientation are sporadic and do not seem periodic. The number of reversals increase in frequency about 35 million years ago (some 20 instances), and become much more frequent during the last million years. These last are recorded also in sedimentation layers in the Balkans, and thus may represent data not available for earlier periods as found only in molten rock.

Where did all that new material come from? It has been suggested that almost all of it was added as the fall of asteroids and comets, but an exponential expansion suggests an ongoing process more likely related to the mass already in existence (the volume of the Earth), rather than related to the surface area of the Earth. You might suspect, offhand, that the added mass came from Saturn as a transfer of protons. At any rate, it is an awful lot of additional mass. The mass of the Earth has increased seven-fold in the last 200 million years. This represents only a very small fraction of the mass of Saturn, somewhat around 1 percent. If the expansion were due to asteroids then the Earth would have been covered in miles-deep layers. [\[note 4\]](#)

Some researchers have agreed in concept with the idea of an expanding Earth, but not in scope. Some have suggested that only a 20 percent reduction in gravity would suffice to allow the giant dinosaurs and plants. But this does not match the additional circumference due to increased oceans, or the age of the ocean bottoms.

It might also be suggested that the Earth simply bloomed, that is, it became larger without gaining mass, like bread rising in an oven. But that would *decrease* gravity, not increase it.

Similarly, the plasma theorists suggest that gravity is a function of the electrical conditions of the Earth, and is perhaps affected by electrical fields exterior to the Earth. Again, this does not account for the dated ocean floors, the movement of continents, or the doubling of the Earth's diameter. It does, however, match my supposition that Earth became a planet of the Solar System, and thus affected by the electrical field of the Sun, after the Permian, 250 million years ago.

The landmasses of Earth and its ocean bottoms are distinctly different materials. De Grazia sums it up, with:

"The crust of Pangea was 'sial,' heavy in silicon and aluminum elements, as is the crust today. Its depth was uniform; at about 30 kilometers it developed, but very gradually, into heavier silicate magnesium mixtures ('sima')."

"... All the recent vulcanism, seismism, and crustal churning has added little to the sial, for the magma below is not provided with the materials for its manufacture."

"There is no evidence that the oceans have destroyed and buried continental material,

or could have, since the sial and its sediments are lighter than the sima of the ocean floor."

"The fossil marine beds that are found upon the land today, even high up in the Himalayas, are once-flooded land-beds or they are Pangean shallow water formations. They are the relics of deluges, tides and certain risings visited upon the world by post-Pangean catastrophes. There are few fossil marine beds laying conformably upon plutonic or basaltic sima."

-- Alfred de Grazia *Chaos and Creation* (1983)

For 3.9 billion years the crust of the continents has been floating on the substrate. Then some 200 to 250 million years ago heavier material from within the Earth started to well up to fill cracks which had started to develop. It is the spreading ocean floors that have moved the continents.

We can recognize unfilled cracks today. One runs almost the whole length of Africa and on into Southwest Asia.

Endnotes

Note 1 --

Ted Holden at [\[www.bearfabrique.org\]](http://www.bearfabrique.org) and Robert Bakker *The Dinosaur Heresies* (1986).
[\[return to text\]](#)

Note 2 --

Gravity is expressed as $a = f (m / r^2)$

Mass is expressed as $m = f (r^3)$

Thus as the Earth gets larger, gravity increases because of the increased mass, but decreases because it takes us further from the center of the Earth:

$a = f (r^3 / r^2)$.

This reduces to $a = f (r)$

[\[return to text\]](#)

Note 3 --

There are suggestions also that gravity may have reduced initially during the time preceding the Jurassic, and then started to increase. This is mainly based on the rather compact proto-mammalian and proto-saurian animals of the earlier Permian period.

[\[return to text\]](#)

Note 4 --

If the diameter doubles, the mass will increase to 8-fold.

The earlier mass is thus:

$$(1/8) * 6 * 10^{24} = 0.75 * 10^{24} \text{ [kg]}$$

where $6 * 10^{24} \text{ [kg]}$ is the current mass.

The decrease in mass of Saturn (if Saturn was the source) is:

$$5.25 / (568 + 5.25) = 0.0091$$

which is about one percent of the mass of Saturn.

Recovering the Lost World, A Saturnian Cosmology -- Jno Cook

Appendix K: Venus and Epidemics.

\$Revision: 42.12 \$ (epi.php)

Content of this Appendix: [\[Spanish Flu\]](#) [\[Lockyer Observatory\]](#) [\[Diseases from Space\]](#)

[Image: Venus inferior conjunction with the new Moon intervening. Illustration by J. Cook.]

Spanish Flu of 1918

Venus has been implicated in the Spanish Flu epidemic of 1918 (the influenza pandemic). The suggestion is that the Sun, Venus, and Earth had been in line a month or two before the first, non-lethal, wave of the epidemic struck in the spring of the year. The second, very virulent, wave struck in late August and September, with a peak in late October.

The mechanism would be the solar wind's protons, which are focused by the very long tail of Venus's plasmasphere. NASA has identified the tail of Venus as "stringy" -- clearly identifying it as a Birkeland plasma current in high dark mode. The protons are traveling in excess of 2 million miles per hour (3.2 million km per hr) on reaching Earth. Although they

do not penetrate materials at that speed, they could damage cell structures and could cause changes in simpler forms, like viruses. As likely is that the increased inflow of particles changes the electrical characteristics of the upper atmosphere and allows a wider dispersion of viruses or bacteria.

[Image: Venus at Inferior Conjunction and the New Moon, February 11, 1918. From SkyGlobe 3.6.]

Venus passes between Earth and the Sun frequently (five times every 8 years), but since the orbits are tilted, the planets seldom are in a direct line with the Sun. Additionally, although the plasmasphere tail (coma tail) of Venus is very long, it does not quite extend to Earth. However, it is possible for the Moon to fall into place in such a conjunction, and provide a remaining path to the circuit. Such conjunctions are less frequent, generally happening two or three times in a row, followed by an equal time span where this does not happen.

The geometry is not as simple as suggested in the text above. Under normal conditions the Sun's protons which travel along the edge of the plasmasphere tail of Venus toward Earth would be deflected by the Earth's magnetosphere. The Earth's plasmasphere probably extends 20 Earth diameters into the space toward the Sun, (160,000 miles, 260,000 km). The Moon travels about 30 Earth diameters away from the Earth (250,000 miles, 400,000 km), and is likely to also have a plasmasphere "shadow" extending away from the Sun, toward Earth.

John M. Barry, in *The Great Influenza* (2004), suggests an unusual mutation of the influenza virus for the virulent second wave which struck in September and October of 1918. Barry suggests that the almost simultaneous appearance of the influenza in the United States can be accounted for by human contact, specifically by cross-country troop movements.

This is probably incorrect. Robert Fritzius presents data showing the appearance of the flu

throughout the United States and part of Europe in the span of seven days.
(<http://www.shadetreephysics.com/vel/iamds.htm>)

There was no inferior conjunction of Venus associated with the second wave which first appeared in September and October of 1918.

The next inferior conjunction after February 11, 1918, was on September 14, 1919. At that time Venus passed the Sun at about 5 degrees off the ecliptic. A new Moon only shows up a week and a half later, on September 23, 1919, at which time Venus was about 14 degrees removed from the Sun. A third wave of the influenza appeared four months later, in early February, 1920. But neither the second wave nor the third can be related to the movements of Venus.

After the Asian SARS virus epidemic of 2002 - 2003, I checked the Sun-Venus-Moon positions for the months before the outbreak was detected. An inferior conjunction of Venus directly in line with the Sun and our Moon had happened about three months earlier. That condition (a three-month "incubation") had also been noted for the Spanish Flu epidemic by other researchers.

A number of people have suggested a simpler process. They have suggested the existence of viral forms in the upper atmosphere of Venus. These would appear in Earth's upper atmosphere after being stripped away from the upper atmosphere of Venus by the solar wind, and their travel down the exterior of the plasmasphere tail. I will return to this further below.

Bob Fritzius has tracked the inferior conjunctions of Venus and pandemics for years, and comes to the same conclusion, and presented this evidence in a paper to the AAAS in 2002. See

Lockyer Observatory

Earlier research by Donald Barber at Lockyer Observatory in England, reported in *Perspective* Volume 5 (1963), had shown unidentified bacterial contamination of photographic plates exposed (to the night sky) between 1936 and 1961 followed a pattern of appearing 30 days after the inferior conjunctions of Venus. The bacteria were picked up (apparently) during film processing, and were found in the local spring water supply (used in processing). Their appearance followed a wind from the north, and local rains.

The description by Barber suggests the well-known condition, known to photographers who process film as "flying saucers," which appear in the sky when a water droplet remains on the film during drying. Barber writes:

"At the height of each major 'invasion' irreparable damage to freshly processed spectrographic plates was caused by numerous quasicircular craterlike defects (0.05 to

0.25 mm in diameter) from the centre of which the silver deposit had been eroded, and transferred to the perimeter. In a badly affected 1/4 plate negative some 5100 of these craters could be seen at low magnification (x15). In several instances the photographic film was completely liquefied and was seen to slide off the glass base intact."

The "transfer of silver to the perimeter" happens with water drops left on film also. The water drop swells the emulsion, causing the silver to move up, which is relocated to the edge when the emulsion dries and flattens again. But I have never seen "craters," nor have I ever seen film emulsion simply slide off its base. (I teach photography.)

[Image: Sunspots and Venus inferior conjunctions from 1910 through 1990. After Bob Fritzius.]

[In the chart above:

- Sunspot activity is shown as the red curves,
- Inferior conjunctions of Venus are shown regularly spaced lines,
- Invading bacteria are shown as the other bars,
- Pandemics are shown as "P".]

Because the damaging bacteria appeared in each case about 30 days after an inferior conjunction of Venus, and after northerly winds (actually winds from the northwest) and rain, Barber assumed that the bacteria entered the Earth's upper atmosphere (at the aurora borealis) with the solar wind after it passed by Venus. The 30-day delay is about equal to a terrestrial wind speed of 15 miles per hour (24 km per hr) from the auroral region.

Barber further notes that these events only occurred nine times in a period of 25 years. Each followed an inferior conjunction of Venus and a simultaneous "geomagnetic storm," that is, an auroral display. Venus reaches inferior conjunction every year and a half. Bob Fritzius has plotted both the Venus inferior conjunctions and sunspot activity against the bacterial invasions. See below.

Sunspot activity -- an index of the electrical activity of the Sun -- is difficult to relate to the bacterial invasions. Some pandemics are also shown, but also do not seem to be closely related to sunspot activity. Notice also that in some years nothing happened.

Except in a few cases, the bacterial invasions all follow directly on the inferior conjunction of Venus -- shown as red lines -- and at times seem to "hold over" for a period afterward.

In the chart below I have listed the inferior conjunction of Venus for the period of 1930 through 1961. For each of the inferior conjunctions I have listed if a new Moon appeared at the time of the conjunctions.

The date of the new Moon was often a few days removed from the "official" date of the conjunctions, since the calculated date is taken as the moment Venus crosses the meridian of the location of the Sun in the sky.

My conclusion is that an intervening Moon is needed for the electrical contact to Earth via Venus. Because the phenomena at Lockyer Observatory are dependent on the weather (as well as, apparently, on the freezing temperatures of winter), the failure of the phenomena to appear in some years does not depend solely on the inferior conjunctions of Venus. But the opposite can be tested: if the inferior conjunction does not coincide with a new Moon, the invading bacteria will not show at all.

This is borne out by the table above, where the absence of a new Moon is marked as "NO" and is also the index for the absence of bacterial infections. There are four exceptions in

addition to 10 correlations:

Inferior Conjunctions of Venus, 1930 -- 1961		
inferior conjunction dates for venus	new moon	bacterial infestation and additional notes
22 NOV 1930	yes	yes
29 JUN 1932	yes	yes
05 FEB 1934	yes	yes
08 SEP 1935	NO	NO
18 APR 1937	yes	yes
20 NOV 1938	yes	(June '38 and June '39)
26 JUN 1940	yes	yes (mild or holdover)
02 FEB 1942	NO	NO
06 SEP 1943	NO	NO
15 APR 1945	yes	NO
17 NOV 1946	yes	NO
24 JUN 1948	NO	yes; Mercury conjunct
31 JAN 1950	NO	NO
03 SEP 1951	yes	yes
13 APR 1953	yes	yes
15 NOV 1954	NO	NO
21 JUN 1956	NO	yes (new moon Jun 9, Jul 6)
28 JAN 1958	NO	(Jun '57; May '58)
01 SEP 1959	yes	(June '59; Apr, Jun, Aug '60)
10 APR 1961	yes	yes

- in June of 1948 there was no new Moon, but on this date both Venus and Mercury were in inferior conjunction;
- in June 1956 the new moon is 12 days early;
- in 1958 there is a 4-month delay; and
- in 1959 there is no relationship at all.

Diseases from Space

[Images: Fred Hoyle and Chandra Wickramasinghe. After Wikipedia and coseti.org.]

Fred Hoyle and Chandra Wickramasinghe in *Diseases from Space* (1979) claimed a correlation of the severity of influenza pandemics with sunspot activity, and suggested that viruses or bacterial spores could be transmitted to Earth from the tails of comets and with streams of meteors.

All four of these people are highly respected astronomers and their opinions are not to be neglected. Chandra Wickramasinghe and Jayant Narlikar followed up with another paper in 2001, claiming evidence of bacteria captured at altitudes of 41 km above the Earth. But a pandemic influenza is viral, not bacterial.

All four of these people also assume that the agents of epidemics, viruses or bacterial spores, come from Venus or at least are of extraterrestrial origin. Bob Fritzius writes:

"Compared to Earth, Venus has a negligible magnetic field. That means that the solar wind can disturb its atmosphere directly, and can blow away fractions of its upper atmosphere (including airborne particulate matter) in comet-like fashion."

This suggests the existence of life-forms in the upper layers of atmosphere of Venus, the only part of the planet which actually receives sunlight. At its surface, Venus is jet black. There is no light.

Followers of Velikovsky suggest that, if these life-forms exist on Venus, they will have come from Earth during the near approaches in 2349 BC and other dates to 1440 BC.

There were no "near approaches" as I have pointed out. I contend that Venus did not come to within 10,000,000 miles of Earth at these times. However, there have been periods in the past when the orbit of Venus extended past the orbit of Earth. Transfer of molecules (as ions) along the exterior double layers of plasmaspheres of planets is almost certain. We have clear indications of this for Mercury and for the Moon. This suggests that a transfer could have been made in the remote past, but not at these two dates.

If organisms, originally from Earth, could be delivered back to Earth, it seems likely that bacterial spores and viruses would eventually also be found on the Moon and Mars. This would cause considerable rethinking of our biological uniqueness in the Solar System.

Considering that the bacteria represent 80 percent of the biomass of Earth, and are found absolutely everywhere, it is quite possible that a bacterial transfer from Earth three or four thousand years ago could thrive in the Venusian upper atmosphere. It is highly likely that these forms would have mutated into many diverse species by now. But it is highly doubtful if bacteria would survive transport across 30 million miles of space.

Viruses are the products of bacteria. They do not engage in energy transfers, reproducing

instead entirely by intrusion into host bacteria (and other cells structures). Viruses could without a doubt survive a 30 million mile trip through space. Many forms seem to be almost totally indestructible.

John M. Barry, in *The Great Influenza* (2004), one of the best and absolutely engaging books on the 1918 epidemic, spends early chapters in the distinction between viral and bacterial action, which could be considered a primer on the subject, although inconclusive in the admission that we know almost nothing about viruses, where they come from, how they operate, or what their purpose seems to be.

... added note on the Swine Flu of Spring 2009

My first reaction to the Swine Flu outbreak of April 18 - 24, 2009, in Mexico City, was to check for a inferior conjunction of the Sun and Venus at three months earlier. There was nothing three months earlier, but there was a conjunction about a month before that date, on March 26, with the Sun, Venus, and the new Moon at inferior conjunction with Earth.

By April 27, 2500 cases were suspected among Mexico, USA, New Zealand, Canada, UK, Australia, and Spain, with 264 confirmed, and 152 deaths. The last were all in Mexico. Veracruz reported 1800 cases of flu-like symptoms by April 6; supposedly there were earlier cases since February (which may be unrelated). The earliest case dates to March 22. Mexico City reported "influenza like illnesses" as early as March 18, 2009.

Typically, the strain is clearly spread by human contact. The World Health Organization confirmed on April 24 that the H1N1 strain has "never been seen before." If this new H1N1 influenza strain is due to Venus, it represents an unusually short incubation period for a SARS type virus.

The alignment of superior and inferior conjunctions of March 26 (Mercury - Sun - Venus - Moon - Earth, with Mercury at superior conjunction), a month before the peaking of the 2009 Swine Flu outbreak on about March 24 is not unlike the alignment of planets on June 20, 1968 (Mars - Venus - Sun - Mercury - Earth), a month before the first outbreak of the H3N2 Hong Kong Flu of July 13, 1968. The Moon did not join this lineup until 5 days later, when Mercury had moved aside (Mars - Venus - Sun - Moon - Earth). The Hong Kong Flu reached maximum intensity two weeks after the first case of July 13, on July 27th.

Added Note, August 2011: Perhaps my suspicions about the Swine Flu were warranted. Andrew Bosworth, in "Exposed: The Swine Flu Hoax" (LewRockwell.com 2009), Joseph Mercola, in "Major Victory With Swine Flu Scandal" (LewRockwell.com 2009), and a number of other authors have pointed out that the 2009 Swine Flu is a hoax. As Mercola writes:

"It looks as though the swine flu pandemic of 2009 will go down as one of the biggest

government and pharmaceutical scams ever, renewing a healthy, and necessary, skepticism about the swine flu vaccine and the dubious dealings behind the implementation of worldwide mass-vaccination programs."

They could have asked me.

Recovering the Lost World, A Saturnian Cosmology -- Jno Cook

Appendix L: Long-Range Chronology.

\$Revision: 42.23 \$ (long.php)

Long-Range Chronology

For a brief listing of important dates see chapter 4.

The following is a list of climatic, cultural, and celestial events. Please see my note at the top of the Chronology chapter regarding astronomical notation and BC/AD notation, as well as the differences between Eastern Mediterranean "BC" dates and the calculated dates for China and Mesoamerica. Some of the dates from the "Annals of Shu" and the Palenque inscription from the Altars of the Cross, as shown below, are corrected. See the text for the reasons for this.

4.6 - 4.4 billion years ago

- Formation of iron meteorites.

ca 4.3 billion years ago

- Formation of the Moon.

ca 3.9 billion years ago

- Formation of the Earth.

ca 3.1 billion years ago

- Formation of Mars.

3.4, 3.1 billion years ago

- First prokaryotic cells

1.64, 1.2 billion years ago

- First eukaryotic cells

880 million years ago

- First multicellular forms

700 - 500 million years ago

- First instance of breakup of iron meteorites.

560 million years ago

- Cambrian "explosion" of life-forms.

300 - 100 million years ago

- Second instance of breakup of iron meteorites.

250 million years ago

- Permian extinction.

40 million years ago

- Earliest breakup of Chondrite meteorites.

3.2 million years ago

- Breakup of most Chondrite meteorites.

2.7 million years ago

- Breakup of SNC meteorites.

500,000 years ago

- Breakup of SNC meteorites.

414,000 ya

- Extent of Vostok Antarctic ice cores.

130,000 - 120,000 ya

- Eemian interglacial.

120,000 ya

- Lowest level of Greenland ice cores.

ca 40,000 - 10,000 ya

- Upper Paleolithic.

27,000 ya

- First Venus Figurines, then disappear for 12,000 years.

25,000 - 12,000 ya

- Last northern glaciation.

ca 15,000 - 10,000 ya

- Use of the cave of Lascaux. Some others date to 30,000 ya.
- Venus Figurines show up again.

ca 12,500 ya

- The end of last glaciation.

--== BC notation ==--

10,900 - 9,000 BC (12,800 - 11,500 ya, uncal C14)

- Destruction of North America (Firestone).
- Younger Dryas, extremely cold.
- The darkness before the chaos.

10,900 BC

- Start of the darkness before the chaos.
- Three ball plasmoids light up in the south.
- Start of the "first creation" of the Olmecs.

ca 11,000 BC

- First mixed farming and hunting in Levant.
- Cultivation of first grains in Anatolia.

9,600 BC

- A 200-year-long dry and cold period in Levant.
- Middle East abandoned.
- Farming moves to Black Sea from Anatolia.

9,500 BC

- Northern glaciation gone.

9,400 BC

- Weather improves, farming returns to Middle East.

9,000 BC

- Hypsithermal climatic period starts.
- Earth drops down from a lateral location near Saturn.
- End of Younger Dryas.

8,500 BC

- English Channel flooded.

ca 8,500 BC

- First use of tokens in northern Mesopotamia, Anatolia.

8,347 BC

- End of the "first creation" of the Olmecs.
- Prior appearance of "the turtle," Peratt column plasmoids.
- Prior appearance of the three hearth stones.

ca 8,000 BC

- Jericho walls and tower in Palestine (abandoned by 6,800 BC).
- Start of wet phase of Sahara.

ca 7,400 BC

- Catal Hiyuk in Anatolia (abandoned 6,200 BC).

ca 6,700 BC

- No more male figurines at Catal Hoyuk.

ca 6,500 BC

- Lepenski Vir graveyard along the Danube (to ca 5,500 BC).

6,200 BC

- A 400-year-long dry and cold period in Levant.
- Middle East abandoned; Catal Hoyuk abandoned.

ca 6,000 - 3,000 BC

- Neolithic Period.

5,800 BC

- Farming returns to Middle East.
- Warm, moist period starts.

ca 5,600 BC

- Black Sea floods, farmers disperse in every direction.
- Earth below Saturn.
- Approximate date of creation based on Septuagint bible.
- Early Ubaid period in Mesopotamia (to ca 4000 BC).

after 5,600 BC

- Figurines in Anatolia become abstract.

ca 5,400 BC

- Black Sea farmers have reached deep into Europe, Anatolia, Russia, Central Asian lakes region.

ca 5000 BC

- Wood henges appear in Central Europe.
- Carnac causeways constructed.

4939 BC

- Saturn starts to appear in the sky as an egg.
- Creation is dated from here by some people.

ca 4700 BC

- First Barrow graves in Portugal.

ca 4500 BC

- First barrow grave at Carnac.
- Pit graves (kurgans) in Eastern Europe (to 2000 BC).

ca 4400 BC

- Asian herders (nomads) show up in Eastern Europe.

4300 BC

- Birth of Thoth (from Turin Canon).

4077 BC

- Saturn lights up; "time" starts, creation.
- First descent of Mars.
- 8 Kings reign 1072 years by the *King List*.
- Birth of Adam (Saturn), 930 years before 3147 BC.

4004 BC

- Ussher, OT creation (1655 years to the flood of 2349).
- Approximate creation date from Mesoretic Bible sources.

ca 4000 BC

- Carnac "Grand Menhir" constructed.

3944 BC

- Creation date per Mesoretic Bible (1948 yrs, Adam to Abram).

ca 3800 - 3400 BC

- Barrow graves in France, Ireland, England.

3761 BC

- Creation date of the current Jewish calendar.

ca 3600 - 3400 BC

- Most European stone henges are started (West Kennet 3600 BC; Avebury since 3900 BC, the ditch in 3300 to 2630 BC).

ca 3400 - 2400 BC

- Passage graves in France, Ireland, England.

ca 3200 BC

- Other dates for New Grange 3200 BC, Avebury 3000 BC.

3147 BC

- Actual date of the end of the "Era of the Gods."
- Saturn removed; the "flood of Gilgamesh," the World Flood.
- The negotiations of the Gods start (to last 80 years).
- Warm moist period (from 5800 BC) ends.
- 200-year Jemdet Nasr period in Mesopotamia and Anatolia.
- Jupiter assumes a steep mountain shape.
- Year to 240 days.
- Sahara wet phase ends (circa 3440 BC).
- End of the "second creation" of the Olmecs.

3121 BC

- Birth of the Moon according to Palanque sculpture.

3114 BC

- Popular start of Maya calendar (actual is 3147 BC).

ca 3067 BC

- Most likely first regular appearance of Mars/Horus.

ca 3100 - 3000 BC

- Last Sumerian influences in Egypt.
- Construction of barrow graves falls off.

2896 BC

- Calculated creation date of the *Annals of Cuahitlan*.

ca 2860 BC

- Jupiter enters the asteroid belt; assumes the "shen" shape.
- End of the first Egyptian dynasty.
- Construction of the Sphinx at Giza.
- First possible use of shen for Olmec day names.

ca 2800 BC

- King 13 of Kish, Etana the shepherd, first historical king.

ca 2750 - 2700 BC

- Most likely the end of visits by Mars/Horus (2770 BC).
- Egyptian Old Kingdom third dynasty - to 2200 BC.
- Gilgamesh, dated King of Uruk, rebuilds walls of Uruk.

ca 2686 BC

- Step-pyramid of Zoser completed.

ca 2690 - 2550 BC

- Egyptian true pyramids at Meidum and Dashur completed.

2630 BC

- Last of the Horus Kings in Egypt.

2627 BC

- Pyramids started in the Andes.

ca 2527 BC

- Jupiter resumes a mountain shape.

ca 2590 - 2500 BC

- Giza pyramids in Egypt completed.

2490 BC

- Silbury Hill built in England (2490 - 2340 BC).

ca 2438 BC

- Jupiter loses its mountain-shaped coma (estimated).

ca 2400 BC

- Stonehenge is reconstructed, east causeway added.

2349 BC, September 8

- Disturbance by Venus, September 8 (Olmecs)
- Noachian flood (fall of the Absu).
- Old Kingdom reduces agriculture and construction.
- Dating of flood legend in China.
- Stonehenge reconstruction stops.
- Year to 260 days.
- Jupiter again develops a mountain-shaped coma.
- Tzolkin 260 day calendar introduced.
- The red snake in the sky appears, the Uroboros.

ca 2347 BC or after

- First records of the *Annals of Shu*.

2345 BC

- *Pyramid Texts* first mention Osiris.

ca 2338 BC and after

- Sumer conquered by Sargon of Akkad.

2336.8 BC (corrected)

- "Birth" of Jupiter, Venus, Mars: inscriptions at Palenque.

ca 2300 - 2200 BC

- First transcribed records of the *King List*.

2282.6 BC (corrected)

- Moon in orbit ("crowns herself"), Palenque, recorded as 2305.

2277 BC (corrected)

- Annals of Shu: Moon joins Yao, listed as 2287 BC.

2247 BC

- "Tower of Babel," dated by Ussher as "after 2247 BC."

2205 BC

- Shun (the Moon) retires or "dies," *Annals of Shu*.
- Yu, first king of the Xia Dynasty.

2193 BC (156 years after the fall of the Absu)

- A third disturbance by Venus.
- Severe climatic downturn.
- 200 years of drought worldwide.
- Fall of Akkad, end of Old Kingdom.
- Malta depopulated.
- Year goes to 273 days.
- Fire on the Moon.

2192 BC

- Atland sinks, according to the *Oera Linda*.

2150 BC

- Yao (Jupiter) dies, listed as 2257 BC.
- *Chilam Balam*: "fire on high" (katun 2167 - 2147 BC).
- 2155 BC: *Annals of Shu*: Celestial Phenomena.
- ca 2150: Cylinder of Gudea: splendor of Ningirsu.
- 2150 BC: extent of Abraham's lifetime, 175 years.
- likely date for Ussher's "Tower of Babel."

ca 2100 BC

- Stonehenge completed after a 200-year delay.

2052 BC

- Start of Egyptian Middle Kingdom.

ca 2000 BC

- Composition of the *Enuma Elish* creation myth.

1996 BC

- Abram born, Bible record (350 years after the OT flood).

1936 BC

- Second return of Mars, 1130 years after 3067.
- Destruction of Sodom and Gomorrah.

1887 BC

- Monte Alto founded, Guatemala.

ca 1750 BC

- *Code of Hammurabi*, standard corrected chronology.

1492 BC, April 19

- Disturbances of Earth by Venus, April 19 (Olmec).
- Exodus of Moses.
- Abrupt end of the Middle Kingdom.
- Chinese Xia dynasty suddenly ends.
- Twenty years of dense cloud cover.
- Year to 360 days.
- Start of the Haab calendar,

ca 1500 - 1200 BC

- Indo-European Hittites settle in central Anatolia.

1440 BC

- Destruction in Mesoamerica.
- (1442 BC) The sun stands still for Joshua.

1367 BC

- Monte Alto abandoned.
- San Lorenzo established.

ca 1350 BC

- Santorini explosion, one of a number of possible dates.
- Founding of the Poverty Point, LA, concentric berms.

ca 1200 BC

- Battle of Troy as claimed by Herodotus.

1125 BC

- The Shang Dynasty ends.

ca 1100 BC

- Fractional math based on the Eye of Ra is in use.

1027 - 221 BC

- Chou Dynasty.

900 BC

- The Ark is moved to the temple in Jerusalem.

847 BC

- San Lorenzo destroyed.
- Tres Zapotes established.

806 BC

- Third round of appearance by Mars near Earth (9 times to 687 BC).

Julian - Gregorian event

806 BC - Spring 805 BC

791 - Oct

777 - Feb 776 BC? -- the 'ballgame?'

762 - Oct -- lesser impact

748 - Feb 28 747 -- Earth shock, year changes

733 - Oct -- lesser impact

718 - Mar

703 - Oct 702 -- lesser impact

688 - Mar 687 -- last sight of Mars

776 BC

- Venus, Mars, and Mercury ballgame.
- Visit of One-Hunahpu and Seven-Hunahpu to the underworld.

772 BC

- First Olympic Games.

762 BC

- Alternate visit of One-Hunahpu and Seven-Hunahpu to the underworld.

before 747 BC

- La Venta takes the "may."

747 BC, February 27

- Mars jars Earth, changes the Earth orbit, February 26.
- Nabonassar introduces a new chronology, effective February 27.
- Olmecs set Long Count to 6.0.0.0.0, February 28.
- Calendar reforms follow worldwide (Rome February 28).
- Founding of Rome (there are other dates).
- Four more close calls by Mars over next 60 years (Olmec).

- (before 747 BC) Rome adds two months to the calendar.
- Haab modified with 5 additional days.

ca 750 BC

- Hesiod and Homer write (traditional).

689 BC

- Destruction of the temple of Marduk at Babylon.

686 BC, March 23

- March 23: Mercury jars Earth. Mercury on fire.
- Sennacherib's army disaster.

685 BC, June 15 to July 25

- Temple of Marduk rebuilt at Babylon.
- Venus and Mercury start to blaze, June 15.
- Jupiter develops a coma, July 9.
- Jupiter releases a plasmoid bolt, July 14.
- Jupiter's plasmoids lands at the Sun, July 25.

684 BC (astronomical)

- Earth's perihelion changes, polar axis relocated in space.
- A new Great Year started on March 8th (old equinox).

670 BC

- Earth's orbit suddenly becomes circular.

628 - 551 BC

- Zarathustra, Zoroastrianism (Mazdaism).

612 BC

- Library of Assurbanipal at Nineveh burns down.

607 BC

- Calendar revised, Monte Alban.

604 - 531 BC

- Lao-tse (China), Taoism.

597 BC

- Jews exiled to Babylon.

563 - 483 BC

- Siddhartha Gautama, the Buddha (India).

536 BC

- Cyrus allows the Jews to return to Jerusalem.
- Jewish world history compiled, Bible edited.

551 - 479 BC

- Confucius (China).
- *Annals of Shu* collated by Confucius.

430 - 404 BC

- Peloponnesian Wars.

334 BC

- La Venta destroyed.
- Monte Alban primacy.

ca 331 BC

- Alexander receives celestial records from the Chaldeans.

332 BC

- Death of Alexander.

ca 280 BC

- *King List* published by Berossus in Greece.

275 BC

- Monte Alban rebuilt.

272 BC

- Mithraism in Parthia.

239 BC

- *Canopus Decree* attempts calendar reform.

213 BC

- Book burning in China.

128 BC

- Hipparchus calculates the precession of the equinox.

ca 100 BC

- Josephus claims the electric fire stopped.

AD 179

- Teotihuacan established.

ca AD 600 - 800

- Last red ring of the Absu (the Uoroboros) fades.

ca AD 700

- Monte Alban in decline.

AD 692

- Teotihuacan destroyed.

ca AD 726

- Tula established.

ca AD 900

- Last of the Uoroboros disappeared.

ca AD 1170

- Tula abandoned early.

ca AD 1219

- The "may" at Cholula.

ca AD 1600

- Last of the falling Absu sprinkles.

ca AD 1840

- Last of the path of the ecliptic faded.
-

Recovering the Lost World, A Saturnian Cosmology -- Jno Cook

Appendix M: The Red Sirius.

\$Revision: 42.7 \$ (sir.php)

Contents of this Appendix: [\[Ptolemy\]](#) [\[Sima Qian and Yu Ji-cai\]](#) [\[Gregory of Tours\]](#) [\[Al-Sufi\]](#)
[\[The Maya\]](#) [\[Summary\]](#)

Ptolemy, AD 200

In the second century AD, Ptolemy (working from Alexandria in northern Egypt) reports the star Sirius as red, as do others in late antiquity. However, Sirius is listed as white by the Arab (Persian) astronomer Al-Sufi in the *Book of fixed Stars*, published in AD 964. Both Ptolemy and Al-Sufi were very competent astronomers.

At a much earlier time Sirius was clearly recognized as white. As the brightest star in the sky, ancient records appropriately speak of Sirius as "the star of Venus," where Venus was the brightest planet in the sky. This would not make much sense if Sirius were inherently red.

Before 685 BC, as developed in the text, Sirius was located only a few degrees below the equatorial, rising almost directly east and setting almost directly west. It would have traveled above the Absu, which nowhere reached the height of the equatorial in the south skies. For example, at Cairo, at **30 degrees** latitude (0.13 degrees south of Alexandria), Sirius would reach its highest point in the south sky at an elevation of about **61 degrees** before 685 BC.

My estimate of the limit of the intact Absu was 8500 miles (14,000 km) above the surface of the Earth at the equator. This was seen at about **48 degrees** above the south horizon at Cairo. At this time Sirius would have been white, since it did not shine through the Absu or the remaining red ring after the fall of the Absu.

In 685 BC the location of the equatorial shifted, so that at Cairo Sirius was lowered to **43 degrees** at its highest point in the south sky. It now rose in the southeast, and set in the southwest. Sirius was now reported as "red," which means it appeared behind the last remnant ring of the Absu. From this information at Cairo we can locate the last red ring.

[Image: Sight line to red ring. Illustration by J. Cook.]

The elevation of the red ring above the equator of the Earth can be found from the relationship:

$$a / \sin(A) = b / \sin(B) = c / \sin(C).$$

From the diagram above, the location of the ring above the Earth's equator can be found from the radius of Earth and the two adjacent angles, where angle **A** is the latitude of Cairo, angle **C** is between the sight line and the extension of a radius line at the equator.

A = 30 degrees, the latitude of Giza

B = 90 + 43 = 133 degrees

C = 180 - B - A = 180 - (90 + 43) - 30 = 17 degrees.

In the following, **b** is the height of the ring from the center of the Earth and **c** is the radius of the Earth. Thus:

$$b = c * (\sin(C) / \sin(B)),$$

$$b = 4000 * (\sin(133) / \sin(17)) = 10,005 \text{ miles.}$$

The last red ring is thus located **10,005 - 4000 = 6,000 miles** (9,600 km) above the equator.

Ptolemy, I should note, actually could have had it both ways. For although Sirius would have been seen as red when it stood high in the sky, it rose in the southeast, away from the red snake in the sky (which touched the eastern horizon directly east), and set in the southwest, also away from the red ring. At these two locations it would have been white.

But in rising higher in the sky Sirius crossed the remaining red ring. In fact, at the latitude of

Cairo I would presume that Sirius spent most of its travels behind the red ring.

Sima Qian and Yu Ji-cai, AD 100 and 200

The change of color also shows up in Chinese documents, as, for example, in the *Book of Asterisms* by Sima Qian, dating from about 100 BC, which reads:

"If Wolf [Sirius] shows horns or changes colour, then there will be much banditry,"

or, from *Secret Garden of the Observatory* by Yu Ji-cai, of circa AD 200:

"If the Wolf Star shows rays or horns, or shakes about, or changes colour, then there will be war."

This information is from Jiang Xiao-yuan, in "The colour of Sirius as recorded in ancient Chinese texts" (*Chinese Astronomy and Astrophysics*, 1993), which sets out to prove that Sirius is noted as being white in four records, each dealing with color standards for stars, dated between 100 BC and AD 650, which were judged by Jiang to be more reliable than the astrological texts quoted above. Jiang admits, however,

"Although ancient Chinese writings always had a tradition of copying what previous authors had said, so that the four items listed [in the article] are probably correlated to some degree, we should not therefore deny ancient Chinese astrologers of any originality whatever. That [the "Jinzhou Book of Prognostication" of circa AD 100] lists both Sirius and Vega as standards for white star is worth noting. These two are indeed white bright stars of the same type."

However, the "shaking," "horns," and "changes in color" would be explained if Sirius, the brightest star in the sky, traveled behind a portion of the last remaining ring -- "shaking" being caused by the passage of the moving ring in front of the star (like with Saturn, the Earth's equatorial rings move at rotational speeds different from the planet). The "horns" are caused by refraction by the striation pattern of the intervening ring (the rings of the Absu had been described as reeds growing in a swamp and as bushes, thus radially oriented), and a "color change" is caused by entry and exit of Sirius from behind the ring.

This last is caused, as noted above, by the fact that Sirius is "attached" to the dome of the stars and thus travels in a circle with the polar axis as its center, whereas the rings are an artifact of the Earth, forming a crescent shape in the sky which is gathered together at the east and west cardinal location and spreads apart at its highest point in the south skies.

A look at where Sirius and the red ring were located in the sky when seen from Beijing might help. Beijing is at **39.5 degrees** north latitude. Thus the equatorial rose **50.5 degrees** up from the south horizon. With Sirius placed at a declination of **16.3 degrees** (circa AD 150), it rose to a maximum height of **34.2 degrees**.

As before, the length of the sight line is:

$$a = \sqrt{10000^2 + 4000^2 - 2 * 10000 * 4000 * \cos(39.5)}.$$

This is **7367 miles**. From this the angle of elevation to the rings can be found as:

$$\sin(C) = (4000 / 7367) * \sin(39.5) = 0.345.$$

From sine tables this is equal to an angle of **20.2 degrees**. The elevation is thus **180 - 39.5 - 20.2 - 90 = 30.3 degrees**. This is **3.9 degrees** below the highest location of Sirius in the south sky. Thus Sirius moved across the red ring twice each night.

Gregory of Tours, AD 550

In about AD 560-590, Gregory of Tours still calls Sirius "reddish," although he may have copied that information from Ptolemy. Tours is at **47.38 degrees** north latitude. At Tours the equatorial would be seen at an elevation of 90 degrees less the latitude, **90 - 47.38 = 42.6 degrees**. In AD 550 Sirius would be seen at an angle of about **16 degrees** below the equatorial (this is true everywhere for this date and for the early part of the first millennium AD), thus at **26.6 degrees**.

Using the same geometry as before, we can find the distance between the observer and the intersection of the equatorial at the location of the remaining ring from:

$$a = \sqrt{b^2 + c^2 - 2 * b * c * \cos(A)}$$
$$a = \sqrt{10000^2 + 4000^2 - 2 * 10000 * 4000 * \cos(47.38)}.$$

This is **7863 miles**. The angle C can be found from:

$$\sin(C) = (c / a) * \sin(A)$$
$$\sin(C) = (4000 / 7863) * \sin(47.38) = 0.3743.$$

The corresponding angle (from sine tables) is **22 degrees**. Subtracting this angle and the latitude from **180 degrees** yields **110.6 degrees**. Now subtracting **90 degrees** (the angle between the Earth radius and the horizontal), determines that the red ring would have been seen at an elevation of **20.6 degrees**.

This is a considerable span -- **4.6 degrees** -- below the culmination of Sirius. The path of Sirius would thus cross the red ring, and Sirius would turn red twice a night.

Al-Sufi, AD 900

When, after about AD 900, the Arab astronomer Al-Sufi catalogues stars, he lists Sirius as

"white," as it still is today. Al-Sufi worked from Isfahan at **33.63 degrees** north latitude. At Isfahan the elevation of the equatorial is at **56.4 degrees**, and Sirius travels (at about AD 900) at **15.4 degrees** below the equatorial, and thus culminates at an elevation of **41 degrees** above the south horizon.

Using the same geometry as above, the distance from the observer to the location of the ring (assuming it existed still) at the plane of the equatorial can be found from:

$$a = \text{sqrt}(10000^2 + 4000^2 - 2 * 10000 * 4000 * \cos(33.6)).$$

This is **7026 miles**. From this the angle of elevation to the rings can be found as:

$$\sin(C) = (4000 / 7026) * \sin(33.6) = 0.315.$$

This represents an angle of **18.3 degrees**. The elevation is thus **180 - 33.6 - 18.3 - 90 = 38.1 degrees**. This is only **2.9 degrees** below the culmination of Sirius in the south sky. It suggests that, although at this location Sirius would have crossed the red ring if it still existed, by AD 900 the ring probably had disappeared. This is also suggested from the Maya construction project in AD 800. On the other hand, as an astronomer, perhaps Al-Sufi realized that the white star Sirius just passed through the red ring twice each day.

Maya, AD 800

After about AD 800, when the Maya start the construction of a 61-mile (98 km) causeway running from east to west across the Northern Yucatan, this last red ring had most likely disappeared. It may, in fact, have been gone before AD 600. In the 20th century AD, the Maya still recalled the "cord in the sky," through which blood flowed, but which had disappeared in the past. The 16th-century AD *Popol Vuh* calls it the "river of blood." It can be assumed that the "river of blood" was like the "river of pus" (the ecliptic, as in the *Popol Vuh*) and that the "river" probably did not subtend more than a few degrees in the sky.

An investigation by George Jones in about AD 1910 at Quito, Peru, determined a width of the ecliptic as **2 to 3 degrees**. The earliest iconography of the Olmecs at La Venta, dating to around 600 BC, also show the "Saint Andrew's Cross," the crossing of the ecliptic and equatorial in the night skies at the time of the equinoxes, as two bands of nearly the same width.

Summary

Let me summarize the data, presented mostly in historical order, and adding Rome (AD 200) and Beijing (AD 150).

Intersection of Sirius with the red ring							
location	era	latitude	equatorial	Sirius declination	Sirius elevation	ring elevation	diff
Cairo	200	30.0 deg	60.0 deg	16.3 deg	43.0 deg	43.0 deg	0.0 deg
Beijing	150	39.5	50.5	16.3	34.2	30.3	3.9
Rome	200	41.9	48.1	16.5	31.6	27.3	4.3
Tours	570	47.4	42.6	16	26.6	22.0	4.6
Isfahan*	950	33.6	56.4	15.4	41.0	(38.1)	2.9

*-- Sirius listed as white at this time

Declination of Sirius depends on the date

Since 685 BC, the path of Sirius through the sky always starts and ends about **19 degrees** south of directly east and west. Thus the semi-circle described by the path of Sirius could fall completely within the semi-circle of the rings, but would cut through the band of the red ring and perhaps rise above it when directly in the south. Only at Cairo does the upper portion of the path of Sirius coincide with the ring -- but that is how I have defined this condition.

It is, of course, arbitrary, but justified in that many other authors from late antiquity note the redness of Sirius, including Babylonian cuneiform tablets after about 650 BC (at 33.3 degrees latitude) and Roman authors (at 41.9 degrees north latitude). The results for Rome in about AD 200 are much the same as for Beijing at the same date. I have added Rome to the list above.

Since Rome is at 41.9 degrees latitude, it could be suggested that the red band in the sky in circa AD 200 extended across 4 degrees in the sky. Four degrees is the equivalent of two hand-spans (without the thumbs) at arm's length. This measure might also be suggested by two other data points. First, the records of planetary actions in Babylon after 650 BC seem to indicate rather sudden changes in refractive patterns, suggesting a tight band of red. Second, the Quiche *Popol Vuh* call the red band a "river." The details of that story are contemporaneous with the plasma event of 685 BC.

I would expect Al-Sufi at Isfahan (33.6 latitude) to have seen a red-colored Sirius, for the latitude of Isfahan falls between Cairo and Rome, except that the date is obviously late. A hundred years earlier the Yucatan Maya were rebuilding the red road in the sky on Earth -- which almost guarantees that the red ring had disappeared within the previous hundred years or so.

In Beijing (39.5 degrees latitude), Sirius could have been the measure for white, for it is very bright, but could also legitimately described as changing color -- since it would have traveled behind the red ring in reaching its culmination. This is, in fact, true for all the sites listed above.

Calculations are in Unix bc notation, where ^ denotes exponentiation; the functions a(rctangent), s(ine), and c(osine) use radians; angle conversions to radians or degrees by the divisors rad=.017+ and deg=57.2+; other functions are shown as f(); tan()=s()/c()

Recovering the Lost World, A Saturnian Cosmology -- Jno Cook

Appendix N: Age of the Universe.

\$Revision: 42.11 \$ (age.php)

Contents of this Appendix: [\[The Milky Way\]](#) [\[The Local Group\]](#) [\[The Virgo Supercluster\]](#)
[\[The Visible Universe\]](#) [\[Endnotes\]](#)

The Age of the Universe

The accepted age of the Universe is a modest 15 billion years, based on a "Big Bang" event at the beginning of time. I won't bring forward the accumulated data which argues against the "Big Bang" -- a derisive term coined by Fred Hoyle, which stuck.

The Milky Way

It would be better to take a look at Halton Arp's book *Seeing Red* (1998). Our galaxy is the daughter of a nearby galaxy in Virgo, and we in turn seem to be the mother and grandmother of two additional generations of offspring galaxies. I have seen recent estimates that it would take 100 billion years to "form" a galaxy. But Arp suggests (through an example) as little as 8 billion years. I'll use the very conservative value of 8 billion years between generations. As a grandmother, the Milky Way is three generations old.

Age of the Milky Way galaxy

3 times 8 = 24 billion years.

If the Milky Way is typical of a leaf on the branches of the Universe, then the Universe might be very old. If we could count galaxies (they count in the billions), and get some idea of the connections between them (they tend to form in groups), we could form an estimate. If there are indeed billions of galaxies, and they multiply by sending new pairs out from their center (as Arp has suggested) every 8 billion years, then the galaxies have multiplied like rabbits. I'll do the math for a Fibonacci series. [\[note 1\]](#)

The Local Group

The local group, to which the Milky Way belongs, contains only about 40 galaxies. The 9th term of the Fibonacci series reaches a value of 34. That represents 9 generations, assuming that *this* portion of the Universe started from a single other galaxy.

Age of the Local Group of galaxies

9 times 8 = 72 billion years.

The Virgo Supercluster

But we are part of the Virgo Supercluster which contains about 27,500 galaxies. The 23rd term of the Fibonacci series reaches a value of 28,657, representing 23 generations.

Age of the Virgo Supercluster

23 times 8 = 184 billion years.

The Visible Universe

A web source lists 3,850 billion galaxies in the "visible" Universe. The 62nd Fibonacci term is 4,054 billion.

Age of the Visible Universe

62 times 8 = 496 billion years.

The really big numbers generated by a Fibonacci Series increase much faster than the index of the series. It is the "index" which is a measure of age. Thus there might be a finite number which represents the real age of the Universe. However, there are plenty of people who believe the Universe is infinite in size and infinite in age. [\[note 2\]](#)

Endnotes

Note 1 --

The estimates on the galaxies at various visual spacings from Earth are from Richard Powell, [\[www.atlasoftheuniverse.com\]](http://www.atlasoftheuniverse.com).

For an expansion of Fibonacci terms see [\[www.maths.surrey.ac.uk/hosted-sites/R.Knott/Fibonacci/fib.html\]](http://www.maths.surrey.ac.uk/hosted-sites/R.Knott/Fibonacci/fib.html)
[\[return to text\]](#)

Note 2 --

Lars Wåhlin, in *The Deadbeat Universe* (1997, rev. 2003), estimates that one fourth of the

life of a collapsing universe has passed, which will end at the count of $2.47 * 10^{20}$ seconds. One fourth of this is equal to $1.95 * 10^{12}$ years -- 1,950 billion years. That is about 4 times the value I derived.

Dewey Larson, in *The Structure of the Physical Universe* (1959), suggests that the Universe is not infinite in size, but only in time, and suggests a replenishment from a parallel time-based Universe.

Recovering the Lost World, A Saturnian Cosmology -- Jno Cook

Appendix O: List of Books.

\$Revision: 42.40 \$ (books.php)

A List of Books

Most often bibliographies weigh in as a cudgel to convince the reader of the level of scholarship of the author. And most often they are only accessed by the reader to check if a favorite author has been included for consideration. In fact, I left off the list any number of books -- books I totally disagree with, or which have served me badly despite some measure of inspiration. I should not subject you to trash and junk.

Annotated bibliographies, as you will find here, are much more interesting. They present the author as if he is pushing a pile of books across the table toward the reader, saying, "read these first," noting their individual importance, what was learned from them, and also what was glossed over or neglected. Ideally such a source list ought to be organized by the chapters of the prime text, but I only do that in the second half of this list. In the first half I will list books by topics. Some 400 or 500 books have been accessed, of which about half are in my possession. In addition I have accessed about 4600 other source documents from the Internet, disappeared websites, specialized CDROM's, most all of which are to be found in the "files" subdirectory.

Some books have by this time (2010) appeared on the Internet, making them suddenly amenable to instant textual searches. I'm not listing math, physics, chemistry, etc., required to get an engineering degree, or most of history, literature, art, astronomy, and other topics needed to round one out beyond engineering. Thus missing also are Hesiod, Homer, Herodotus, Thucydides, Ovid, and any number of other Greek or Roman commentators.

What Else Is Missing Here

Except for (I think) three references to texts on plasma, all texts dealing with course work for an engineering degree are missing: Analytic Geometry, Differential Calculus, Integral Calculus, Differential Equations, Statistics, Investment Discounting, Set Theory, Boolean Algebra. That is the math. Then there are the courses in Physics, Chemistry, Materials, Mechanics, and the usual Thermodynamics. Some additional topics particular to my degrees in Electrical Engineering and Industrial Engineering: Field Theory, Transmission Lines, Fourier Analysis, Information Theory, Difference Calculus, Operations Research. I should note also Particle Physics (Atomic Physics), which we called the Atom Bomb Course.

I actually learned Boolean on my own, and used it for the design of relay switching circuits for years. Similarly I learned just enough spherical geometry to be able to apply it for a computer program which calculated the location and time of the rising Sun along with the zenithal angle for any day and latitude ([\[sun.html\]](#) available locally).

[Image: Books to read. After Hannah Warren.]

Do I remember any of this? No. But I know the basics of *what* exists, where to look it up, how to get into the topic again. This is the result of the discipline of engineering rather than any specific course work: you learn that there are likely solutions, and you learn to research them.

At some point, I think as part of the Industrial Engineering course work, I learned a variety of Basic, which was just being introduced at that time for use on a University mainframe, with input via punched cards. Where I worked at the time I had to backtrack and use punched cards as program and data on hardwired "accounting machines" to carry out a simulation of transit travel demand. But the outfit got a mainframe a year later, and Fortran 4 was offered

by the supplier, General Electric, still using punched card as input. Since that time I have learned portions of a number of languages -- including shell programming (Bash), Perl, PHP, sed (yes!), and any number of other odds and ends, but all to the point of solving some problem, or the need to design a script. And then I quickly forget.

Primary Source Books

Immanuel Velikovsky, *Worlds in Collision* (1950)

The book which started it all, relating the near contact between Earth and Venus at the time of the Exodus of Moses. Almost entirely evidenced from tales and histories rather than physical data.

Immanuel Velikovsky, *Earth in Upheaval* (1955)

A compendium of physical catastrophic evidence. Most of it has been more clearly defined since 1955.

Immanuel Velikovsky, *Ages in Chaos* (1952)

The first of a series of book presented as a revision of Middle East chronology. Followed by *Peoples of the Sea* (1977); *Rameses II and His Time* (1978); and, never published: *The Dark Ages of Greece* and *The Assyrian Conquest*. This data is mostly accepted, although still under discussion. The unpublished titles are on line at [\[www.varchive.org\]](http://www.varchive.org), which is Jan Sammer's website..

Giorgio de Santillana, and H. von Dechend, *Hamlet's Mill* (1969)

The forerunner to the post-Velikovsky polar configuration thesis by David Talbott (below), dealing mainly with the fall of the Saturnian polar configuration. Scholarly, but offers no physical model, except to suggest a succession of "ages" based on an erroneous backward extension of the precession of the equinox. The amount of information presented, however, is astounding. Originally undertaken as an antidote to Velikovsky's book.

Julian Jaynes, *The Origin of Consciousness in the Breakdown of the Bicameral Mind* (1976)

Worth reading a few times. The specific conclusions may not be acceptable to you, but the information about how we think is absolutely solid. Jaynes claims that the *subjective consciousness* we exhibit did not become part of human culture until the first millennium BC -- late, very late. Most interesting is his assembly of cultural evidence from the second and first millennium BC, most of which is related to the gods of Mesopotamia and Greece, but unrelated to the literature of catastrophism. This has been one of my most solid sources.

Henry Bauer, *Beyond Velikovsky: The History of a Public Controversy* (1984)

Looks like a "must-have" text of reasonable criticism of Velikovsky's thesis in being a

summary, but turns out to be very mainstream and biased.

David Talbott, *The Saturn Myth* (1980)

The book which started all the interest in the polar imagery. This was the answer to what de Santillana and von Dechend were looking for. Talbott's search among Egyptian and Mesopotamian sources established the image of a large globe above the Earth at the North horizon in remote antiquity. Many other researchers have followed up on his initial concepts, proposing various physical models. The original purpose was to disprove Velikovsky.

Alfred de Grazia's writings.

Everything is on line at [\[www.grazian-archive.com\]](http://www.grazian-archive.com) in PDF as complete books or HTML as separate chapters.

-- ***Chaos and Creation*** (1981) more or less (more less than more) parallels these pages, except that it is a Young Earth thesis, and simply lacks any consideration of the information which has been developed in the last two decades.

-- ***God's Fire*** (1983) is the story of Moses and the Exodus (1500 BC). De Grazia reviews works by every biographer of Moses since antiquity, the operation of the Ark, the organization of the camps, the details of the whole migration, the electrical tricks of Moses, his interaction with Yahweh, and the character and psychology of Moses.

-- ***The Velikovsky Affair*** (original 1966, current 1978) records the tribulations of Velikovsky on the publication of *Worlds in Collision*. With essays by Ralph Juergens, Livio C. Stecchini, and Velikovsky. The two introductions by de Grazia are the best overviews to all of the controversy.

-- ***Cosmic Heretics*** (1984) is an amazing biography of the whole alternative cosmology movement since Velikovsky. Perhaps too verbose and too much about Alfred.

-- ***The Disastrous Love Affair Of Moon And Mars*** (1984); an absolutely great analysis of the Mars and Venus incident in the *Odyssey*, which was left out of the *Iliad*.

-- ***The Iron Age of Mars*** (2009), a compendium of the history of catastrophes of the 8th and 7th century BC. The most noteworthy resource for that era.

David Talbott and Wallace Thornhill, *Thunderbolts of the Gods* (2005)

A first book which will tie together Saturnian and plasma information. A general introduction to the background of mythology which is the primary pointer to the events of antiquity.

-- ***The Electric Universe*** (2007)

An excellent introduction to plasma and the electricity of space, the sun, comets, and

planets.

Donald Scott, *The Electric Sky* (2006)

An explanation of the electrical theory of the Sun. As an electrical engineer and astronomer, Scott knows what he is talking about, and provides a clear and readable text, also covering stars and galaxies.

Dwardu Cardona, *God Star* (2006)

Cardona here traces Gods and initial conditions of the Earth as recalled from the earliest mythological sources. He adds a vast collection of biological and geological data to support his claims for a Saturnian polar sun. Additionally, Cardona recounts the theories which have come forward in efforts to explain the Saturnian polar globe over the last 25 years, as well as attempts to account for biological and geological discrepancies.

Three additional books have followed: *Flare Star* (2007), *Primordial Star* (2009), and *Metamorphic Star* (2011), which continue to maintain the original thesis and expand on it.

Some Background Books

There are a hundred others, but I had to start somewhere. The following list mostly covers meta-topics -- in archaeology, astronomy, paleontology, geology, biology, history, etc. Topics like electrical engineering, field theory, statistics, atomic physics, and the associated math, are not covered, for they were part of my education. I read all the time.

C.J. Ransom, *The Age of Velikovsky* (1976)

Ransom actually has a Ph.D. in Plasma physics, so that not only does he know what he is talking about, but he has the mindset of an engineer in being able to separate facts from pretense. The book covers the standard accepted theories as presented by Velikovsky, carries through with the expansion by others through the 1970s, and includes the AAAS meeting of 1974 which convicted Velikovsky of scientific heresy.

Robert Bakker, *The Dinosaur Heresies* (1986)

A wonderful book; Bakker knows how to conduct research in his field. His claim is that dinosaurs were warm-blooded. He mostly dismisses the meteorite impact theory for the dinosaur extinction, and adds a few lines about the changes circa 65 million years ago which will leave you gasping.

Halton Arp, *Seeing Red* (1998)

Another researcher who knows what he is doing, Arp produces evidence of the bipolar creation of adjacent galaxies from parent galaxies. The red-shift/distance relationship is shown to be a fallacy.

Sylvanus Morley, *An introduction to the Study of Maya Hieroglyphs* (1915)

A far ranging and detailed investigation into the Maya calendar system and the glyphs involved in this. However, Morley uses the 'Morley-Spinden' correlation, which is off by three years from the use by others .

Diego de Landa, *Account of the Affairs of Yucatan* (1975 translation by A. R. Pagdan)

A comprehensive overview of the Yucatan Maya customs and beliefs. Original (not extant) consist of AD 1566 notes in Spanish, translated to French in 1864 by de Bourbourg from abstracts. This is the only contemporaneous accounts of the Maya from the 16th century.

Jared Diamond, *Guns, Germs, and Steel* (1999)

The absolute exhaustive source on the spread of agriculture, animal domestication, and languages during the Neolithic. Answers many of the questions on how and why cultures spread. See also his *Collapse* (2005) which deals with ecological issues -- very insightful and extendable to the past.

William Howells, *Back of History* (1954, 1963)

Paleolithic and Neolithic studies. The first chapter, a thorough explication of climatic conditions, is worth the price of the book alone. Wish there were an update.

Gordon Taylor, *The Great Evolutionary Mystery* (1986)

Manages to dismiss just about everything about Darwinian evolutionary theory. Historical account of controversies. Read Bakker for a differing perspective on some items.

Richard Dawkins, *The Blind Watchmaker* (1986, 1996)

A popular presentation of the case for Darwinian evolutionary theory, in contrast to the above. But arguments are too frequently from mechanical analogs.

Derek Ager, *The Nature of the Stratigraphical Record* (1973)

Questions the nature of stratigraphic dating techniques. A thick book. In *The New Catastrophism* (1993) Ager violently disputes Velikovsky's use of stratigraphic evidence. Han Kloosterman, a Dutch geologist, wrote in 1976, "It occurred to me as singularly insignificant, somewhat like a treatise on the danger of knitting-needles written during a world war." Kloosterman is one of the *et alii* of the Firestone paper of 2007.

Ian Tattersall, *The Fossil Trail* (1995)

Describes the paleontology of hominid fossils from the perspective of an insider. He has coauthored articles with Niles Eldredge (who developed the concept of 'punctuated equilibrium' with Stephen Gould). Especially interesting are the details of how the researchers remained stuck with received wisdom, and only slowly adopt new concepts.

James Shreeve, *The Neanderthal Enigma* (1995)

About the European and Middle Eastern Neanderthal fossils, by a science reporter. As a science reporter, this book is eminently readable, but as inconclusive as Tattersall's. Nothing really is resolved, yet all the data is presented, generally from discussions with the researchers at the source sites. Only in the last two chapters does he attempt a resolution, but it is entirely based on applying a contemporary perspective to the remote past.

William Ryan and Walter Pitman, *Noah's Flood* (1998)

Describes the evidence bearing on the sudden flooding of the Black Sea through the Bosphorus in circa 5600 BC, and the diaspora of the mixed-farming peoples (and languages) to Europe, Asia Minor, Mesopotamia, and central Asia (the last to return on horseback a thousand years later as the speakers of Indo-European languages). Twenty years of research by them and many others.

Richard Rudgley, *The Lost Civilizations of the Stone Age* (1999)

Neolithic cultures comprehensively detailed with respect to languages, writing, medical practices, religious symbolism. A very good source which should stand your ideas of "advances" on its head.

Denise Schmandt-Besserat, *Before Writing: From Counting to Cuneiform* (1992)

Use of tokens for record keeping since 8000 BC, leading to cuneiform by 3100 BC. Amazing. But also see Gimbutas, below, for clear indications of some sort of script in the Balkans and Minoan Crete earlier.

Marija Gimbutas, *The Civilization of the Goddess* (1991)

Neolithic worship of the Fat Lady in the sky. European Neolithic communities, 7000 to 3500 BC. Concentrates mostly on the Balkans, Greece, and Anatolia, with imagery which carries through from Paleolithic times to the Iron Age. See also ***The Goddesses and Gods of Old Europe* (1982)** - with 250 illustrations. There are additional titles. Gimbutas reads a dozen European languages, and thus outdoes any other researchers in terms of an overview. Her last book is ***The Living Goddess* (1999)**, published posthumously.

Nicholas Osler, *Empires of the Word* (2005)

Authoritative, detailed history of human languages in their cultural settings. Very interestingly, he details why some languages last, some disappear.

James Mellaart, *Catal Hoyuk* (Çatal Höyük) (1967)

A Neolithic city in Anatolia, with preserved murals and sculptures, a village of mixed farming and hunting people, lasting a thousand years to 6000 BC. Interesting for its bizarre symbolism, but the book probably overstates the case.

Noel T. Boaz, *Eco Homo* (1997)

Human evolution in context of ecological and environmental changes over the last 8 million years. Boaz is a field researcher, paleoanthropologist, and theorist. Amazingly good book, carefully written.

Hannes Alfvén, *Cosmic Plasmas* (1981)

Alfven became a heretic in rejecting the Big Bang. His explorations laid the foundation for the modern understanding of plasma physics. He was resurrected and placed in proper perspective by Eric Lerner in *The Big Bang Never Happened* (1991).

Nigel Davies, *The Ancient Kingdoms of Mexico* (1982)

Excluding the Maya, this gives a great overview of Mesoamerican history before the Spanish arrival.

Michael Coe, *The Maya* (7th ed. 2005)

An easy-to-read introduction to the Maya, from archaic beginnings through today; covers Olmecs and Guatemalan origins also. Provides much detail not found in other texts.

J. E. Thompson, *Maya Hieroglyphic Writing: Introduction* (1950)

An introduction to the Maya, their writing forms and calendar, from the dean of Maya studies. Very readable. Note that the narrative glyphs were still completely obscure in 1950.

Linda Schele and David Freidel, *A Forest of Kings* (1990)

Almost overwhelming details of religion, imagery, monuments, the personalities, and especially glyphs of the Yucatan Maya, with the period of AD 200 through AD 900 in great detail. See also *Maya Cosmos* (1993).

Dennis Tedlock, *Popol Vuh* (1996)

The best translation, with copious notes.

Charles Mann, *1491, New Revelations of the Americas before Columbus* (2006)

A comprehensive survey of the Americas before the arrival of Europeans. Mann is a science reporter, and willing to breach the 10,500 BC (10,900 BC) barrier held among US archaeologists. As a reporter he presents all sides of ongoing controversies, and presents conclusive evidence of the large population existing in the Americas before AD 1492.

Vine Delorian, *Red Earth, White Lies* (1995)

Deals with Indians in the Americas. It is mostly political, except that he makes a clear case both for why an 11,500 BC "invasion" of the Americas by Asiatics is unlikely, and why the notion is held with such tenacity. A number of other interesting topics which smack of a Young Earth philosophy.

Michael Grant, *The Ancient Mediterranean* (1969)

A very readable book tracing the civilizations of the Eastern Mediterranean, Greece, and Rome to about AD 400, with an emphasis on geography and trade. Grant includes relevant data which explains much more than traditional accounts of wars and conflicts do. Best set of maps also.

Geoffrey Bibby, *The Testimony of the Spade* (1956, 1974)

Overview of European archaeology, mostly from the historical perspective of actual discoveries by the first researchers. From Altamira through Roman times. Readable, and without philosophizing. Bibby dug at Dilmun in the Persian Gulf also.

Michael Cremo and Richard Thompson, *Forbidden Archaeology* (1993)

May also be available in shorter form as *Hidden History of...* An attempt, although religiously inspired, to prove that humanity has existed forever. Some valid data and as much invalid.

S. Warren Carey, *The Expanding Earth* (1976)

The claim is that 200 million years ago the Earth was half its present diameter. This smaller Earth was completely covered by Pangea, the ancestral supercontinent. Expansion split the Earth's old crust into the present-day continents and the spaces between filled with ocean water. In *Theories of the Earth and Universe* (1988) he deals with matter being created in the center of the Earth.

I. E. S. Edwards, *The Pyramids of Egypt* (1985)

Originally published in 1950, but updated in 1971. An excellent overview of early mastabas and pyramids through the First and Second Kingdom. Descriptions, photographs, diagrams and maps, and the relationship of construction between pyramids over time.

Peter Tompkins, *Secrets of the Great Pyramid* (1971)

Tompkins traces the strange fascination with the Great Pyramid of Giza over the centuries, and the research by others, often biased by insane theories. Before reading any other book on the pyramids, check this one out. Includes a large appendix by Livio Stecchini on measurements. This book will allow you to keep your sanity through the rantings of "pyramidiots."

E. G. Richards, *Mapping Time; the calendar and its history* (1998)

A lucid book which actually makes sense of calendars and timekeeping in antiquity, set within an historical discussion. Covers the background of astronomy, naming, and counting. Calendars are shown to be needed for religious observations and tax purposes, although as always the additional claim is made that they are needed by farmers to "know when to plant." The author is not always correct, and at times vague.

Joseph Lambert, *Traces of the Past; Unraveling the secrets of Archaeology through*

Chemistry (2001)

Stone, pottery, glass, and the metallurgy of bronze -- all detailed (and illustrated) with much more variety than the traditional simplifications. From Upper Paleolithic colorants through Mesopotamian beer brewing. Very good, easy to read. You will end up with a whole new appreciation for human ingenuity in the Neolithic -- the development of glazes, the variable metallurgy of bronze, the manufacture of Damascus steel.

Martin Jones, *The Molecule Hunt; archaeology and the search for ancient DNA* (1997)

Excellent book on the DNA (and other traces of organic chemicals) of the archaeological remains of plants, animals, humans, Neanderthals. Corrects many ideas about the Paleolithic and Neolithic world, development of agriculture, diets, and the migrations and relationships among populations. Notions of the "cold, barren, windswept" Beringia persist, but Indians are placed in the Americas 24,000 years ago, not just at 10,500 BC.

John McPhee, *Annals of the Former World* (1998)

A massive 700 page book on geology, as told from field trips with geologists and many anecdotes, which makes the book very readable, although you will at times be overwhelmed with the graphic details of the movements of mountains and the local US geography. Presents both sides of the plate tectonics issue, although mostly mainstream.

Vincent H. Malmstrom, *Cycles of the Sun, Mysteries of the Moon* (1997)

The book explains where the Olmecs came from (Guatemala), the development of the 260-day and 365-day calendar, and the Long Count, but it is guesswork based on computational results, rather than insights on how people think. Malmstrom attempts to demonstrate the existence of solar alignments of the ceremonial centers of central Mexico, which in itself goes far beyond all attempts at understanding by archaeologists. He is a geographer.

Clive Gamble, *The Palaeolithic Societies of Europe* (1999).

Gamble discusses the last Homo erectus and the following Neanderthals in Europe who developed a method of making cutting blades by knapping pre-shaped flint nodules. This was a development which may have derived from the Acheulean hand axe. For 300,000 years the blades are consistently the same shape and size. He notes that it was the process of knapping which was culturally carried forward, so that the Neanderthal mind was on the technique, not on the end product. Only this explains how the blades remain the same for such an unimaginable long time, and how no variations are ever developed. Yet despite this complete lack of imagination, the Neanderthals were thought to be effective scavengers.

Gamble also presents a review of glaciations and ice cores and oceanic oxygen isotope dating. He notes that hominids (H.erectus) did not invade Europe until after 500,000 BC, and suggests a combination of the prior existence of large African predators and a very variable climate as responsible for their absence. The cats disappeared a half

million years ago, but the variability of the climate in Western Europe, compared to the rest of the world, did not improve. The climate is blamed on the repeated extensive glaciation in northwestern Europe.

Jacques Bordaz, *Tools of the Old and New Stone Age* (1970).

An in-depth survey of the manufacture of stone tools in prehistory, concentrating mostly on Europe and Africa. Illustrated with details of forms and of knapping methods.

James Eades, Jr. *Elements of Orbital Transfer* (1965).

The mathematics has remained the same since 1925. I was interested in this because of what is known as a Hohmann transfer, which involves the use of an impulse to move a satellite from one orbit to another. Some form of this, specifically an impulse at a right angle to the original orbit, closely describes the effect of a set of electrical repulsive and attractive forces between planets. The mathematics for this particular case is of course not covered, but enough is presented for a number of differing cases to provide insight into the mechanics.

Samuel Gladstone *Sourcebook On Space Sciences* (1965).

Written under sponsorship of NASA. The mechanics has remained the same: trajectories, propulsion, and guidance systems. Many satellites are described, including plasma drive. This is followed by information on the Sun and solar system planets -- which is vastly different today.

Joseph Campbell *The Hero with a Thousand Faces* (1949, 2nd edition 1968).

A rambling compilation of sources bearing on world mythology. Apparently a source book for David Talbott. He follows Campbell's general schema, but Talbott assigns Campbell's generic hero to the planet Mars. This book is also the source for the "chaos monster" (page 286, 287, and Plate XXI "Chaos Monster and Sun God"). The book makes claims to mythology as providing the "profoundest metaphysical insights." This book presents the most serious misreading of mythology.

Edward Tripp, *The Meridian Handbook of Classical Mythology* (1970)

An alphabetical listing, 600 pages, but limited to Greek and Roman. A "must-have" book to check out who did what to whom and when, and who wrote about it in the past.

Thomas Bulfinch, *Mythology* (abridged, 1959)

Absolutely the classic narrative rendering of mythology; originally published in 1855 and 1863. The abridged edition by Edmund Fuller avoids the literary allusion and examples from the 19th century which have gone stale in the 20th century. Very easy reading.

James Frazer, *The Golden Bough* (1922 in 12 volumes, 1950 abridged as one volume)

Even the one-volume edition is overwhelming. The book is subtitled "A Study in Magic and Religion." Based mainly on texts from antiquity, and communications with

missionaries, Frazer leaves no stone unturned or uninspected in an effort to pinpoint human sacrifice everywhere, and kings slaughtered at the end of their term of office. But a classic nonetheless.

C. Leonard Woolley *The Sumerians* (1929).

By the excavator of Ur. A great, although inaccurate, overview of Sumer. Woolley tends to be off by a thousand years in his chronology, and has frequent racist opinions. There is another book of the same name by Samuel Kramer (1963) which is much better as an overview and more technical -- detailing language and schooling, for example.

Henriette Mertz *Pale Ink* (1953).

This is a translation with added comments of two Chinese documents, *Fu-sang* of about AD 500, and the *Classic of the Eastern Mountains* attributed to the emperor Yu of 2350 BC (but more likely dating from the Shang Dynasty, 1600 to 1100 BC). Both documents are partially available in translation. The originals have been neglected by the Chinese as being overly fanciful and by 19th century European scholars as unlikely -- for at that time the Europeans had no idea of the geography of North America, and in many instances, did not even have maps.

Mertz traces both texts geographically, including environments and distances, with amazing clarity. Most of the six legged animals remain unidentified (they seem to be crustaceans), but outside of some really exotic elements, everything is explained, where early 19th century French scholars had remained baffled. The 1979 edition corrects about 50 spelling errors.

Hayden White *Tropics of Discourse: Essays in Cultural Criticism* (1986).

The book deals with the literary representation of facts, or of history, or of anything needing expression (as in art criticism, of course). His analysis is based on the four grand tropes of classical rhetoric. This is the second-most marked up book in my possession. An earlier resource was **Northrop Frye, *Anatomy of Criticism* (1973)**, which develops along the same lines.

I. Bernard Cohen: *The Birth of a New Physics* (1985, revised 1960).

How the Copernican system grew out of the Aristotle's physics of antiquity, and how it influenced the development of the theories of Galileo, Kepler, and the breakthrough of Newton. The concepts of Galileo and Newton are discussed extensively, complete with the math involved, and also inertia, rotational momentum, the shape of the Earth, and the tides.

Bob Forrest: *A Guide to Velikovsky's Resources* (1985, revised 1987).

Bob Forrest provides a topic by topic critique of Velikovsky's *Worlds in Collision*. De Grazia, in *Iron Age of Mars* sums up the effort as follows: "I believe Forrest to be a thoroughgoing honest, if carping, critic. He has done a service in reining in some of Velikovsky's more reckless readings and remarks. In my opinion Forrest asks too much.

Legend and myth are suggestive, not conclusive. (So largely are histories and archaeology.) Velikovsky's knowledge of the Bible and its exegesis, of calendrics, astronomy, and psychoanalytic theory permits him to formulate situations in ways deemed conventionally impermissible."

Other Books Mentioned *En Passant*

(periodicals and ancient documents excluded)

Chapter 1: Introduction

- Giorgio de Santillana and Hertha von Dechend, *Hamlet's Mill: an Essay on Myth and the Frame of Time* (1977).
- Anthony Aveni, *Skywatchers of Ancient Mexico* (1980)
- James Hogan, *Kicking the Sacred Cow* (2004)
- Donald W. Goldsmith, *Scientists Confront Velikovsky* (1977).
- Carl Sagan, *Broca's Brain* (1979)
- Shane Mage *Velikovsky and His Critics* (1978)
- Edward T. Hall, *Beyond Culture* (1976)
- Alfred de Grazia, Ralph Juergens, and Livio Stecchini, *The Velikovsky Affair* (1966, 1978)
- Charles Ginenthal, *Carl Sagan and Immanuel Velikovsky* (1995)
- Eric Lerner, *The Big Bang Never Happened* (1991)
- Hilton Ratcliffe, *The Virtue of Heresy: Confessions of a Dissident Astronomer* (2007).
- Michael Gordin, *The Pseudoscience Wars and the Birth of the Modern Fringe* (2012)
- Laird Scranton, *The Velikovsky Heresies: Worlds in Collision and Ancient Catastrophes Revisited* (2012)

Chapter 2: A Synopsis

- Gary Gilligan, *An Ancient World in Chaos* (2008)
- Donald W. Patten and Samuel R. Windsor, *The Mars-Earth Wars* (1996)
- John Ackerman, *Firmament: Recent Catastrophic History of the Earth* (1996), *Chaos: A New Solar System Paradigm* (2000), and *Peleh: Hidden Knowledge* (2006)
- Julian Jaynes, *The Origin of Consciousness in the Breakdown of the Bicameral Mind* (1976)

Chapter 3: The Osiris Mystery

- Tom Van Flandern, *Dark Matter, Missing Planets and New Comets* (1999)
- Dwardu Cardona, *God Star* (2006)
- Jean Markale, *The Celts, Uncovering the Mythic and Historic Origins of Western Culture* (1978)

- Peter James, *Centuries of Darkness* (1991)
- James Hogan, *Catastrophes, Chaos and Convolutions* (2005)

Chapter 4: The Nevada Conference

- William Matthews, *Fossils* (1962)
- Peter Douglas Ward, *Gorgon: Paleontology, Obsession, and the Greatest Catastrophe in Earth's History* (2004)
- Douglas H. Erwin, *Extinction, How Life on Earth Nearly Ended 250 Million Years ago* (2006)

Chapter 5: The Absu and Speculation

- Herman Kahn, *World Economic Development: 1979 and Beyond* (1979)
- Thomas Kuhn, *The Structure of Scientific Revolutions* (1970)
- Michael Kaplan and Ellen Kaplan, *Chances Are* (2006)
- Hannes Alfvén, *Cosmical Electrodynamics* (1950, 1963), and *On The Origin of the Solar System* (1954)
- J. H. Piddington *Cosmic Electrodynamics* (1969)
- Anthony L. Peratt *Physics of the Plasma Universe* (1992)
- Leonard W. King, *Legends of Babylon and Egypt* (1918)
- Joseph Lambert, *Traces of the Past* (2001)
- Richard Rudgley, *The Lost Civilizations of the Stone Age* (1999)
- Alfred de Grazia, *The Iron Age of Mars* (2009)
- Samuel Butler, *The Authoress of the Odyssey* (1897, 1922)

Chapter 6: Alternate Cosmology

- Bill Bryson, *A Short History of Nearly Everything* (2003)
- David Berlinski, *A Tour of the Calculus* (1996)
- Lynn Margulis and Dorion Sagan, *What Is Life?* (1995)
- Boyce Rensberger, *Life itself: Exploring the realm of the living cell* (1996)

Chapter 7: Ice Ages and Humans

- Clive Gamble, *The Palaeolithic Societies of Europe* (1999)
- Robin McKie, *The Dawn of Man* (2000)
- James Shreeve, *The Neanderthal Enigma* (1995)
- Charles Mann, *1491, New Revelations of the Americas before Columbus* (2006)

Chapter 8: Tunguska and Chicxulub

- Sean Carroll, *Remarkable Creatures* (2009)
- Mel Waskin, *Mrs. O'Leary's Comet* (1985)

Chapter 9: Event of the Younger Dryas

- Richard Firestone, Allen West, and Simon Warwick-Smith, *The Cycle of Cosmic Catastrophes* (2006)
- J. D. Cobine, *Gaseous Conductors- Theory and Engineering Applications* (1958)
- J. J. and G. P. Thomson *Conduction of Electricity through Gases Vol. 11* (1969)
- E. J. Hellund *The Plasma State* (1961)

Chapter 10: A Timeline and Gimbutas

- Marija Gimbutas, *The Civilization of the Goddess* (1991)
- Denis Vialou, *Prehistoric Art and Civilization* (1996)
- Charles Ginenthal, *The Extinction of the Mammoth* (1997)
- Cynthia Eller *The Myth of Matriarchal Prehistory* (2000)

Chapter 11: Saturn and Archaeology

- Jacquetta Kawkes, *Prehistory* (1965)
- André Leroi-Gourhan, *The Art of Prehistoric Man in Western Europe* (1968)
- James Mellaart, *Catal Huyuk* (1967)
- Jean Clottes and Jean Courtin, *The Cave Beneath the Sea: Paleolithic Images at Cosquer* (1996)
- James Mellaart, et alii, *The Goddess from Anatolia* (1989)
- Dennis Moore, *North American Stone Bird Effigy, Field Guide, Finding and Identifying* (2010)

Chapter 12: The Peratt Column

- Ralph L. Roys, *The Book of Chilam Balam of Chumayel* (1933)
- Antonio Mediz Bolio, *The Book of Chilam Balam of Chumayel* (1930) in Spanish
- Alfred Watkins, *Early British Trackways, Moats, Mounds, Camps and Sites* (1922)
- Graham Hancock, *Underworld* (2002)
- Joseph Needham, *Science and Civilization in China* (1979)
- B.H. Chamberlain (tr.), *The Kojiki* (1882)
- Joan Connelly , *The Parthenon Enigma* (2014)

Chapter 13: The Creation

- Bernardino Verastique, *Michoacan and Eden* (2000)
- David Talbott, *Symbols of an Alien Sky* slide presentation (1997)
- James Legge (tr.), *The I Ching* (1882)
- Wendy Doniger O'Flaherty *Hindu Myths* (1975)

Chapter 14: The Start of Time

- Bob Berman, *Cosmic Adventure* (1998)
- Ev Cochrane, *Martian Metamorphoses* (1997)
- Patrick Moore, *Venus* (2002)
- William Whiston (tr., AD 1737) Josephus, *The Antiquity of the Jews* (AD 93)
- I.E.S. Edwards, *The Pyramids of Egypt* (1972)

Chapter 15: The Era of the Gods

- William Stukeley, *Stonehenge, A Temple Restored to the British Druids* (1740)
- Jean-Pierre Mohen, *The World of Megaliths* (tr. 1990)
- Guy Davenport, *Geography of the Imagination* (1981)
- Pierre Mereaux, *Carnac: Des Pierres Pour Les Vivants* (1992),
- Roger Joussaume, *Dolmens pour les Morts* (1985?)

Chapter 16: The World Flood

- Hesiod, *Theogony* (800 BC) (Norman O. Brown tr. 1953)
- Rachel Carson, *The Edge of the Sea* (1955)
- D.A. Cyr, *Annular Space Dust* (1968)
- Zecharia Sitchin, *Divine Encounters* (1996)

Recovering the Lost World, A Saturnian Cosmology -- Jno Cook

Appendix P: Links to Saturnian Web Sites.

\$Revision: 1.21 \$ (links.php)
Links verified November 2014

A List of Links

[\[saturniancosmology.org/juergens.htm\]](http://saturniancosmology.org/juergens.htm)

Ralph Juergens "Reconciling Celestial Mechanics and Velikovskian Catastrophism" Pensee (1972). Find some additional articles at the *kronos-press* site, below. See also the two articles on "the Moon and Mars," part 1 and part 2 at

[\[saturniancosmology.org/juergensa.htm\]](http://saturniancosmology.org/juergensa.htm) and [\[saturniancosmology.org/juergensb.htm\]](http://saturniancosmology.org/juergensb.htm)

[\[www.kronos-press.com\]](http://www.kronos-press.com)

Kronos Press -- Books; and a number of articles by Ralph Juergens originally published in Kronos Magazine (and Pensee). Index to the writings of Velikovsky.

[\[www.q-mag.org\]](http://www.q-mag.org)

Alfred and Anne-Marie de Grazia's Q-magazine site: Quantavolution presented as an on-line magazine. Numerous news articles and presentations, plus five years' worth of European conferences.

[\[plasmacosmology.net\]](http://plasmacosmology.net)

A narrative description, including some catastrophism and mythology. A very extensive site, written in a summary, easy to read, style. The mythology follows Dave Talbott closely.

[\[plasmaresources.com\]](http://plasmaresources.com)

Another site equal in scope and general interest, run by David Smith, AU. See especially his Columbia Disaster notes at [\[www.columbiadisaster.info\]](http://www.columbiadisaster.info).

[\[sites.google.com/site/cosmologyquest/default\]](http://sites.google.com/site/cosmologyquest/default)

A very readable overview of cosmology and plasma theory which generally cuts across the handed-down "science" to zero-in on essentials. By Michael Suede.

[\[www.sis-group.org.uk\]](http://www.sis-group.org.uk)

Society for Interdisciplinary Studies (SIS) site. The classic site for continued attempts at straightening out the chronology of the Middle East which was first questioned by Velikovsky in the 50s and 60s. Also largely concerned with catastrophism, but almost entirely based on fugitive comets.

[\[www.plasma-universe.com\]](http://www.plasma-universe.com)

An extensive collection on plasma theory, developed and maintained as a Wiki site by Ian Tresman of Society for Interdisciplinary Studies.

[\[www.holoscience.com\]](http://www.holoscience.com)

Holoscience, Wal Thornhill's "Electric Universe" site. Plasma theories at planetary and galactic levels and experimental work applied to the Saturnian Theory. Working in concert with Talbott (see "Thunderbolts" below).

[\[www.thunderbolts.info\]](http://www.thunderbolts.info)

The parent site to the current endeavors of Dave Talbott and friends. A "picture of the day" feature which always amazes, plus an archive, and collected essays by other people. Promos for recent books and book series. Videos are also available on line (plus DVDs for sale). Connection to a wide-ranging forum on matters of "plasma and electricity in space."

[\[www.velikovsky.info\]](http://www.velikovsky.info)

The "Velikovsky Encyclopedia" is a recent endeavor (2009) to provide resources related to the writings and ideas of Immanuel Velikovsky -- under the unique premise that both sides of the "controversy" could be presented (which in effect will go to prove Velikovsky's case). The authors and archivists write under a thin veneer of anonymity. An interesting tangle of pros and cons.

[\[www.aeonjournal.com\]](http://www.aeonjournal.com)

Aeon (magazine) site. A promotion of the Saturn Theory; started by David Talbott. Editors: Ev Cochrane and Dwardu Cardona. Cardona is an imaginative and convincing writer. Cochrane is a tireless researcher. This site periodically disappears off the map. Standing still since 2005.

[\[othergroup.net\]](http://othergroup.net)

This is a collection of essays and shorter snippets mostly by others for and against alternative cosmologies. Some have no common link except as speculation. Some weird things are just outrageously funny.

[\[othergroup.net/thoth\]](http://othergroup.net/thoth)

Thoth Newsletter from the Kronia Magazine site -- what was a standard in promoting the Saturnian Polar Configuration. Kronia.com was discontinued 3/2010. But the complete set of the Internet publication "Thoth" can be retrieved from here (there are two other locations).

[\[ContraryBooks.Com\]](http://ContraryBooks.Com)

A listing of books in catastrophism and alternative cosmologies, and some reviews.

[\[www.electric-cosmos.org/indexOLD.htm\]](http://www.electric-cosmos.org/indexOLD.htm)

Don Scott's great explanation of plasma theories. An electrical engineer, avid astronomer, and supporter of Saturnian Theory. The link above connects to an earlier version of his book "The Electric Sky" (2006). Try also [\[www.electric-cosmos.org/index.htm\]](http://www.electric-cosmos.org/index.htm)

[\[www.mikamar.biz\]](http://www.mikamar.biz)

Michael Armstrong's clearinghouse for books on the Polar Configuration and Velikovskian matters, and "Products supporting Prehistoric Reconstruction and Plasma

Cosmology," including used books. A valuable resource.

[\[www.velikovskian.com\]](http://www.velikovskian.com) [Japanese script, hijacked 11/2014]

A journal of work stemming from the research of Velikovsky. Offers a number of books also. Charles Ginenthal (ed.), Lynn E. Rose, Gunnar Heinsohn, others. Has been standing still for a couple of years.

[\[immanuelvelikovsky.com\]](http://immanuelvelikovsky.com)

A site featuring the books of Ginenthal in pdf format, including all four issues of *Pillars of the Past*.

[\[www.metaresearch.org\]](http://www.metaresearch.org)

Tom Van Flandern, of *Dark Matter, Missing Planets and New Comets* (1999) fame. Van Flandern is an astronomer, with interesting theories on planet formation, and other topics approaching the catastrophic from a mechanical (gravitational) point of view. He is also the top theorist in gravitational matters.

[\[www.haltonarp.com\]](http://www.haltonarp.com)

Galactic red-shift and recession. See the book list.

[\[www.science-frontiers.com\]](http://www.science-frontiers.com)

"Strange Science, Bizarre Biophysics, Anomalous Astronomy" -- from the pages of the world's scientific journals -- always interesting reading.

[\[www.maverickscience.com\]](http://www.maverickscience.com)

Ev Cochrane's website (editor at Aeon). Includes some of his outstanding articles.

[\[www.catastrophism.com\]](http://www.catastrophism.com)

Actually a CDROM offering of past literature on the subject.

[\[plasmauniverse.info\]](http://plasmauniverse.info)

Material by Anthony Peratt of Experimental Programs at Los Alamos National Laboratory. Peratt is one of the world's leading pioneers in plasma physics and plasma cosmology. Peratt's papers on the petroglyphs and the south polar plasma column are located here at this site, but hard to ferret out.

Look under NearEarth.html for

- A. L. Peratt, *Characteristics for the Occurrence of a High-Current, Z-Pinch Aurora as Recorded in Antiquity*

- A.L. Peratt, J. McGovern, A.H. Qöyawayma, M.A. Van der Sluijs, and M.G. Peratt, *Characteristics for the Occurrence of a High-Current, Z-Pinch Aurora as Recorded in Antiquity, Part II: Directionality and Source*.

[\[www.the-electric-universe.info\]](http://www.the-electric-universe.info)

Electric Universe -- another view. Site of Hungarian physicist Laszlo Koertvelyessy.

[\[www.varchive.org\]](http://www.varchive.org)

The Velikovsky archive of unpublished documents by Jan Sammer.

[\[www.earth-history.com\]](http://www.earth-history.com)

A site of L.C. Geerts which includes a great number of Sumerian and Akkadian source documents. Geerts follows Sitchin.

[\[www.mythopedia.info\]](http://www.mythopedia.info)

Marinus van der Sluijs's Mythopedia -- originally based entirely on the image and story evidence of a Polar Configuration, but now given over to an auroral plasma to explain

all celestial phenomena of remote antiquity. Very professional, very verbose, and very wrong. It is a book (or books) in progress.

[\[www.bearfabrique.org\]](http://www.bearfabrique.org)

Ted Holden's site discusses the improbability of dinosaurs being able to move and live with the gravity we experience today. Nice article on the flight capabilities of prehistoric birds. Large collection of other source material. A few political items.

[\[www.grazian-archive.com\]](http://www.grazian-archive.com)

Alfred de Grazia's writings. Everything is in pdf as complete books. *Chaos and Creation* sort of parallels these pages, except for its Young Earth basis. Totally engaging, is *God's Fire*. This is the story of Moses and the Exodus (1500 BC). Among other things, de Grazia reviews works by every biographer of Moses since antiquity, the operation of the Ark, the organization of the camps, the details of the whole migration, the electrical tricks of Moses, his interaction with Yahweh, and the character and psychology of Moses. See the Appendix "List of Books" for more.

[\[sites.google.com/site/dragonstormproject\]](http://sites.google.com/site/dragonstormproject)

by Dennis Cox: "Recent impact evidence in the Americas. Extensive, map-based graphics." Molten mountaintops and ridges: Cox has investigated altered landforms, attributed by him to the event at the start of the Younger Dryas. Cox accidentally adds burn marks due to Mars in the 8th and 7th century BC in northern Mexico. See also

[\[https://cometstorm.wordpress.com\]](https://cometstorm.wordpress.com)

[\[www.eu-geology.com\]](http://www.eu-geology.com)

Michael Steinbacher, a photographer, has been investigating the western landscape for a number of years in light of the alternative cosmology of the Electric Universe.

Steinbacher sees things we do not see.

[\[www.emmetsweeney.net\]](http://www.emmetsweeney.net)

[Link dead 8/2014, but try Amazon) Emmet John Sweeney is author of some eight books on alternative cosmological detail, mainly based on Velikovsky and Gunner Heinsohn. Sweeney takes exception to both. See especially the four book series "Ages in Alignment" which proposes a world history not unlike this one. Sweeney proposes that an initial contact with Venus produced the world flood. He also places most dates much later.

[\[www.creationism.org/patten/PattenMarsEarthWars/index.htm\]](http://www.creationism.org/patten/PattenMarsEarthWars/index.htm)

Donald W. Patten and Samuel R. Windsor, authors of *The Mars-Earth Wars* (1996), which may be found here. This is a well-written piece about the intersection of the orbit of Earth and Mars through the 8th and 7th century BC. The authors are physical scientist and engineers, making their theories much more believable.

[\[www.firmament-chaos.com\]](http://www.firmament-chaos.com)

John Ackerman, *Firmament: Recent Catastrophic History of the Earth* (1996), *Chaos: A New Solar System Paradigm* (2000), and *Peleh: Hidden Knowledge* establishes the repeated meetings of Earth and Mars (and Venus) primarily from Vedic sources.

Ackerman is a physicist.

[\[www.gks.uk.com\]](http://www.gks.uk.com)

Promotes the book *An Ancient World in Chaos* (2008) by Gary Gilligan with a dozen

synoptic pages from its contents. An analysis of Egyptian iconography, refreshingly direct and unpretentious, which assigns the Gods of Egypt to the known planets and Hathor to an equatorial ring system. I do not agree with his particular assignment of Gods and planets, or the celestial mechanics.

[\[www.saturnian.org\]](http://www.saturnian.org)

Saturnian Org. Standing still for a decade -- broken links and a few papers posted.

[\[www.julianjaynes.org\]](http://www.julianjaynes.org)

Julian Jaynes society. Additional articles, books.

[\[www.pibburns.com\]](http://www.pibburns.com)

Philip Burns: Velikovsky, catastrophe, meteors, Venus transits and the flu. Exceptions to Velikovsky and the Saturnian model.

[\[www.tim-thompson.com\]](http://www.tim-thompson.com)

Another site which argues against the Saturnian model. This by the astrophysicist Tim Thompson. Good, except when it is about Tim Thompson.

[\[www.expanding-earth.org\]](http://www.expanding-earth.org)

A starter site by Lawrence Myers based on S. Warren Carey's theory of an expanding Earth. See also the Expanding Earth Theories at [\[www.xearththeory.com\]](http://www.xearththeory.com), (and as many debunkings).

[\[personal.eunet.fi/pp/tilmari\]](http://personal.eunet.fi/pp/tilmari)

The website of Timo Niroma which in the 1990's proposed a detailed overview of the 2349 BC and 2193 BC events. Additionally Timo is credited with some of the earliest investigation of the effect of Jupiter on Sunspot cycles, for which see

[\[personal.inet.fi/tiede/tilmari\]](http://personal.inet.fi/tiede/tilmari).

recent additions...

[\[www.paleobirdeffigies.com\]](http://www.paleobirdeffigies.com)

Dennis Moore's site of chipped stone birds found in middle lower Michigan.

[\[sumerian.org\]](http://sumerian.org)

John Halloran's in depth site on Sumerian. Great.

[\[www.planetamnesia.com\]](http://www.planetamnesia.com)

Andrew Fitts's site exploring Cultural Amnesia. Extensive, key concepts, and a no-hold-barred FAQ. Supports the reasoning of this site, Saturniancosmology.org ("Recovering the Lost World").

[\[mythsarehistory.com\]](http://mythsarehistory.com)

Julian West's site exploring myths. An incomplete chronology, but a great encyclopedia of images from diverse sources. See also [\[facebook.com/mythsarehistory\]](https://facebook.com/mythsarehistory)

[\[tiki-toki.com/timeline/entry/250694\]](http://tiki-toki.com/timeline/entry/250694)

A time line of events by Kim Gibson, presented in graphical form with various features for viewing. And also

[\[vimeo.com/user35855839/videos\]](https://vimeo.com/user35855839/videos)

A video presentation of the Saturnian system.
